- Finding a node that contains a given data, or locating the place where a new node should be inserted may require scanning most or all of the list elements.
- The list element does not have to occupy contiguous memory.
- Adding, insertion or deletion of list elements can be accomplished with the minimal disruption of neighbouring nodes.

Single-linked List

List in which each node contains only one link field.

Node structure

```
struct
{
int ele;
struct node * next;
};
```

typedef struct node Node;

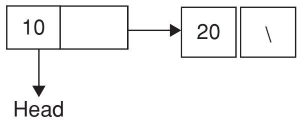
Creating a linked list with two nodes of type list node

Creating a linked list with 2 nodes
struct node

```
{
Int ele;
struct node * next ;
};
typedef struct node Node ;
Node * ptr1, * ptr2;
ptr1 = getnode ();
ptr2 = getnode ();
if((ptr1) && (ptr2))
{
Printf("No memory");
exit(1);
}
Ptr1 → ele = 10;
```

```
Ptr1 → next = ptr2;
Ptr2 → ele = 20;
Ptr2 → next = NULL;
Head = ptr1;
```

the linked list appears as below



Operations on SLL (single-linked list)

- Insert at Head
- Insert at Tail
- Insert in Middle
- Delete Head
- Delete Tail
- Delete Middle
- Search
- Display

Declare two special pointers called head and tail as follows:
Node *Head, *Tail;
Head = Tail = NULL;

Head or tail is NULL represents list is empty.
Steps for Insertion:

1. Allocate memory
2. Read data
3. Adjust references

Insert head element

```
1. void ins _ Head (int x)
2. {
3. Node *temp;
4. temp = (Node *) malloc(sizeof (Node));
5. temp → ele = x;
6. temp → next = Head;
7. Head = temp;
8. if (Tail = = NULL)
9. Tail = Head;
10 }
```

- Step 4 allocates memory
- Step 5 read data
- Steps from 6 to 9 adjust reference
- 'if' condition represents first insertion

Insert tail element

```
1. void ins_tail (int x)
2. {
3. Node *temp;
4. temp = (Node *) malloc (sizeof (Node));
5. temp → ele = x;
6. temp → next = NULL;
7. Tail = temp;
8. if (Head = = NULL)
9. Head = Tail;
10. }
```

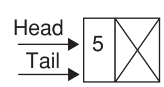
- Step 4 allocates memory
- Step 5 read data
- Steps from 6 to 9 adjust reference
- 'if' condition represents first insertion

Insert in middle/random position of list

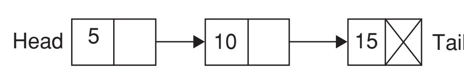
```
1. void ins _ mid (int n, int pos)
2. {
   int i = 1;
3. Node  *  temp,  N,  P;  //N,P  represent
   previous //& next nodes
4. if (Head == NULL)
5. {
6. ins _ head(n);
7. return;
8. }
9. temp = (Node *) malloc(sizeof(Node));
10. temp → ele = n;
11. P = head;
12. while (i < pos -1)
13. {
   P = P → next;
   i++;
   }
14. N = P → next;
15. temp → next = N;
16. P → next = temp;
17. }
```

- step 4 checks, whether the insertion is into an empty list.
- If list is empty, invokes ins–head( ) function.
- If list is not empty, then step 9 allocates memory.
- Step 10 reads data.
- Steps from 11 to 14 make the reference to the previous and next nodes of new node to be inserted.
- Steps 15 and 16 create the reference to new node from previous node and from new node to next node.

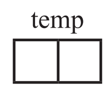
Example 1: Head = Tail = NULL
$n = 5$, P = NULL;
Here the list is empty. So,



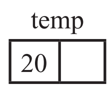
Example 2:



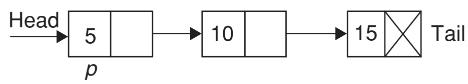
Insert element (n) 20 at position(pos) 3.
In current list, element 5 is the first element, 10 is the second and 15 is the third element.
To insert an element at pos = 3, the new node has to be placed between elements 10 and 15.
Condition in step 4 is false so step 9 executes and allocates memory.



On completion of step 10 –



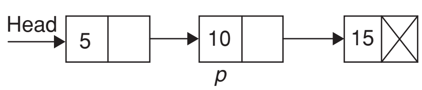
Step 11



Step 12, 13

```
While (i < pos – 1)
{
P = P → next;
i++;
}
i < pos
1 < 2
```

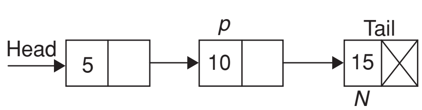
Condition true, so



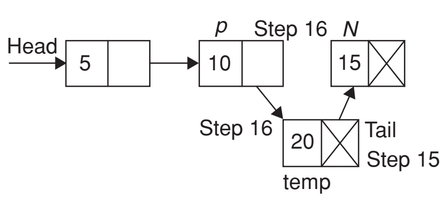
i becomes 2,

2 < 2 // condition false

Step 14 makes a reference to next of previous element.



Steps 15 and 16 execute as follows:



Now the element 20 becomes the 3rd element in the list.

Deletion

- Identify the node
- Adjust the links, such that deallocation of that node does not make the list as unconnected components.
- Return/display element to delete.
- Deallocate memory.

Delete head element

```
1. void del _ head()
2. {
3. int x;
   Node * temp;
4. if (Head = = NULL)
5. {
6. printf("List empty");
7. return;
8. }
9. x = Head → ele;
10. temp = Head;
11. if (Head = = Tail)
12. Head = Tail = NULL;
13. else
14. Head = Head → next;
15. printf ("Deleted element "%d", x);
16. free(temp);
17. }
```

Step 4	–	Checks for list empty
Step 9	–	Reads element to delete
Step 10	–	Head referred by temp pointer
Step 11	–	Checks for last deletion
Step 14	–	Moves the head pointer to next element in the list
Step 15	–	Displays element to delete
Step 16	–	Deallocates memory

Delete tail element

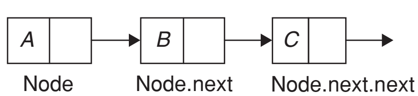
```
1. void del _ tail()
2. {
3. int x;
4. Node * temp;
5. if (Head = = NULL)
6. {
7. printf("\n list empty")
8. return ;
9. }
10. temp = Head;
11. while(temp → next ! = Tail)
12. temp = temp → next;
13. x = Tail → ele;
14. Tail = temp;
15. temp = temp → next;
16. Tail → next = NULL;
17. printf("\n Deleted element : %d", x)
18. free (temp);
19. }
```

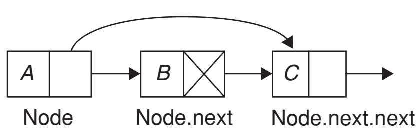
Step 4	– Checks for list empty
Step 10, 11, 12	– Move the temp pointer to last but one node of the list
Step 13	– Reads tail element to delete
Step 14	– Moves tail pointer to last but one node
Step 15	– Moves the temp pointer to last node of the list
Step 16	– Removes the reference from tail node to temp node, i.e., tail node becomes the last element
Step 17	– Displays elements to delete
Step 18	– Deallocate memory

Delete middle element

```
1. void del _ mid (int pos)
2. {
3. int i = 1, x;
4. Node * temp P, N;
5. if(Head = = NULL)
6. {
7. printf ("\n list empty")
8. return;
9. }
10. P = head;
11. while (i < pos -1)
12. {
   P = P → next;
   i++ ;
   }
13. temp = P → next;
14. N = temp → next;
15. P → next = N;
16. x = temp → ele;
17. printf("\n Element to Delete %d", x);
18. free(temp);
19. }
```

Step 5 – Checks for empty list
Step 10, 11, 12 – Move previous pointer *P* to previous node of node to delete.
Step 13 – Temp points to node to delete
Step 14 – N points to temp next
Step 15 – Creates link from *P* to *N*
Steps 16, 17, 18 – Read and display elements to delete and deallocate memory.





Linked list using dynamic variables

Node in the linked list contains data part that is ele and link part which points to the next node, and some other external pointer will be pointing to this as these take some storage, a programmer when creating a list, should check with the available storage. For this we make use of get node ()

Function which is defined as follows:

```
struct node
{
int ele
struct node * next ;
};
typedef struct node Node;
Node getnode ()
{
Node ptr;
ptr = (Node *) malloc (size of (struct node)):
return (ptr);
}
```

If ptr returns NULL, then it is underflow (there is no available memory) otherwise, it returns start address of memory location.

Search an element

```
1. void search (int x)
2. {
3. Node * temp = head;
4. int  c = 1;
5. while (temp! = NULL)
6. {
7. if (temp → ele = = x)
8. {
9. printf("\n Element found at % d", c);
10. break;
11. }
12. c++;
13. }
14. if (temp = = NULL)
15. printf("\n search unsuccessful");
16. }
```

Step 7 – Checks temp data with search element. Repeats this step until the element is found or reaches the last node
Step 9 – Displays the position of search element in the list, if found
Step 14, 15 – Represents search element not exists in list

Display

```
1. void display ( )
2. {
3. Node *temp = Head;
4. printf("\n list elements: ");
5. while (temp ! = NULL)
6. {
7. printf("%d", temp → ele);
8. temp = temp → next;
9. }
10. }
```

Step 7 – Displays temp data
Step 8 – Moves temp pointer to next node

Algorithm to reverse direction of all links of singly liked list

Consider a linked list '*L*' with head as pointer pointing to the first node contains data element 'ele' and a pointer called 'next' which points to the next node.

Reverse is the routine which will reverse the list, there are three node pointers *P*, *Q*, *R* with *P* pointing to the first node, *Q* pointing to NULL.

```
1. START
2. if (P = NULL)
   1. print ("List is null");
   2. Exit
3. While (P)
4. R = Q;
5. Q = P;
6. P = P → next;
7. Q → next = R
8. End While
9. Head = Q;
10. STOP
```

Double-linked List (DLL)

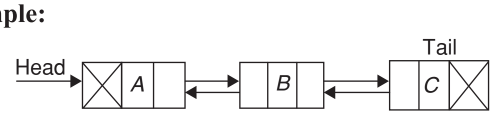
Double-linked list is a linked list in which, each node contains data part and two link fields.

Node structure:

```
struct Dnode
{
struct Dnode *prev;
int ele;
struct Dnode *next;
};
```

- prev – points to previous node in list
- next – points to next node in list
- The operations which can be performed in SLL can also be preformed on DLL.
- The major difference is that we have to adjust double reference as compared to SLL.
- We can traverse or display the list elements in forward as well as in reverse direction.

Example:



Circular-linked List (CLL)

Circular-linked list is completely same as SLL, except, in CLL the last (Tail) node points to first (Head) node of list.

So, the Insertion and Deletion operation at Head and Tail are little different from SLL.

Double Circular-linked List (DCL)

Double circular-linked list can be traversed in both directions again and again. DCL is very similar to DLL, except the last node's next pointer points to first node of list and first node's previous pointer points to last node of list.

So, the insertion and deletion operations at head and tail in DCL are little different in adjusting the reference as compared to DLL.

Storing ordered table as linked list: The table is stored as a linked list, it is retrieved and stored with two pointers, one pointer will point to node holding a record having the smallest key and other pointer performs the search.

Stack

A stack is a last in first out (LIFO) abstract data type and data structure. A stack can have any abstract data type as an element, but is characterized by only two fundamental operations.

√ PUSH
√ POP

- The PUSH operation adds an item to the top of the stack, hiding any items already on the stack or initializing the stack if it is empty.
- The POP operation removes an item from the top of the stack, and returns the poped value to the caller.
- Elements are removed from the stack in the reverse order to the order of their insertion. Therefore, the lower elements are those that have been on the stack for longest period.

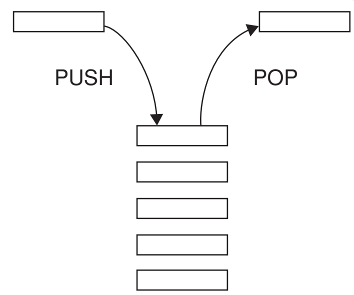


Figure 1 Simple representation of a stack

Implementation

A stack can be easily implemented either through an array or a linked list. The user is only allowed to POP or PUSH items onto the array (or) linked list.

1. **Array Implementation:** Array implementation aims to create an array where the first element inserted is placed st[0] which will be deleted last.

   The program must keep track of position top (last) element of stack.

   Operations

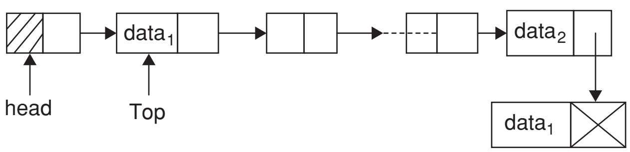
   Initially Top = –1;//represents stack empty

```
(i) Push (S, N, TOP, x)
    {
    if (TOP = = N - 1)
    printf("overflow");
    else
    TOP = TOP + 1;
    S[TOP] = x;
    }
(ii) POP (S, N, TOP, x)
    {
    if (TOP = = -1)
    printf("underflow");
    else
    x = S[TOP]
    TOP = TOP - 1
    return x;
    }
```

2. **Dynamic Implementation:** The Array implementation is also called static implementation, because the stack size is fixed.
   The stack implementation using linked list is called dynamic implementation, because the stack size can grow and shrink as the elements added or removed from the stack.
   - The PUSH operation on stack is same as insert head in SLL.
   - The POP operation is same as delete head in SLL.

Algorithm to add and delete to a link stack and link queue

Link stack:



The linked stack with head and top pointers is shown above

The algorithm to push the elements into stack is given below, the method push (item)

Steps:

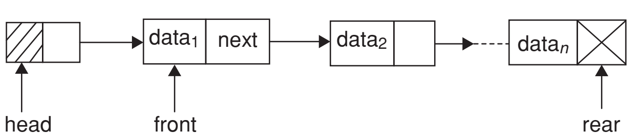
```
1. ptr = getnode (Node)
2. ptr.data = item
3. ptr.next = Top
4. Top = new
5. Head.next = Top
6. Stop.
```

for deletion of elements from stack, its algorithm is pop(), it is given below

Steps:

```
1. if (Top = NULL)
   1. print "stack is empty"
   2. exit
2. Else
   1. ptr = Top.next
   2. item = Top.data
   3. Head.next = ptr
   4. Top = ptr
3. End if
4. Stop.
```

Linked queue representation



The linked queue with head, front and rear point is shown above.

The algorithm to enqueue the elements into queue is given below, the method enqueue (item)

Steps:

```
1. ptr = getNode (Node)
2. ptr.data = item
3. ptr.next = NULL
4. if (front = NULL)
      front = ptr
      else
      rear.next = ptr;
5. end if
6. rear = ptr
7. Stop
```

For deletion of elements from queue that is ptr dequeue () is given below

Steps:

```
1. if (front = NULL)
   1. print "underflow".
   2. exit
2. ptr = front;
3. front = ptr.next
4. Head.next = front
5. item = ptr.data
6. free(ptr)
7. end.
```

Uses of Stack

- Function calls: When a function is called all local storage for the function is allocated on system 'stack', and return address also pushed on to system stack.
- Recursion stacks can be used to implement recursion if the programming language does not provide recursion facility.
- Reversing a list
- Parsing: Stacks are used by compilers to check the syntax of program.
- For evaluating expressions.

Expression Notations

Infix expression: Here binary operator comes between the operands.

Postfix expression: Here the binary operator comes after both the operands.

Example: *ab+*

Prefix expression: Here the binary operator comes before both the operands.

Example: *+ab*

Infix to postfix conversion

- If operand, output to postfix expression
- If operator, push it onto stack
- In case of parenthesis, when an opening parenthesis is read, it is pushed onto stack and when a closing parenthesis is read, all operators up to the first opening parenthesis must be popped from the stack into the post fix notation.

Example: $(A + (B - C))*D$

i/p	Postfix notation	Stack
(		(
A	*A*	(
+	*A*	(+
(	*A*	(+(
B	*AB*	(+(
–	*AB*	(+(–
C	*ABC*	(+(–
)	*ABC*–	(+
)	*ABC*–+	–
*	*ABC*–+	*
D	*ABC*–+*D*	*
	ABC–+*D**	

Evaluation of postfix expression

We use operand stack for evaluation. Scan the post fix expression,

- When an operand encounters while scanning, push on to stack.
- While scanning post fix expression, if operator found then
  - Pop top two operands from stack
  - Perform the operation on those two operands
  - Push, result on to stack top
- Finally, the stack contains only one value, which represents result of the expression.

Example: 6 2 3 + – 3 8 2 / + 2 3 +

Symbol	OP1	OP2	Value	Operand stack
6				6
2				6, 2
3				6, 2, 3
+	2	3	5	6,5
–	6	5		1
3				1, 3
8				1, 3, 8
2				1, 3, 8, 2
/	8	2	4	1, 3, 4
+	3	4	7	1, 7
*	1	7	7	7
2				7, 2
*	7	2	14	14
3				14, 3
+	14	3		17

Result is 17.

Performing add, delete operations on stack (multiple stack)

Let us consider an array whose size is 'max'
with multiple stack *A*, *B* having top *A* and top *B*, push and pop operations on one stack *A* is given below.

Algorithm for push A(x)

Initially *A*[Max], top *A* = –1, top *B* = MAX;

```
1. if (top A = top B)
   a. print " overflow"
   b. exit
2. top A = top A + 1
3. A[top A] = x
4. stop
```

Algorithm for pop A(x)

```
1. if (top A = - 1)
   a. print "underflow"
   b. exit
2. y = A[top A]
3. top A = top A - 1
4. return y
5. stop
```

Algorithm for push B(x)

```
1. if (top B - 1 = top A)
   a. print "overflow"
   b. exit
2. top B = top B -1
3. A[top B] = x
4. stop
```

Algorithm for pop B(x)

```
1. if (top B = max)
   a. print "underflow"
   b. exit
2. y = A [top B]
3. top B = top B - 1
4. return y
5. stop
```

QUEUE

A queue is an ordered collection of items from which items may be deleted at one end (called that front of queue) and into which items may be inserted at the other end (called rear of queue).

Queue is a linear data structure maintains the data in first in–first out (FIFO) order.

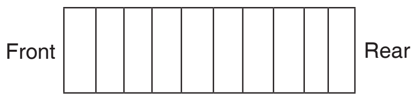
Implementation

Queue can be implemented in the following ways:

1. Array static implementation: queue cannot be extended beyond the array size.
2. Linked list dynamic implementation: Queue size increases as the elements added/inserted to queue. Queue shrinks when an element deleted from queue.

Array Implementation

const int SIZE = 10;
int *q*[SIZE];
int $f = -1$, $r = -1$; //$f = r = -1$ represents queue empty



Insertion

```
1. void insert (int x)
2. {
3. if (r = = SIZE -1)
4. {
5. printf("Q FULL")
6. return;
7. }
8. r++;
9. q[r] = x;
10. if (f = = -1)
11. f = r;
12. }
```

Step 3 – Checks for queue full
Step 8 – Increments rear (*r*)
Step 9 – Inserts '*x*' into queue
Step 10 – Checks whether insertion is first
Step 11 – If first insertion, updates front (*f*)

Deletion

```
1. void deletion()
2. {
3. int x;
4. if (f = = -1)
5. {
6. if ("\n Q Empty");
7. return;
8. }
9. x = q[f];
10. if (f = = r)
11. f = r = -1;
12. else
13. f++;
14. printf("\n deleted element %d", x);
15. }
```

Step 4 – Checks for queue empty
Step 9 – Deletes '*q*' front element
Step 10 – Checks whether queue having only one element
Step 11 – Rear and front initializes to –1, if queue is having only one element
Step 13 – Queue front points to next element
Step 14 – Deleted element is printed

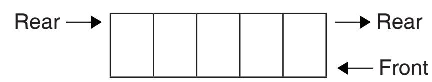
Display

```
1. void display( )
2. {
3. int i = f;
4. if (f = = -1)
5. {
6. printf("Queue Empty");
7. return;
8. }
9. printf ("\n Queue Elemetns");
10. for(; i < = r; i++)
11. printf(" %d", q[i]);
12. }
```

Step 4 – Checks for '*q*' empty
Step 10 and 11 – Display '*q*' elements

Double-ended Queue

A double-ended queue (deque) is an abstract data structure that implements a queue for which elements can only be added to or removed from the front (head) (or) rear (tail) end.



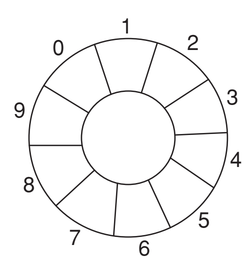
Insertions and deletions are possible at both ends.

Linked List Implementation Double-ended Queue

- Insert – Front is same as insert – Head
- Insert – Rear is same as insert – Tail
- Delete front is same as delete – Head
- Delete – Rear is same as delete – Tail

Circular Queue

As the items from a queue get deleted, the space for that item is reclaimed. Those queue positions continue to be empty. This problem is solved by circular queues. Instead of using a linear approach, a circular queue takes a circular approach; this is why a circular queue does not have a beginning or end.



The advantage of using circular queue over linear queue is efficient usage of memory.

Algorithm to implement addition and deletion from circular queue

Circular Queue Insertion:
To add an element '*X*' to a Queue '*Q*' of size '*N*' with front and rear pointers as '*F*' and '*R*' is done with insert (*X*), Initially $F = R = 0$.
Insert (*X*)

Steps:

```
1. if (((R = N ) & & (F = 1)) or ((R +
   1) = F))
   a. print "overflow"
   b. exit
2. if (R = N)
   then R = 0;
   Else
      R = R + 1;
3. Q[R] = x;
4. if (F = 0)
   F = 1
5. Stop.
```

To delete an element we implement an algorithm delete (). '*y*' contains the deleted element.

delete()

Steps:

```
1. if (F = 0)
   a. print "underflow"
   b. exit
2. y = Q[F]
3. if (F = R)
   F = R = 0
   else
   If (F = N)
   F = 1
   Else
   F = F + 1
4. Return y
5. Stop.
```

Priority Queue

In priority queue, the intrinsic ordering of elements does determine the results of its basic operations.

There are two types of priority queues.

- Ascending priority queue is a collection of items in which items can be inserted arbitrarily and from which only the smallest items can be removed.
- Descending priority queue is similar but allows deletion of the largest item.

Array Implementation

- The insertion operation on priority queue selects the position to the element to insert.
- Makes the position empty/free by moving the existing element (if required).
- Place the element in required position.
- Deletion operation simply deletes front of queue.

Linked-list Implementation

- Insertion operation create a node
- Reads element into node
- Find out the location
- Insert the node into list, by adjusting the reference
- Deletion operation simply deletes head elements, making the head next as head element

Linked-list Implementation of Priority Queue

- Insertion in queue is same as insert-tail of queue
- Deletion from queue is same as delete head

Exercises

Practice Problems I

Directions for questions 1 to 16: Select the correct alternative from the given choices.

1. If the array representation of a circular queue contains only one element then

(A) front = rear (B) front = rear + 1
(C) front = rear − 1 (D) front = rear = NULL

2. The five items *P*, *Q*, *R*, *S* and *T* are pushed in a stack, one after another starting from *P*. The stack is popped four times, and each element is inserted in a queue. The two elements are deleted from the queue and pushed back on the stack. Now one item is popped from the stack. The popped item is ______.

(A) *P* (B) *Q*
(C) *R* (D) *S*

3. What are the contents of the stack (initially the stack is empty) after the following operations?

PUSH (A)
PUSH (B)
PUSH (C)
POP
PUSH(D); POP; POP;
PUSH(E)
PUSH(F)
POP

(A) ABE (B) AE
(C) A (D) ABCE

4. Consider the below code, which deletes a node from the beginning of a list:

```
void deletefront()
{
if(head == NULL)
return;
else
{
..........
.........
.........
}
}
```

Which lines will correctly implement else part of above code?

(A) `if (head → next = = NULL)`
    `head = head → next;`
(B) `if (head = = tail)`
    `head = tail = NULL;`
    `else`
    `head = head → next;`
(C) `if (head = = tail = = NULL)`
    `head = head → next;`
(D) `head = head → next;`

5. When a new element is inserted in the middle of linked list, then the references of _____ to be adjusted/updated.
(A) those nodes that appear after the new node
(B) those nodes that appear before the new node
(C) head and tail nodes
(D) those nodes that appear just before and after the new node

6. The following C function takes double-linked list as an argument. It modifies the list by moving the head (first) element to tail of the list.

```
typedef struct node
{
    struct node *p;
    int data;
    struct node *n;
} Node;
Node * Move - to - last (Node *head)
{
Node * temp, * prev, * next;
if (head = = NULL)||(head → n = = NULL))
return head;
temp = head;
prev = head;
head = head → n;
while (prev → n! = NULL)
{
X;
}
Y;
return head;
}
```

(A)
```
X: prev = prev → n;
Y: prev → n = temp;
temp → p = prev;
temp → n = NULL;
head → P = NULL;
```
(B)
```
X: next = prev → n;
Y: prev → n = temp;
temp → p = prev;
```
(C)
```
X: prev = prev → n;
Y: prev → n = temp;
temp → n = NULL;
head → p = NULL;
```
(D)
```
X: next = prev → n;
prev = prev → n;
Y: prev → n = Next;
next → n = head;
temp → n = NULL;
```

7. Which of the following program segment correctly inserts an element at the front of the linked list. Assume that Node represents linked list node structure, value is the element to be inserted.

(A)
```
temp = (Node *)malloc (sizeof (Node));
temp → data = value;
temp → next = head;
head = temp;
```
(B)
```
temp = (Node *)malloc(sizeof (Node*)
);
temp → data = value;
temp → next = head;
head = temp;
```
(C)
```
temp = (Node *)malloc (sizeof (Node));
head = temp;
temp → next = head;
temp → data = value;
```
(D)
```
temp = (Node *)malloc (sizeof (Node
*);
temp → data = value;
head = temp;
temp → next = head;
```

8. Consider the following program segment:

```
struct element
{
    int x;
    struct element *link;
}
void shuffle(struct element *head)
{
struct *p, *q;
int t;
if (!head || !head → link) return;
p= head ; q = head → link;
while(q)
{
t = p → x;
p→ x = q → x;
q → x = t;
p = q → link;
q = p?  p : 0;
}
}
```

The function called with list containing 10, 15, 20, 25, 30, 35, 40 in given order. What will the order of elements of the list, after executing the function shuffle?

(A)	10	15	20	25	30	35	40
(B)	40	35	30	25	20	15	10
(C)	20	15	10	25	40	35	30
(D)	15	10	25	20	35	30	40

9. Primary ADT's are
(A) Linked list only
(B) Stack only
(C) Queue only
(D) All of these

10. Linked list uses NULL pointers to signal
(A) end of list (B) start of list
(C) Either (A) or (B) (D) Neither (A) nor (B)

11. Which of the following is essential for converting an infix to postfix form efficiently?
(A) Operator stack (B) Operand stack
(C) Both (A) and (B) (D) Parse tree

12. Stacks cannot be used to
(A) Evaluate postfix expression
(B) Implement recursion
(C) Convert infix to postfix
(D) Allocate resource like CPU by the operating system

13. Linked list can be sorted
(A) By swapping data only
(B) By swapping address only
(C) Both (A) and (B)
(D) None of these

14. Linked list are not suitable for implementing
(A) Insertion sort
(B) Binary search
(C) Radix sort
(D) Polynomial manipulation

15. Insertion of node in a double-linked list requires how many changes to previous (prev) and next pointers?
(A) No changes (B) 2 next and 2 prev
(C) 1 next and 1 prev (D) 3 next and 3 prev

16. Minimum number of stacks required to implement a queue is
(A) 1 (B) 2
(C) 3 (D) 4

Practice Problems 2

Directions for questions 1 to 11: Select the correct alternative from the given choices.

1. Stack is useful for implementing _____.
(A) radix sort
(B) breadth first search
(C) quick sort
(D) recursion

2. Which is true about linked list?
(A) A linked list is a dynamic data structure.
(B) A linked list is a static structure.
(C) A stack cannot be implemented by a linear linked list.
(D) None of the above

3. The process of accessing the data stored in a tape is similar to manipulating data on a _____.
(A) stack (B) list
(C) queue (D) heap

4. Which of the following is used to aid in evaluating a prefix expression?
(A) Queue (B) Heap
(C) Stack (D) Hash

5. Select the statement which best completes the sentence — 'Abstract data type is…'
(A) a data type which is abstract in nature
(B) a kind of data type
(C) data structure
(D) a mathematical model together with a set of operations defined on it

6. Which of the following data structures may give an overflow error, even through the current number of elements in it is less than its size?
(A) Simple queue (B) Circular queue
(C) Stack (D) None of these

7. In a circular linked list, insertion of a record involves the modification of _____.
(A) no pointer (B) four pointers
(C) two pointers (D) All of the above

8. Among the following, which one is not the right operation on a stack?
(A) Remove the item that is inserted latest into the stack.
(B) Add an item to the stack.
(C) Remove the first item that is inserted into the stack, without deleting other elements.
(D) None of the above

9. Among the following which one is not the right operation on dequeue?
(A) Inserting an element in the middle of a dequeue.
(B) Inserting an element at the front of a dequeue.
(C) Inserting an element at the rear of a dequeue.
(D) None of the above

10. A linear list in which elements can be added or removed at either end but not in the middle is _____.
(A) queue
(B) dequeue
(C) array
(D) tree

11. The post fix notation of $A/B * * C + D * E - A * C$ is
(A) $ABC * * /DE * + AC * -$
(B) $ABC * * D/E * + AC + -$
(C) $ABC * * /DE * AC + -$
(D) $ABC * * /DE * + AC + -$

Previous Years' Questions

1. An abstract data type (ADT) is **[2005]**
(A) same as an abstract class.
(B) a data type that cannot be instantiated.
(C) a data type for which only the operations defined on it can be used, but none else.
(D) All of the above

2. An implementation of a queue Q, using two stacks S_1 and S_2, is given below:

```
void insert (Q, x)   {
  push (S1, x);
}
void delete (Q)   {
  if (stack-empty (S2)) then
    if (stack-empty (S1)) then    {
      print ("Q is empty");
      return;
    }
    else while(!(stack-empty(S1)))
    {
        x = pop (S1);
        push(S2, x);
    }
  x = pop (S2);
}
```

Let n insert and m (″ n) delete operations be performed in an arbitrary order on an empty queue Q. Let x and y be the number of push and pop operations performed respectively in the process. Which one of the following is true for all m and n? **[2006]**
(A) $n + m$ ″ $x < 2n$ and $2m$ ″ y $n + m$
(B) $n + m$ ″ $x < 2n$ and $2m$ ″ y $2n$
(C) $2m$ ″ $x < 2n$ and $2m$ ″ y $n + m$
(D) $2m$ ″ $x < 2n$ and $2m$ ″ y $2n$

3. The following postfix expression with single digit operands is evaluated using a stack:
8 2 3 ∧ / 2 3 ∗ + 5 1 ∗ −
Note that ∧ is the exponentiation operator. The top two elements of the stack after the first ∗ is evaluated are: **[2007]**
(A) 6 and 1 (B) 5 and 7
(C) 3 and 2 (D) 1 and 5

4. The following C function takes a single-linked list of integers as a parameter and rearranges the elements of the list. The function is called with the list containing the integers 1, 2, 3, 4, 5, 6, 7 in the given order. What will be the contents of the list after the function completes execution?

```
struct node {
int value;
struct node *next;
};
void rearrange (struct node *list) {
struct node *p, *q;
int temp;
if (!list || !list -> next) return;
p = list; q = list -> next;
while (q) {
temp = p -> value; p -> value = q ->
value;
    q -> value = temp; p = q → next;
    q = p?p -> next : 0;
}
}
```

[2008]
(A) 1, 2, 3, 4, 5, 6, 7 (B) 2, 1, 4, 3, 6, 5, 7
(C) 1, 3, 2, 5, 4, 7, 6 (D) 2, 3, 4, 5, 6, 7, 1

5. Suppose a circular queue of capacity $(n - 1)$ elements is implemented with an array of n elements. Assume that the insertion and deletion operations are carried out using REAR and FRONT as array index variables, respectively. Initially, REAR = FRONT = 0. The conditions to detect queue full and queue empty are **[2012]**
(A) Full: (REAR + 1) mod n = = FRONT
Empty: REAR = = FRONT
(B) Full: (REAR + 1) mod n = = FRONT
Empty: (FRONT + 1) mod n = = REAR
(C) Full: REAR = = FRONT
Empty: (REAR + 1) mod n = = FRONT
(D) Full: (FRONT + 1) mod n = = REAR
Empty: REAR = = FRONT

6. Consider the C program below **[2015]**

```
#include <stdio.h>
int *A, stkTop;
int stkFunc (int opcode, int val)
{
  static int size=0, stkTop=0;
  switch (opcode) {
    case -1: size = val; break;
    case 0: if (stkTop < size)
  A[stkTop++] =
       val; break;
    default: if (stkTop) return A[-
    -stkTop];
  }
  return -1;
}
   int main ( )
   {
   int B[20]; A = B; stkTop = -1;
   stkFunc (-1, 10);
   stkFunc (0, 5);
   stkFunc (0, 10);
   printf ("%d\n", stkFunc(1, 0) +
   stkFunc(1, 0));
   }
```

The value printed by the above program is _____

7. The result of evaluating the postfix expression 10 5 + 60 6/* 8 – is **[2015]**
(A) 284 (B) 213
(C) 142 (D) 71

8. Let *Q* denote a queue containing sixteen numbers and *S* be an empty stack.

Head (*Q*) returns the element at the head of the queue **Q without** removing it from **Q**. Similarly Top(*S*) returns the element at the top of **S without** removing it from *S*.

Consider the algorithm given below.

```
while Q is not Empty do
        if S is Empty OR Top(S) ≤ Head (Q)
        then
                x : = Dequeue (Q)
                Push (S, x);
        else
                x : = Pop (S);
                enqueue (Q, x);
        end
end
```

The maximum possible number of iterations of the while loop in the algorithm is ____ . **[2016]**

9. The attributes of three arithmetic operators in some programming language are given below.

Operator	Precedence	Associativity	Arity
+	High	Left	Binary
–	Medium	Right	Binary
*	Low	Left	Binary

The value of the expression

2 – 5 + 1 – 7 * 3 in this language is ______. **[2016]**

10. A circular queue has been implemented using a singly linked list where each node consists of a value and a single pointer pointing to the next node. We maintain exactly two external pointers **FRONT** and **REAR** pointing to the front node and the rear node of the queue, respectively. Which of the following statements is/are CORRECT for such a circular queue, so that insertion and deletion operations can be performed in O (1) time?

I. Next pointer of front node points to the rear node.
II. Next pointer of rear node points to the front node.

[2017]

(A) I only (B) II only
(C) Both I and II (D) Neither I nor II

Trees

LEARNING OBJECTIVES

- *Tree*
- *2-Tree*
- *Binary tree*
- *Properties of binary trees*
- *Complete binary tree*
- *Full binary tree*
- *Binary tree representation*
- *Linked representation*
- *Binary search tree*
- *Binary tree traversing methods*
- *AVL tree*
- *Binary heap*
- *Max-heap*
- *Min-heap*
- *Expression tree*

Tree

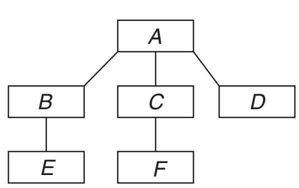
Tree is non-linear data structure designated at a special node called root and elements are arranged in levels without containing cycles.

(or)

The tree is

1. Rooted at one vertex
2. Contains no cycles
3. There is a sequence of edges from any vertex to any other
4. Any number of elements may connect to any node (including root)
5. A unique path traverses from root to any node of tree
6. Tree stores data in hierarchical manner
7. The elements are arranged in layers

Example:



- Root node is A.
- A's children are B, C and D.
- E, F and D are leaves.
- Nodes B, C are called as intermediate nodes.
- A is parent of B, C and D.
- B is parent of E and C is parent of F.
- Number of children of a node is called degree of node.

2-Tree

A tree in which every node contains either 0 or 2 children.

Binary Tree

It is a special type of tree where each node of tree contains either 0 or 1 or 2 children.

(or)

Binary Tree is either empty, or it consists of a root with two binary trees called left-sub tree and right sub-tree of root (left or right or both the sub trees may be empty).

Properties of binary tree

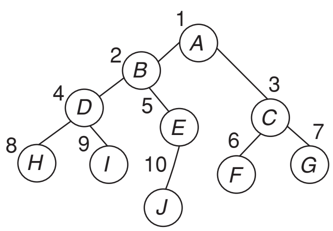
- Binary tree partitioned into three parts.
- First subset contains root of tree.
- Second subset is called left subtree.
- Another subset is called right subtree.
- Each subtree is a binary tree.
- Degree of any node is 0/1/2.
- The maximum number of nodes in a tree with height 'h' is $2^{h+1}-1$.
- The maximum number of nodes at level 'i' is 2^{i-1}.
- For any non-empty binary tree, the number of terminal nodes with n_2, nodes of degree 2 is $N_0 = n_2 + 1$
- The maximum number of nodes in a tree with depth d is $2^d - 1$.

Types of binary tree

Complete binary tree It is a binary tree, in which at every level, except possibly the last, is completely filled and all nodes at the last level are as left as possible.

Example:

Level	Height	Depth
1	3	1
2	2	2
3	1	3
4	0	4



For the given tree:

- Having 4 levels
- Height of the tree is 3
- Depth of the tree is 4
- The numbers at each node represents level order index.
- The level order Index, are assigned to nodes in the following manner
- Root of the tree is '1'
- For a node 'x', the LOI is (2 * LOI (parent)), if 'x' is left child of its parent.
- For a node 'y', the LOI (2 * LOI (Parent) +1), if 'y' is right child of its parent.

Now complete binary tree can be defined as a binary tree, which contains a sequence of numbers to its nodes as LOI's without any break in sequence.

Full binary tree It is a binary tree, for which all leaf nodes are at same level and all intermediate nodes contains exactly 2 children.

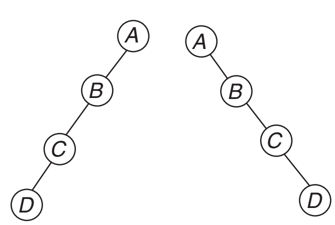
(or)

A tree with depth 'K' contains exactly $2^K - 1$ nodes.

Strictly binary tree A binary tree in which every node contains exactly 0 or 2 children.

Skewed binary tree A binary tree in which elements are added only in one direction.

Example:



Left-skewed Right-skewed

Application

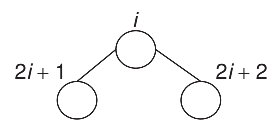
- A binary tree is useful data structure when two way decisions must be made at each point of process.

Binary tree representation

The binary trees can be represented in two ways.

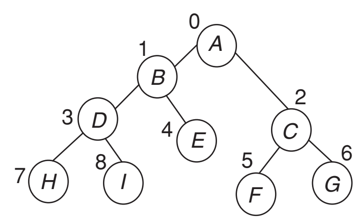
- Array
- Linked list

Array representation The elements of a binary tree are placed in an array using the level order index of each element.



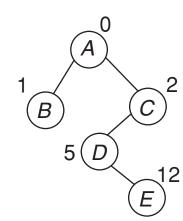
When LOI of Root is 0:

Example 1:



0	1	2	3	4	5	6	7	8
A	*B*	*C*	*D*	*E*	*F*	*G*	*H*	*I*

Example 2:

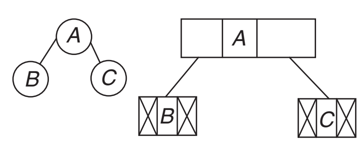


0	1	2	3	4	5	6	7	8	9	10	11	12
A	*B*	*C*			*D*							*E*

Linked representation Each node contains one data field and two link fields. Fist link point to the left child and another point to the right child.

In absence of any child, corresponding link field contains NULL.

Example:



Trade-off's between array and linked, representations

- Array representation is somewhat simpler. It must ensure elements are placed in array at proper position.
- Linked representation requires pointer to its left and right child.
- Array representation saves memory for almost complete binary trees.
- Linked representation allocates the number and nodes equal to the number of elements in tree.
- Array representation does not work efficiently for skewed binary trees.
- Array representation limits the size of binary tree to the array size.
- In linked representation, tree can be extended by adding an element dynamically and can be shrinked by deleting an element dynamically.

Binary search tree

It is a special type of binary tree that satisfies the following properties.

- All the elements of left sub tree of root are smaller than root.
- All the elements of right sub tree of root are greater than root.
- The above two properties satisfy for each subtree.

Example:

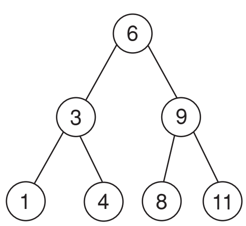


Figure 1 A data structure to encode binary search tree

The binary search tree node contains three fields, data field, left child, right child. Left child is a pointer which points to the predecessor of the node and right child is a pointer which points to the successor of the node.

A data structure to encode binary search tree is

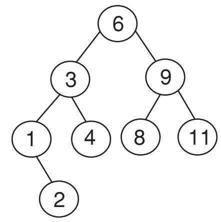
Left child	Data	Right child

The declaration is

```
Struct node
{
Struct node * left child;
Int data;
Struct node * Right child;
};
```

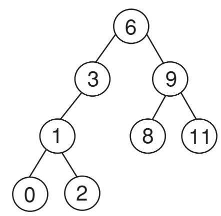
Insertion If a value to be inserted is smaller than the root, value, it must go in the left subtree, if larger it must go in the right subtree. This reasoning applies recursively until we reach a node where the required subtree does not exist and that is where we place the new value.

Example: It must go in 6's left subtree, 3's left subtree, 1's right subtree, 1 has no right subtree, so we make a singleton with 2 and it becomes 1's right subtree.

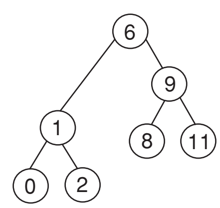


Deletion:

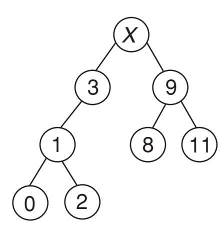
1. If a leaf node has to be deleted, just delete it and the rest of the tree is exactly as it was, so it is still a BST.
2. Suppose the node we are deleting has only one sub tree
   Example, In the following tree, '3' has only one sub-tree



To delete a node with 1 subtree, we just 'link past' the node, i.e., connect the parent of the node directly to the node's only subtree. This always works, whether the one subtree is on the left or on the right. Deleting 3 gives us.



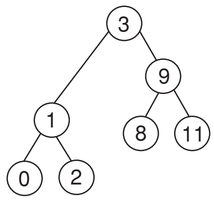
3. Deletion of node which has 2 subtrees
   Example: Delete 6.



Choose value '*X*'

1. Everything in the left subtree must be smaller than *X*.
2. Everything in the right subtree must be bigger than *X*.

We must choose X to be the largest value in the left subtree. In our example, 3 is the largest value in the left subtree. So we replace root node 6 with 3.



Note: We could do the same thing with the right subtree. Just use the smallest value in the right subtree.

Notes:

- The largest element in left subtree is the right most element.
- The smallest element in right subtree is the left most element.

Binary tree traversing methods

The binary tree contains 3 parts:

V – root

L – Left subtree

R – Right subtree

Pre-order: (*V*, *L*, *R*)

- Visit root of the tree first
- Traverse the left - subtree in pre-order
- Traverse the right - subtree in preorder

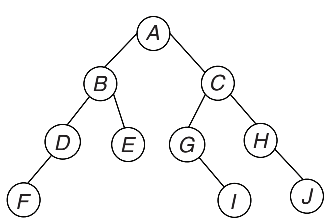
In-order: (*L*, *V*, *R*)

- Traverse the left – subtree in in-order
- Visit Root of the tree
- Traverse right - sub tree in in-order

Post-order: (*L*, *R*, *V*)

- Traverse the left subtree in post-order.
- Traverse the Right - subtree in post-order
- Visit root of the tree

Example 1:



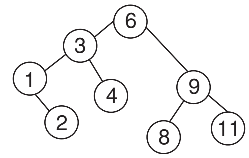
Pre-order: *A B D F E C G I H J*

In-order: *F D B E A G I C H J*

Post-order: *F D E B I G J H C A*

Pre-order, In-order and post-order uniquely identify the tree.

Example 2:



Pre-order:	6 3 1 2 4 9 8 11
In-order:	1 2 3 4 6 8 9 11
Post-order:	2 1 4 3 8 11 9 6

Points to remember

- Pre-order traversal contains root element as first element in traverse list.
- Post-order traversal contains root element as last in traversal list.
- For BST, in-order traversal is a sorted list.
- A unique binary tree can constructed if either pre-order or post-order traversal list provided with In order traversal list.
- If either pre-order or post-order only given then BST cannot be constructed.

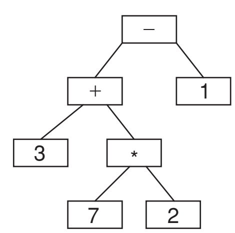
Applications

1. Binary trees can represent arithmetic expressions.
   - An infix expression will have a parent operator and two children operands.

Consider the expression $((3 + (7 * 2)) - 1)$

Each parenthesised expression becomes a tree.

Each operand is a leaf, each operator is an internal node.

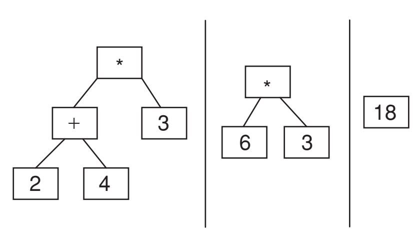


2. To evaluate the expression tree:

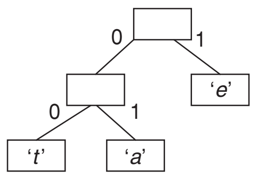
   Take any two leaves

   Apply the parents operator to them

   Replace the operator with the value of the sub expression.



3. Binary trees in a famous file compression algorithm Huffman coding tree
    - Each character is stored in a leaf
    - The code is found by following the path 0 go left, 1 go right.
    - *a* is 01
    - *e* is 1



AVL Tree

An AVL tree is a self-balancing binary search tree, in which the heights of the two child subtrees of any node differ by atmost one.

Insertions and deletions may require the tree to be rebalanced by one or more tree rotations.

- The balance factor of a node is the height of its left subtree minus the height of its right subtree (sometimes opposite) and a node with balance factor—1, 0 or −1 is considered balanced. A node with any other balance factor is considered unbalanced and requires rebalancing the tree.
- The balance factor is either stored directly at each node or computed from the heights of the subtrees.

Insert operations

Step I: Insert a node into the AVL tree as it is inserted in a BST.

Step II: Examine the search path to see if there is a pivot node.

Three cases may arise

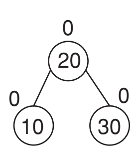
Case I: There is no pivot node. No adjustment required.

Case II: The pivot node exists and the subtree of the pivot node to which the new node is added has smaller height. No adjustment required.

Case III: The pivot node exists and the subtree to which the new node is added has the larger height, Adjustment required.

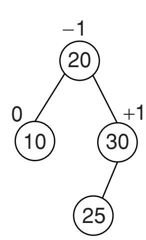
Example: The numbers at each node represents balance factor.

Example 1:



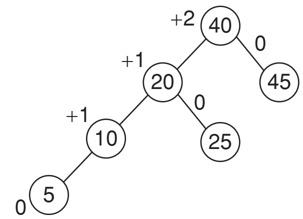
AVL tree

Example 2:



AVL tree

Example 3:



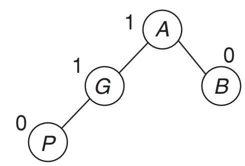
Not an AVL tree

Example 3 is not an AVL tree, because the balance factor of root node is +2.

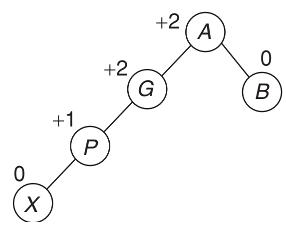
AVL tree becomes height in-balanced tree in following cases:

1. Left-Left case: An insertion in left subtree of left child of pivot node.

Example:

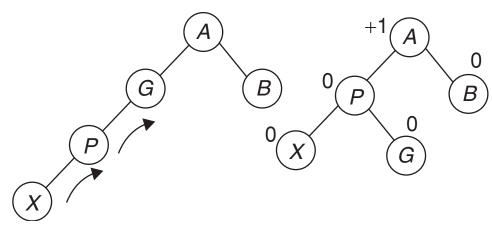


Insert '*X*' as left to node '*P*'. Here '*G*' is pivot node.



Solution:

To make the tree as balanced tree, perform **Left–Left Rotation** as follows:

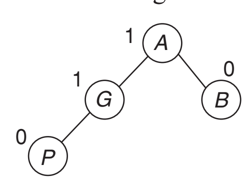


In left–left rotation

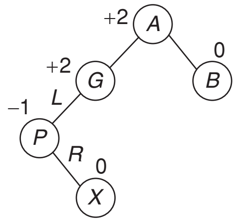
- Intermediate node '*P*' becomes root of subtree.
- Root of subtree '*G*' (pivot) becomes right subtree.
- New node '*X*' remains same as left child of '*P*'.

Left–Right Case

An insertion of left subtree of right child of pivot node.

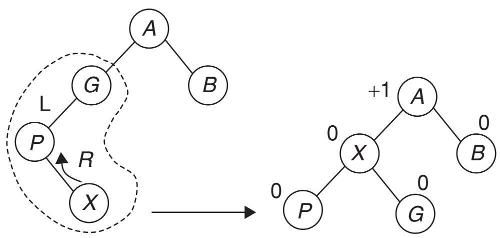


Example 1: Insert '*X*' as right child of '*P*'.



Is not an AVL tree. Height in-balance at node '*G*'.

Solution:
Perform Left–Right Rotation, to balance the height of tree.



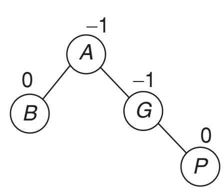
In Left–Right rotation:

- New node '*X*' becomes root of subtree.
- Root of subtree '*G*' (pivot) becomes right child of '*X*'.
- Intermediate node '*P*' becomes left child of new node.

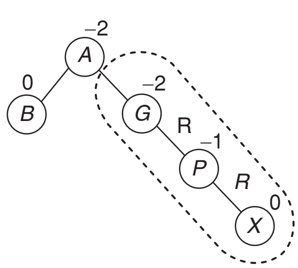
Right–Right case

An insertion of right subtree of right child of pivot node.

Example:

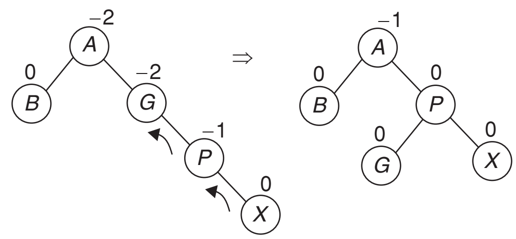


Insert '*X*' as right child of '*P*'



Is not an AVL tree, because of height in-balance at node '*G*'.

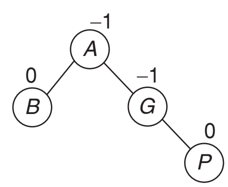
Solution:
To make the tree as balanced tree, perform the right–right rotation as follows:



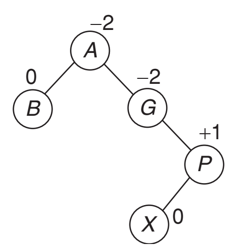
In Right–Right rotation:

- Intermediate node '*P*' becomes root of subtree.
- Root of subtree '*G*' (pivot) becomes left child of '*P*'.
- New node '*X*' remains as right child to '*P*'.

Right–Left case
An insertion of right subtree of left child of pivot node.

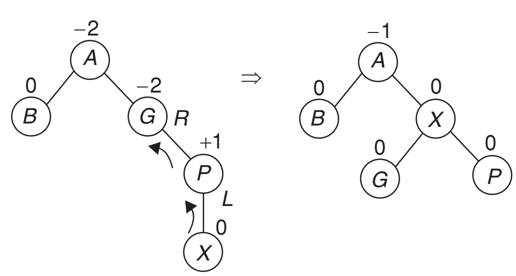


Insert '*X*' as left child of '*P*'



Is not AVL tree, because height in-balance at node '*G*'.

Solution:
To make the above tree as balanced, perform Right–Left rotation as follows:



In Right–Left Rotation:

- New node '*X*' becomes root of subtree.
- Root of subtree '*G*' (pivot) becomes left child of '*X*'.
- Intermediate node '*P*' becomes right of '*X*'.

Note: Left–Right and Right–Left rotation are also called as double rotations.

BINARY HEAP

A binary heap is a heap data structure created using a binary tree. It can be seen as a binary tree with two additional constraints.

The shape property: The tree is a complete binary tree; that is, all levels of the tree, except possibly the last one (deepest) level of the tree is not complete, the nodes of that level are filled, from left to right.

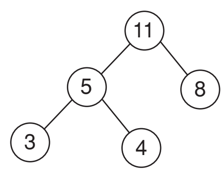
Max-Heap

A heap in which each node is greater than or equal to its children is called max-heap. Max-Heap generally used for heap sort.

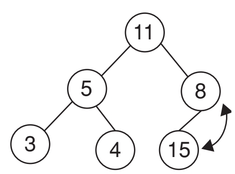
Min-Heap

A heap in which, each node is smaller than or equal to its children is called Min-Heap. Min-heap generally used to implement priority queue.

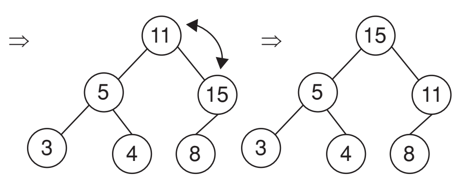
Note: By default heap represent Max-Heap:



Insert 15:

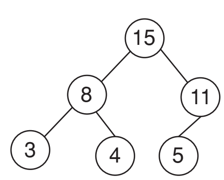


Is not satisfying heap property. So Heapify

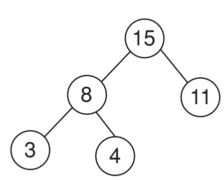


Delete 5: Deletion of a node from heap is always deletes a leaf node.

So interchange the value of last leaf node with node 5.



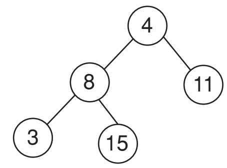
Now delete node '5'



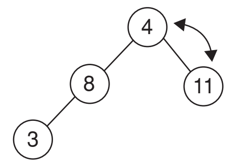
Is satisfying heap property.

Delete 15:

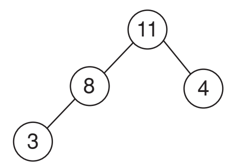
Interchange 4 and 15



Now delete Node '15'



Is not satisfying heap property. So heapify



Note: Insertion or deletion operation on a heap may require heapify process.

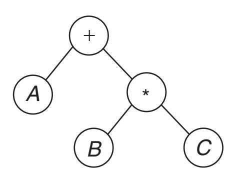
Expression Tree

The expressions can also represented by using a binary tree called expression tree.

Expression tree contains:

- Operators as intermediate nodes.
- Operands as leaf nodes (or) childs to operator nodes.
- The operator at lowest level will be having highest priority.

Example: $A + B * C$



Traversing:

Pre-order: $+ A * B C$

In-order: $A + B * C$

Post-order: $A B C * +$

Note: In-order traversal of expression tree generates In-fix expression. Similarly pre-order and post-order generates prefix and postfix, respectively.

Exercises

Practice Problems 1

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. A binary tree T has n leaf nodes. The number of nodes of degree two in T is ____.
   (A) n (B) $n - 1$
   (C) $\log n$ (D) $n + 1$
2. How many numbers of binary tree can be created with 3 nodes which when traversed in post-order gives the sequence C, B, A?
   (A) 3 (B) 5
   (C) 8 (D) 15
3. A binary search tree contains the values 3, 6, 10, 22, 25, 30, 60, 75. The tree is traversed in pre-order and the values are printed out. Which of the following sequence is a valid output?
   (A) 25 6 3 10 22 60 30 75
   (B) 25 6 10 3 22 75 30 60
   (C) 25 6 75 60 30 3 10 22
   (D) 75 30 60 22 10 3 6 25
4. Figure shows a balanced tree. How many nodes will become unbalanced when a node is inserted as a child of the node 'g'?

   (A) 7 (B) 2
   (C) 3 (D) 8
5. A full binary tree with n non-leaf nodes contains
   (A) $2n$ nodes (B) $\log_2 n$ node
   (C) $n + 1$ nodes (D) $2n + 1$ nodes
6. Which of the following list of nodes corresponds to a post order traversal of the binary tree shown below?

   (A) *A B C D E F G H I J* (B) *J I H G F E D C B A*
   (C) *D H E B I F J G C A* (D) *D E H F I G J B C A*
7. Which of the following sequence of array elements forms as heap?
   (A) {23, 17, 14, 6, 13, 10, 1, 12, 7, 5}
   (B) {23, 17, 14, 6, 13, 10, 1, 5, 7, 12}
   (C) {23, 17, 14, 7, 13, 10, 1, 5, 6, 12}
   (D) {23, 17, 14, 7, 13, 10, 1, 12, 5, 6}
8. What is the maximum height of any AVL tree with 7 nodes? Assume that the height of a tree with a single node is 0.
   (A) 2 (B) 3
   (C) 4 (D) 5
9. A binary search tree is generated by inserting in order the following integers:
   55, 15, 65, 5, 25, 59, 90, 2, 7, 35, 60, 23.
   The number of nodes in the left subtree and right subtree of the root respectively are
   (A) 8, 3 (B) 7, 4
   (C) 3, 8 (D) 4, 7
10. In a complete binary tree of n nodes, how far are the most distant two nodes? Assume each in the path counts as 1.
    (A) about $\log_2 n$ (B) about $2\log_2 n$
    (C) about $3\log_2 n$ (D) about $4\log_2 (n)$
11. A complete binary tree of level 5 has how many nodes?
    (A) 20 (B) 63
    (C) 30 (D) 73

Common data for questions 12 and 13: A 3-ary max-heap is like a binary max-heap, but instead of 2 children, nodes have 3 children. A 3-ary heap can be represented by an array as follows:

The root is stored in the first location, $a[0]$, nodes in the next level from left to right is stored from $a[1]$ to $a[3]$ and so on. An item x can be inserted into a 3-ary heap containing n items by placing x in the location $a[n]$ and pushing it up the tree to satisfy the heap property.

12. Which one of the following is a valid sequence of elements in an array representing 3-ary max-heap?
    (A) 1, 3, 5, 6, 8, 9 (B) 9, 6, 3, 1, 8 , 5
    (C) 9, 3, 6, 8, 5, 1 (D) 9, 5, 6, 8, 3, 1
13. Suppose the elements 7, 2, 10 and 4 are inserted, in that order, into the valid 3-ary max-heap found in the above question. Which one of the following is the sequence of items in the array representing the resultant heap?
    (A) 10, 7, 9, 8, 3, 1, 5, 2, 6, 4
    (B) 10, 9, 8, 7, 6, 5, 4, 3, 2, 1
    (C) 10, 9, 4, 5, 7, 6, 8, 2, 1, 3
    (D) 10, 8, 6, 9, 7, 2, 3, 4, 1, 5
14. Consider the nested representation of binary trees : (X Y Z) indicated Y and Z are the left and right subtrees respectively, of node X(Y and Z may be null (or) further nested) which of the following represents a valid binary tree?

(A) (1 2 (4 5 6 7)) (B) (1(2 3 4)5 6)7
(C) (1(2 3 4) (5 6 7)) (D) (1(2 3 NULL)(4 5))

15. A scheme for storing binary trees in an array X is as follows:

Indexing of X starts at 1 instead of 0. The root is stored at $X[\ 1\ ]$. For a node stored at $X[i]$, the left child, if any, is stored in $X[\ 2i\ ]$ and the right child, if any, in $X[2i + 1]$. To store any binary tree on 'n' vertices the minimum size of X should be

(A) $2n$ (B) n
(C) $3n$ (D) n^2

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. A binary search tree contains the values 1, 2, 3, 4, 5, 6, 7, 8. The tree is traversed in pre-order and the values are printed out. Which of the following is a valid output?
(A) 53124786 (B) 53126487
(C) 53241678 (D) 53124768

2. A binary search tree is generated by inserting in order the following integers : 50, 15, 62, 5, 20, 58, 91, 3, 8, 37, 60, 24. The number of nodes in the left subtree and right subtree of the root respectively are:
(A) (4, 7) (B) (7, 4)
(C) (8, 3) (D) (3, 8)

3. A full binary tree (with root at level 0) of height h has a total number of nodes equal to:
(A) 2^h (B) $2^{h+1} - 1$
(C) $2^h - 1$ (D) 2^{h-1}

4. The number of null pointers of a binary tree of n nodes is :
(A) $n + 1$ (B) $n(n + 1)$
(C) n^2 (D) $2n$

5. Which of the following is false?
(A) A tree with n nodes has $(n - 1)$ edges.
(B) A labeled rooted binary tree can be uniquely constructed, given its post-order, in-order traversal results.
(C) The complete binary tree with n internal nodes has $(n + 1)$ leaves.
(D) The maximum number of nodes in a binary tree of height h is $(2^{h+1} - 1)$.

6. The maximum number of nodes in a binary tree at level i is
(A) 2^i (B) $2^i - 1$
(C) $2^i + 1$ (D) $\log_2 i + 1$

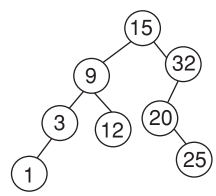
7. The number of leaf nodes in a rooted tree of n nodes, with each node having 0 or 3 children is
(A) $\frac{n}{3}$ (B) $\frac{(n-1)}{3}$
(C) $\frac{(n-1)}{2}$ (D) $\frac{(2n+1)}{3}$

8. A complete n-ary tree is one in which every node has 0 or n children. If x is the number of internal nodes of a complete n-ary tree, the number of leaves in it is given by
(A) $x(n - 1) + 1$
(B) $xn + 1$
(C) $xn - 1$
(D) $x(n + 1) - 1$

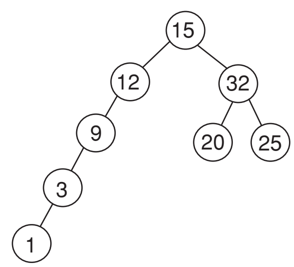
Common data for questions 9 and 10:

9. Insert the keys into a binary search tree in the order specified 15, 32, 20, 9, 3, 25, 12, 1. Which one of the following is the binary search tree after insertion of all elements?

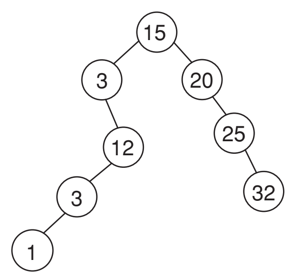
(A)



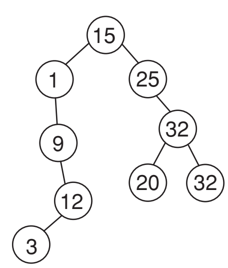
(B)



(C)

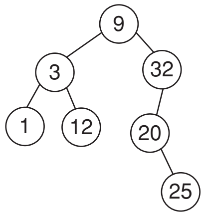


(D)

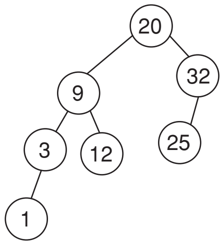


10. Which of the following is the binary tree after deleting 15?

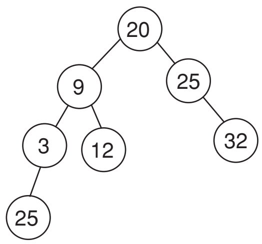
(A)



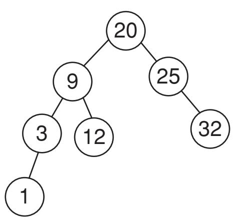
(B)



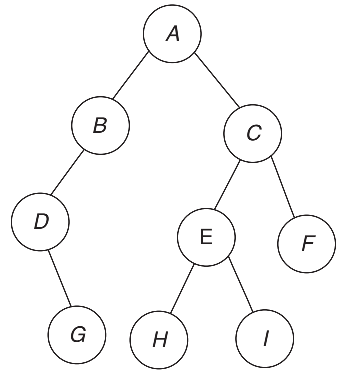
(C)



(D)



For questions 11, 12 and 13 below, use this figure



11. What is the post-order expression?
(A) ABDGCEJHIF (B) GDBHIEFCA
(C) DGBAHEICF (D) ABHIEFCDG

12. What is the pre-order expression?
(A) ABDGCEHIF (B) ABHIEFCDG
(C) DGBAHEIFCF (D) GDBHIEFCA

13. What is the in-order expression?
(A) ABDGCEHIF (B) GDBHIEFCA
(C) DGBAHEICF (D) ABHIEFCDG

14. In a 3-ary tree every internal node has exactly 3 children. The number of leaf nodes in such a tree with 6 internal nodes will be
(A) 13 (B) 12 (C) 11 (D) 10

15. Minimum number of swaps needed to convert the array 89, 19, 14, 40, 17, 12, 10, 2, 5, 7, 11, 6, 9, 70 into a max heap
(A) 2 (B) 3 (C) 1 (D) 0

Previous Years' Questions

1. In a binary tree with n nodes, every node has an odd number of descendants. Every node is considered to be its own descendant. What is the number of nodes in the tree that have exactly one child? **[2010]**
(A) 0 (B) 1
(C) $(n-1)/2$ (D) $n-1$

2. The following C function takes a singly-linked list as input argument. It modifies the list by moving the last element to the front of the list and returns the modified list. Some part of the code is left blank.

```
typedef struct node {
int value;
struct node *next;
}     Node;
Node *move_to_front(Node *head) {
Node *p, *q;
if ((head = = NULL || (head->next = = NULL)) return head;
q = NULL; p = head;
while (p-> next !=NULL) {
            q = p;
            p = p->next;
}

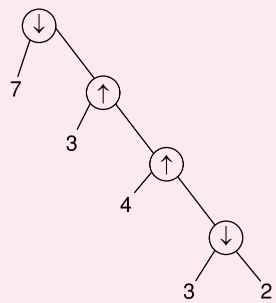
return head;
}
```

Choose the correct alternative to replace the blank line. **[2010]**
(A) `q = NULL; p->next = head; head = p;`
(B) `q->next = NULL; head = p; p->next = head;`
(C) `head = p; p->next = q; q->next = NULL;`
(D) `q->next = NULL; p->next = head; head = p;`

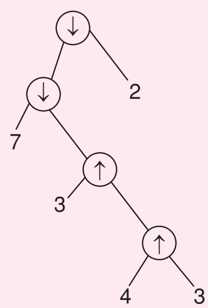
3. Consider two binary operators '↑' and '↓' with the

precedence of operator ↓ being lower than that of the operator ↑. Operator ↑ is right associative while operator ↓ is left associative. Which one of the following represents the parse tree for expression (7 ↓ 3 ↑ 4 ↑ 3 ↓ 2)? **[2011]**

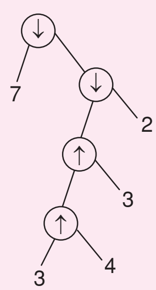
(A)



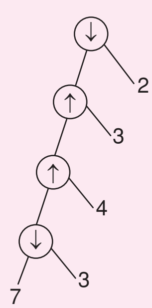
(B)



(C)



(D)



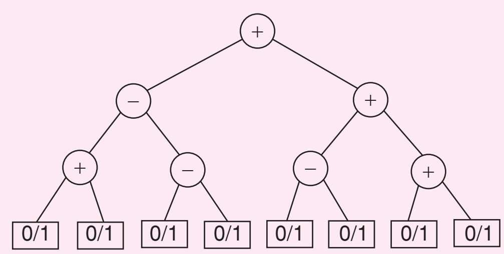
4. The height of a tree is defined as the number of edges on the longest path in the tree. The function shown in the pseudocode below is invoked as "height(root)" to compute the height of a binary tree rooted at the tree pointer "root".

```
int height(treeptr n)
{if (n == NULL) return -1;
if (n → left ==NULL)
if (n → right == NULL) return 0;
else return [B1] ;       //Box 1
else {h1 = height (n → left);
if (n → right== NULL) return (1 + h1);
else {h2 = height (n → right);
return [B2] ;     //Box 2
          }
     }
}
```

The appropriate expressions for the two boxes B_1 and B_2 are **[2012]**

(A) B_1: (1 + height ($n \to$ right))
 B_2: (1 + max (h_1, h_2))
(B) B_1: (height ($n \to$ right))
 B_2: (1+ max(h_1, h_2))
(C) B_1: height ($n \to$ right)
 B_2: max(h_1, h_2)
(D) B_1: (1 + height ($n \to$ right))
 B_2: max(h_1, h_2)

5. Consider the expression tree shown. Each leaf represents a numerical value, which can either be 0 or 1. Over all possible choices of the values at the leaves, the maximum possible value of expression represented by the tree is ______. **[2014]**



6. Consider the pseudocode given below. The function **Dosomething()** takes as argument a pointer to the root of an arbitrary tree represented by the *leftMostChild-rightSibling* representation. Each node of the tree is of type **treenode.** **[2014]**

```
type def struct treeNode* treeptr;
struct treeNode
{
treeptr leftMostChild, rightSibling;
};
int Dosomething (treeptr tree)
```

```
{
int value = 0;
if (tree ! = NULL){
if (tree - > leftMostChild = = NULL)
value = 1;
else
value=Dosomething(tree->leftMostChild);
value = value +Dosomething (tree - > right
Sibling);
}
return (value);
}
```

When the pointer to the root of a tree is passed as the argument to **DoSomething**, the value returned by the function corresponds to the
(A) Number of internal nodes in the tree
(B) Height of the tree
(C) Number of nodes without a right sibling in the tree
(D) Number of leaf nodes in the tree

7. The height of a tree is the length of the longest root-to-leaf path in it. The maximum and minimum number of nodes in a binary tree of height 5 are **[2015]**

(A) 63 and 6, respectively
(B) 64 and 5, respectively
(C) 32 and 6, respectively
(D) 31 and 5, respectively

8. Which of the following is/are correct inorder traversal sequence(s) of binary search tree(s)? **[2015]**
I. 3, 5, 7, 8, 15, 19, 25
II. 5, 8, 9, 12, 10, 15, 25
III. 2, 7, 10, 8, 14, 16, 20
IV. 4, 6, 7, 9, 18, 20, 25
(A) I and IV only (B) II and III only
(C) II and IV only (D) II only

9. Consider a max heap, represented by the array: 40, 30, 20, 10, 15, 16, 17, 8, 4 **[2015]**

Array Index	1	2	3	4	5	6	7	8	9
Value	40	30	20	10	15	16	17	8	4

Now consider that a value 35 is inserted into this heap. After insertion, the new heap is
(A) 40, 30, 20, 10, 15, 16, 17, 8, 4, 35
(B) 40, 35, 20, 10, 30, 16, 17, 8, 4, 15
(C) 40, 30, 20, 10, 35, 16, 17, 8, 4, 15
(D) 40, 35, 20, 10, 15, 16, 17, 8, 4, 30

10. A binary tree *T* has 20 leaves. The number of nodes in *T* having two children is ______ **[2015]**

11. Consider a binary tree *T* that has 200 leaf nodes. Then, the number of nodes in *T* that have exactly two children are ______. **[2015]**

12. While inserting the elements 71, 65, 84, 69, 67, 83 in an empty binary search tree (BST) in the sequence shown, the element in the lowest level is **[2015]**
(A) 65 (B) 67
(C) 69 (D) 83

13. Consider the following New–order strategy for traversing a binary tree: **[2016]**
- Visit the root;
- Visit the right subtree using New – order;
- Visit the left subtree using New – order;

The New – order traversal of the expression tree corresponding to the reverse polish expression
3 4 * 5 – 2 ^ 6 7 * 1 + – is given by:
(A) + – 1 6 7 * 2 ^ 5 – 3 4 *
(B) – + 1 * 6 7 ^ 2 – 5 * 3 4
(C) – + 1 * 7 6 ^ 2 – 5 * 4 3
(D) 1 7 6 * + 2 5 4 3 * – ∧ –

14. Let *T* be a binary search tree with 15 nodes. The minimum and maximum possible heights of *T* are: **[2017]**
Note: The height of a tree with a single node is 0.
(A) 4 and 15 respectively
(B) 3 and 14 respectively
(C) 4 and 14 respectively
(D) 3 and 15 respectively

15. The pre-order traversal of a binary search tree is given by 12,8,6,2,7,9,10,16,15,19,17,20. Then the post-order traversal of this tree is: **[2017]**
(A) 2, 6, 7, 8, 9, 10, 12, 15, 16, 17, 19, 20
(B) 2, 7, 6, 10, 9, 8, 15, 17, 20, 19, 16, 12
(C) 7, 2, 6, 8, 9,10, 20, 17, 19, 15, 16, 12
(D) 7, 6, 2, 10, 9, 8, 15, 16, 17, 20, 19, 12

16. The postorder traversal of a binary tree is 8, 9, 6, 7, 4, 5, 2, 3, 1. The inorder traversal of the same tree is 8, 6, 9, 4, 7, 2, 5, 1, 3. The height of a tree is the length of the longest path from the root to any leaf. The height of the binary tree above is ______. **[2018]**

17. The number of possible min-heaps containing each value from {1, 2, 3, 4, 5, 6, 7} exactly once is ______. **[2018]**

Test

Programming and Data Structure (Part I)

Time: 60 min.

Directions for questions 1 to 30: Select the correct alternative from the given choices.

1. What is the behavior of following code?

auto int *I*;

int main( )

```
{
}
```

(A) Compiler error (B) No error
(C) Linker error (D) Runtime error

2. What is the output of following code:

#define scanf "%S is a string"

int main( )

```
{
printf(scanf, scanf);
}
```

(A) is a string is a string
(B) %S is a string is a string
(C) %S is a string %S is a string
(D) Syntax error

3.
```
void rec_fun (int n, int sum)
{
int k = 0, j = 0;
if(n = = 0) return;
k = n%10; j = n/10;
sum+ = k;
rec _fun(j, sum);
printf("%d\t", k);
}
main ( )
{
int a = 2048; sum = 0;
rec _fun(a, sum);
printf("%d", sum);
}
```

What does the above program print?
(A) 8 4 0 2 14
(B) 8 4 0 2 0
(C) 2 0 4 8 18
(D) 2 0 4 8 0

4.
```
int fun (int * p, int n)
{
if (n < = 0) return 0;
else
if(*P % 2 = = 0)
return *p + fun(p + 1, n - 1);
else
return *p - fun(p + 1, n -1);
}
main( )
{
int arr[ ] = {56, 48, 55, 10, 49, 14};
printf("% d", fun(arr, 6));
}
```

Which of the following is the output of above function?
(A) 110 (B) –122
(C) 114 (D) 108

5. Consider the function:

```
int fun (int n)
{
static int i = 1;
if (n > = 5) return n;
n = n + i;
i ++;
return fun (n);
}
```

The value returned by *f*(3) is
(A) 6 (B) 7
(C) 8 (D) 9

6. Which of the following code will change a lower case letter to an upper case?
(A) char $C_2 = (C_1 > = `A' \& C_1 < `Z')?$ $`a' + `C_1' - `A': C_1);$
(B) char $C_2 = (C_1 > = `a' \& C_1 < = `z')?$ $`A' - `a' + `C_1') : C_1;$
(C) char $C_2 = (C_1 >= `a' \&\& C_1 <= `z')?$ $`A' + `C_1' - `a': C_1;$
(D) char $C_2 = (C_1 > = `A' \& \& C_1 < = `Z')?$ $`A' - `C_1' + `a': C_1;$

7. The following is a program to find the average length of several lines of text. What should be the lines of code corresponding to 'SecA' and 'SecB'.

```
main( )
{int n, count = 0, sum = 0;
float avg;
secA
```

```
{
count++;
sum + = n;
}
avg = (float) sum/count;
}
int linecount (void)
{
char line [80];
int count = 0;
while (secB)
{
count ++;
}
return (count);
}
```

(A) Sec A: while ($n > 0$)
Sec B: line [count]! = 0
(B) Sec A: while (linecount ( ) > 0)
Sec B: (line [count] = getch ( ) ! = '\n')
(C) Sec A: while ((n = linecount( ) > 0)
Sec B: (line [count] = getch ( ) ! = '\n')
(D) None of these

8. What is the meaning of following declaration? int(*f_1) ( );

(A) f_1 is a function which returns a pointer to an integer number.
(B) f_1 is a pointer to a function which returns an integer number.
(C) f_1 is a function which takes an integer pointer.
(D) f_1 is a pointer to an integer number.

9. Which of the following represents the statement: "x is a pointer to a group of one dimensional 20 element arrays".

(A) int *x[20]; (B) int *x[10] [20];
(C) int **x[20]; (D) int (*x) [20];

10. What will be the output of the following code?

```
int number[ ] = {18, 20, 22, 24};
main( )
{
int *q;
q = number;
q + = 4;
printf("%d",*q);
}
```

(A) 24 (B) Compiler error
(C) syntax error (D) –24

11.
```
main( )
{
char fname[ ] = "TIME 4 EDUCATION";
time4(fname);
}
time4(char fname[5])
{
fname + = 7;
printf("%s", fname);
fname = 2;
printf("%s", fname);
}
```

What is the output of above code?

(A) 4 EDUCATION
(B) EDUCATION
(C) TIME 4 EDUCATION
(D) EDUCATION ME 4 EDUCATION

12. What will be output of following code?

```
int main( )
{
extern int x;
x = 13;
printf ("%d", x);
return 0;
}
```

(A) 13
(B) Vary from compiler
(C) Linker error
(D) Undefined symbol

13. What is the output of the following code?

```
main( )
{
int x = y = z = 100;
int i;
i = x > y < z;
printf("% d", i);
}
```

(A) 0 (B) 1
(C) error (D) No output

14. In the following code, how many times 'while' loop will be executed?

```
int count = 0;
while (count < 32767)
count++;
```

(A) 32767
(B) 32766
(C) infinite times
(D) varies from complier to compiler

15. #define SUM(x)$x + x * x$

#define DIF(x)$x * x - x$

```
int main( )
{
float y = SUM(5) /DIF(5);
printf("%f", y);
}
```

(A) 1.5 (B) 0
(C) 2 (D) 1

16. Which of the following is a correct description of void (* ptr[10]) ( ) ;

(A) ptr is an array of 10 pointers to functions returning type void.
(B) ptr is an array of 10 functions returning pointers of type void.
(C) ptr is an array of 10 functions returning void *.
(D) ptr is an array of data elements of type void.

17.

```
int main( )
{
int p = 2, g = 2;
printf(" %d%d", p < < g, p > > g);
}
```

Output of above code is

(A) 1 16 (B) 4 0
(C) 16 4 (D) 8 0

18. Which of the following is equivalent expression for $P = a * 16 + b/8$;

(A) $P = (a << 4) + (b >> 2)$
(B) $P = (a >> 4) - (b << 2)$
(C) $P = (a << 4) + (b >> 3)$
(D) $P = (a << 4) + (b << 3)$

19. What is the output of the below code?

```
main( )
{
int I = 0, *j = &I;
f1(j);
*j = *j + 10;
printf(" %d%d", I, j);
}
f1(int *k)
{
*k+ = 15;
}
```

(A) 20 55 (B) 25 25
(C) 45 55 (D) 35 35

20.

```
int rec_f2(int r)
{
if (r = = 1 || r= = 0)
return 1;
if (r % 2 = = 0)
return(rec_f2 (r/2)+ 2);
else return ((rec_f2(r - 1) + 3);
}
main( )
{
printf ("%d", rec_f2(7));
}
```

Which of the following is the output of above program?

(A) 10 (B) 11
(C) 13 (D) 0

21.

```
int guest(int a);
int host(int b);
main( )
{
int p = 50, q = 100, r ;
for (r = 0; r < 2; r ++)
{
q = guest(p) + host(p);
printf(" %d", q);
}
}
int guest (int a)
{
int y;
y = host(a);
return(y);
}
int host (int a)
{
static int y = 0;
y = y + 1;
return (a + y);
}
```

The output of above code will be

(A) 103 107 (B) 107 103
(C) 110 107 (D) 107 110

22. Choose the best matching between groups A and B:

Group A		Group B	
1	Volatile	P	Queue
2	Function pointer	Q	Auto
3	Default	R	Guest and host
4	FIFO	S	Switch–case

(A) 1 – S, 2 – Q, 3 – R, 4 – P
(B) 1 – Q, 2 – P, 3 – R, 4 – S

(C) 1 – Q, 2 – R, 3 – S, 4 – P
(D) 1 – R, 2 – Q, 3 – P, 4 – S

23. Which of the following expression represents the statement: "*P* is a function that accepts a pointer to a character array".

(A) int *p*(char **a*[ ]); (B) int (**p*) (char (**a*)[ ]);
(C) int **p* (char **a*); (D) int *p*(char (**a*) [ ]);

24.
```
void arr_fun(int [ ] [3]);
main( )
{
int x[3][3] = {{10, 20, 30}, {40, 50, 60},
{70, 80, 90}};
arr_fun(x);
printf("%d", x[2][1]);
}
void arr_fun (int y[ ][3])
{
++y;
y[1][1] = 9;
}
```
What is the output of the above code?

(A) 80 (B) 90
(C) 70 (D) None of these

25.
```
#define F – 1
#define T 1
#define N 0
main( )
{
if(N)
printf(" %s", "GOOD");
else
if(F)
printf(" %s", "MORNING");
else
printf(" %s", "GOOD NIGHT");
}
```
Output of above code will be

(A) GOOD
(B) MORNING
(C) GOOD MORNING
(D) GOOD NIGHT

26. An external variable

(i) is defined once and declared in other functions.
(ii) is globally accessible by all functions.
(iii) cannot be static
(iv) is defined after main( )

(A) (i) and (ii) (B) (i), (ii) and (iii)
(C) (ii), (iii) and (iv) (D) (i), (ii), (iii), (iv)

Common Data for Questions 27 and 28:

Consider the following code:
```
int f(int P)
{
if(P < = 0) return 1;
if(P% 10 = = 0)
return f(P – 2); //X
else
return f(P – 3); //Y
}
main( )
{
printf(" %d", f(30));
}
```

27. What will be the output of above code?

(A) 10 (B) 50
(C) 100 (D) 1

28. What will be the output if the lines labeled *X* and *Y* are changed as follows:

X: return $3 + f(P/2)$;
Y: retrun $2 + f(P/3)$;

(A) 4 (B) 6
(C) 8 (D) 10

Common data for Questions 29 and 30:
```
1. float fn1(float n, int a)
2. {
3. float P, S;
   int I;
4. for(S = x, P = 1, I = 1; P = P * x * x;
5. I < a; I ++)
   S = S + P/(l);
6. return (S);
7. }
8. int f(int x)
9. {
10. int f = 1;
11. for (int i = 1; i < = n; i++)
12. f = f * i;
13. return (f);
14. }
```

29. Output of above code for fn1(2.1, 20) is

(A) $x + \frac{x^2}{2!} + \frac{x^4}{4!} + ...a + 2.1$

(B) $\frac{x - x^3}{3!} + \cdot a + 2.1$

(C) $1+\frac{x}{1!}+\frac{x^2}{2!}+$

(D) $1+\frac{x}{1!}+\frac{x^3}{3!}+\frac{x^5}{5!}+\cdot a+2.1$

30. When the statement numbered 4, 5, 6, 7 are replaced by

```
{for (S = 1, P = -x, I = 1; I < a; i++)
P = P * x * x -1;
S = S + P/f(I);
}
```

What will be the approximation of $f(x)$?

(A) $1+x-x^2+x^3\ldots$

(B) $1-\frac{x}{1!}+\frac{x^3}{3!}-$

(C) $1-\frac{x}{1!}+\frac{x^2}{2!}+\frac{x^3}{3!}+\cdots$

(D) $1-\frac{x}{1!}+\frac{x^2}{2!}-\frac{x^3}{3!}+\cdots$

Programming and Data Structures Test 1

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. Which one of the following is true about a strict binary tree with 16 leaf nodes?
   (A) has exactly 2^5 nodes
   (B) has atmost $2^5 - 1$ nodes
   (C) has atmost 30 nodes
   (D) has exactly 31 nodes

2. Consider 2 sorted lists of size 50 and 60 respectively. Find the number of comparisons needed in the worst case by merge sort algorithm?
   (A) 109 (B) 50
   (C) 60 (D) 3000

3. The print statement printf("%*d*", ++10); prints
   (A) 11 (B) 10
   (C) An error message (D) Garbage value

4. Consider the following C code segment

```
if(ptr!= NULL)
        *ptr = NULL; else  *ptr = NULL;
```

Which of the following has the same effect as the above code?

```
   (I) if(ptr)
        *ptr = NULL; else *ptr = NULL
  (II) *ptr = NULL;
 (III) if(!ptr)
        *ptr = NULL; else *ptr = NULL;
  (IV) if(ptr= NULL)
        *ptr = NULL; else *ptr = NULL;
```

   (A) I and III (B) I and IV
   (C) I, III and IV (D) I, II, III and IV

5. Which of the following statements are true?
   (I) Casting refers to implicit type conversion
   (II) Coercion refers to implicit type conversion
   (III) Casting refers to explicit type conversion
   (IV) Coercion refers to explicit type conversion
   (A) I and II (B) II and III
   (C) I and IV (D) III and IV

6. For implementing queue using linked list, the enqueue and dequeue operations are performed as
   (A) Enqueue after the last element, dequeue the first element
   (B) Enqueue in front of the first element, dequeue the first element
   (C) Enqueue after the last element, dequeue the last element
   (D) Enqueue in front of the first element, dequeue the last element

7. The tree transversal in which the node is processed before the recursive call to the child nodes complete?
   (A) Postorder (B) Preorder
   (C) Inorder (D) Level order

8. What is the number of '*n*' node binary trees with items 1, 2, …, *n* that have identical postorder and inorder transversals?
   (A) $\frac{n+1}{2}$ (B) n
   (C) 1 (D) $n!$

9. Which of following uses the unweighted single source shortest path problem?
   (A) Breadth First Search (B) Dijkstra's algorithm
   (C) Kruskal's algorithm (D) Depth First Search

10. Which one of the following data structure is best suited to check whether an arithmetic expression has balanced parentheses?
    (A) List (B) Queue
    (C) Stack (D) Tree

11. What is the output returned by following code?

```
# include <stdio.h>
int main( )
{
for(;NULL;)
printf ("TIME");
return 0;
}
```

    (A) T (B) TIME
    (C) Infinite loop (D) Compilation Error

12. Which of the following statements are TRUE?
    (I) Recursive programs are efficient
    (II) Binary search using a linear linked list is efficient
    (III) The worst case Time complexity of Quick sort is $O(n^2)$
    (IV) As the number of entries in the hash table increases, the number of collisions also increase.
    (A) II and III (B) I and III
    (C) III and IV (D) II and IV

13. If the processor supports only the immediate and direct addressing modes, then which one of the following programming language feature cannot be implemented on that processor?
    (A) Arrays
    (B) Pointers
    (C) Records
    (D) Recursive procedures with local variables

14. Which one of the following is true about the result returned by function under value-result and reference parameter passing conventions?
    (A) May differ in the presence of exceptions
    (B) Do not differ
    (C) Differ in the presence of loops
    (D) Differ in all cases

15. If L_1 is deterministic context free and L_2 is regular then which of the following is also deterministic context free?

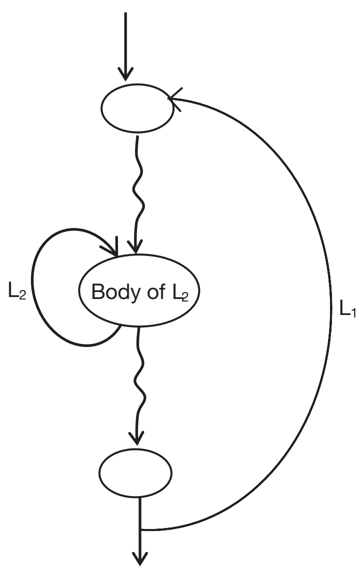
(i) $L_1 \cup L_2$ (ii) $L_1 \cap L_2$
(iii) L_2
(A) (i), (ii) Only (B) (ii), (iii) Only
(C) (ii) Only (D) (i), (ii) and (iii)

16. Consider the following C code segment

```
main ()
{
static int i;
for(putchar('G'); putchar('A');
putchar('E'))
    {
putchar ('T');
if(i == 2)
   break;
else
   i++;
   }
}
```

The output will be
(A) Syntax error (B) GAETETET
(C) GATEATEATE (D) GATEATEAT

17. Consider the below flow graph, which has two loops: L_1 and L_2



Let variables x, y are assigned registers in L_1 but not in L_2, then which of the following actions are TRUE?
(i) Store x, y on entry to L_2
(ii) Load x, y on entry to L_2
(iii) Load x, y on exit from L_2
(iv) Store x, y on exit from L_2
(A) (i), (ii)
(B) (i), (iii)
(C) (ii), (iv)
(D) (iii), (iv)

18. Consider the following recursive function

$$\text{fun}(n) = \begin{cases} 2 & \text{if } n = 0 \\ x & \text{if } n = 1 \\ 2\,\text{fun}\,(n-1) + 4\,\text{fun}\,(n-2) & \text{if } n \geq 2 \end{cases}$$

If the value of fun(4) is 88, then the value of 'x' is
(A) –1 (B) 0
(C) 2 (D) 1

19. What will be the output of following code?

```
# include<stdio.h>
int main ( ) {
int b, a = 6;
b = - a - - ;
printf ("%d %d", b, a);
}
```

(A) 6 5 (B) –5 5
(C) – 6 5 (D) compilation error

20. Which of the following is the prefix expression for the given infix expression?
$A - B * C + (D/E)/F * G$
(A) $+ - A * BC * / DE / FG$
(B) $+ - A * BC / DE / * FG$
(C) $+ - A * BC * || DEFG$
(D) $- A * BC + * || DEFG$

21. The following postfix expression with single digit operands is evaluated using a stack 4 2 2 ∗ / 2 3 ^ + 5 –
The top two elements of the stack after the evaluation of ^ are (^ is the exponentiation operator)
(A) (8, 1) (B) (9, 1)
(C) (5, 9) (D) (5, 1)

22. A circular queue of capacity (m –1) elements is implemented with an array of m elements. Insertion and deletion operation are done at rear and front respectively. Initially rear and front are initialized to zero. The condition to check whether the queue is full and empty are
(A) full :(rear + 1) mod m == front
  empty :(front + 1)mod m == rear
(B) full:(front +1) mod m == rear
  empty: rear == front
(C) full : (rear +1) mod m == front
  empty : rear == front
(D) full : rear == front
  empty : (rear +1) mod m == front

23. The number of comparisons needed to search a single linked list of length 'n' for a given element in worst case scenario is?
(A) $\frac{n}{2}$ (B) $\log_2 n - 1$
(C) $\log_2 n$ (D) n

24. Consider the following C code segment and predict the correct output ?

```
# define cube(x) (x*x*x)
main ()
```

```
{
int i, j = 4;
i = cube (j ++);
printf ("%d %d", i, j);
}
```

(A) 64 7 (B) 64 4
(C) 125 7 (D) 343 7

25. What will be the output of the following C code segment?

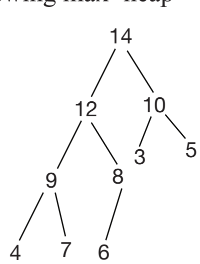
```
# define m(a, b) (((a)>(b))?(a):(b))
main ()
{
int x = 10, y = 5, z = 0;
z = m(++x, y++);
printf("%d %d %d", x, y, z)
}
```

(A) 11 6 11 (B) 12 7 12
(C) 13 6 13 (D) 12 6 12

26. Which of the following sequence of array elements form a valid binary max heap?
(A) 35, 21, 10, 14, 15, 9, 6
(B) 50, 18, 14, 15, 17, 16, 12
(C) 40, 20, 14, 15, 21, 4, 11
(D) 9, 6, 4, 2, 1, 5, 3

27. Construct a binary min-heap with following elements inserted in order 5, 10, 2, 6, 8, 4, 3, 12, 15, 1, 7
What will be the resultant binary min-heap after the above operation?

(A) 
(C) 
(B) 
(D) 
28. Consider the following max–heap



On deleting the element '14' from the max–heap, the resultant heap will be

(A) 
(C) 
(B) 
(D) 
29. Consider a complete binary tree of 15 nodes. How far are the most distant two nodes? (Assume each path count as 1)
(A) about 2 $\log_2 15$ (B) about $\log_2 15$
(C) about 3 $\log_2 15$ (D) about 4 $\log_2 15$

30. Let the last vertex visited of a complete binary tree in preorder, inorder and postorder are denoted by LPRE, LIN, LPOST respectively. Then which of the following is always true?
(A) LPRE = LPOST (B) LIN = LPRE
(C) LIN = LPOST (D) None of the above

31. Consider the following pairs of traversals on a labeled binary tree. Which of these pairs identify a tree uniquely?
(I) Inorder and Postorder
(II) Preorder and Postorder
(III) Preorder and Inorder
(IV) Level order and Postorder
(A) II only (B) I and III
(C) III only (D) IV only

Common Data for Questions 32 and 33:

```
Consider the following C code segment
int x, y, z = 0;
void fun(void);
main()
{
static int x = 4; ---------------S1
fun();
x++;
fun();
printf("\n %d %d" , x, y);
}
void fun(void)
} static int x = 6; ------------S2
int y =2;
x + = ++y;
```

```
printf("\n %d %d", x, y);
}
```

32. What output is generated by the given code segment?

(A) 9 3
9 3
5 0

(B) 9 3
12 3
5 0

(C) 9 3
9 3
9 3

(D) 9 3
12 4
5 garbage value

33. What output is generated by the given code segment if S_1 is replaced by auto int $x = 4$; S_2 is replaced by register int $x = 6$;

(A) 9 3
12 3
5 0

(B) 9 3
12 3
4 0

(C) 9 3
9 3
5 0

(D) 9 3
9 3
5 Garbage value

Linked Data Questions 34 and 35

Construct a binary search tree with elements 55, 40, 65, 60, 35, 20, 25, 70, 50, 10, 15. Inserted in order.

34. What will be the output of post order transversal of the BST?
(A) 15, 10, 25, 20, 35, 40, 50, 60, 70, 65, 55
(B) 15, 10, 25, 20, 35, 50, 40, 60, 70, 65, 55
(C) 15, 10, 25, 20, 35, 40, 60, 50, 70, 65, 55
(D) 15, 10, 25, 20, 35, 40, 70, 65, 60, 50, 55

35. In the above binary search tree, to locate the number 15, which of the following probe sequence is possible?
(A) 55, 40, 35, 25, 10, 15 (B) 55, 40, 50, 20, 10, 15
(C) 55, 40, 35, 20, 10, 15 (D) 55, 60, 35, 25, 10, 15

Answer Keys

1. D	**2.** A	**3.** C	**4.** D	**5.** B	**6.** A	**7.** B	**8.** C	**9.** A	**10.** C
11. B	**12.** C	**13.** B	**14.** A	**15.** D	**16.** D	**17.** B	**18.** D	**19.** C	**20.** C
21. A	**22.** C	**23.** D	**24.** A	**25.** D	**26.** A	**27.** C	**28.** C	**29.** A	**30.** D
31. B	**32.** B	**33.** C	**34.** B	**35.** C					

Hints and Explanations

1. Number of nodes of strict binary tree
$= (2n - 1)$; $n \rightarrow$ number of leaf nodes Choice (D)

2. $m + n - 1$
That is $50 + 60 - 1 = 109$ Choice (A)

8. Unique tree can be created using postorder and inorder transversals
$\therefore$ Only 1 tree is possible with same item that have identical post order and in order Choice (C)

11. Here NULL is micro constant, value of this symbolic constant is '0' as defined in stdio.h.
So for loop should not execute any time because initial condition is false. But it is bug of turbo C compiler. Loop will execute one time and it will print: TIME
Choice (B)

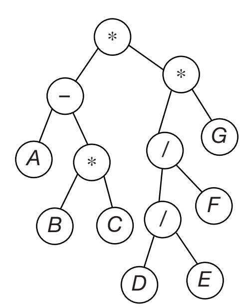
15. L_1 is DCFL
L_2 is regular.
Every regular language is DCFL. $L_1 \cup L_2$ and $L_1 \cap L_2$ are also DCFL's. Choice (D)

17. As the variables belongs to L_1 we need to store x, y on entry to L_2 and load x, y on exit from L_2. Choice (B)

18. $T(4) = 2T(3) + 4T(2)$
$T(3) = 2T(2) + 4T(1)$
$T(2) = 2T(1) + 4T(0) \rightarrow 8 + 2x$
Back substitute the value of $T(2)$
$\therefore \quad x = 1$ Choice (D)

19. $b = -a$ - -
$b = -6$ - -
$b = -6$
Now value of variable 'a' will be 5.
Choice (C)

20.

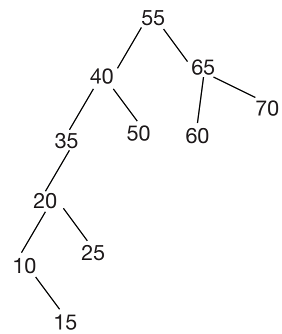


Prefix : $* - A * BC * \| DEFG$ Choice (C)

24. $i = 4 * 4 * 4 = 64$
$j = 4 + 3 = 7$ Choice (A)

25. The line $z = m(++x, y++)$ is replaced by
$z = (++x) > (y++)\ ?\ (++x) : (y++)$ Choice (D)

34.



15, 10, 25, 20, 35, 50, 40, 60, 70, 65, 55 Choice (B)

Programming and Data Structures Test 2

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. Consider the following C program

```
main ()
{
char c = 'i'
while (c++ < = 'p')
putchar (xyz);
}
```

What should replace '*xyz*' such that the output will be: ijklmnop

(A) c (B) c – 1
(C) c++ (D) – c

2. Which of the following is/are true regardless of implementations?

I. sizeof(short) equals sizeof(int)
II. sizeof(int) equals sizeof(unsigned)
III. sizeof(double) is not less than sizeof(float)

(A) I only (B) II and III
(C) I and II (D) I, II and III

3. Consider the following type definition:
typedef char *c*[10];
c Array [6];
What will be the sizeof(Array)?
(Assume one character occupies 1 byte)

(A) 16 bytes (B) 60 bytes
(C) 10 bytes (D) 30 bytes

4. For implementing stack using linked list, the push and pop operations are performed as

(A) Push after the last element, pop the last element
(B) Push in front of the first element, pop the last element
(C) Push in front of the first element, pop the first element
(D) Push after the last element, pop the first element

5. Which of the following tree traversals have worst case complexity more than linear time?

(A) Level order (B) Preorder
(C) Inorder (D) None of the above

6. The stack is not used to implement:

(A) Level order (B) infix
(C) Polish (D) Reverse Polish

7. Which of the following data structures has the least height

(A) B–tree of order 4 (B) B–tree of order 3
(C) B–tree of order 5 (D) B–tree of order 6

8. Which one of the following algorithm solves the positive weighted single source shortest path problem?

(A) Breadth first search (B) Depth first search
(C) Kruskal's algorithm (D) Dijkstra's algorithm

9. The minimum spanning tree problem uses:

(A) Breadth first search (B) Dijkstra's algorithm
(C) Kruskal's algorithm (D) Depth first search

10. Heap allocation is required for languages that:

(A) support dynamic data structures
(B) support recursion
(C) use dynamic scope rules
(D) None of the above

11.

```
# include <stdio.h>
int main ( )
{
extern int X;
x = 40;
printf ("%d", X);
}
```

(A) 0 (B) 40
(C) Error (D) Garbage value

12. Forward declaration is absolutely necessary:

(A) if the function call precedes its definition
(B) if the function call precedes its definition and the function returns a non-integer quantity
(C) if a function returns a non-integer quantity
(D) None of the above

13. Faster access to non-local variable is achieved using an array of pointers to activation records is called a/an:

(A) Queue (B) Stack
(C) Heap (D) Activation tree

14. A binary tree *T* has 64 leaf nodes. The number of nodes of degree 2 in *T* is:

(A) 64 (B) $\log_2 64$
(C) 63 (D) 32

15. The number of leaf nodes in a rooted tree of 10 nodes with each node having 0 or 3 children is:

(A) 4 (B) 5
(C) 6 (D) 7

16. Consider the following C code segment

```
main()
{
static int i;
while(printf("%d",printf("hi")))
{
printf ("by");
if (i == 2)
break;
else
i++;
}
}
```

The output will be:

(A) hi2bybyby (B) hi2byhi2byhi2by
(C) hi2byhi2byhi2byhi2by (D) Syntax error

17. Consider the following for loop
for (putchar('*G*'); putchar (0);putchar ('*E*'))
putchar ('*T*');
The above loop will be executed
(A) Infinite times (B) 2 times
(C) 0 time (D) Syntax error

18. Consider below code fragment:

```
Test (list, n)
Nodeptr *list;
int n;
{
    Nodeptr  p, q;
    int m;
    q = NULL;
    p = *list;
    while (p! = NULL)
      if(p ® info = = n)
      {
        p = p → next;
        if(q = = NULL)
      {
        freenode(*list);
        *list = p;
      }
      else
        deleteafter(q, &m);
      }
      else
      {
        q = p;
        p = p → next;
      }
    }
```

deleteafter (*q*, & *m*) next node after *q* will be deleted and deleted data will be stored in *m*. freenode (*list) frees a node. Then what is the function of Test?
(A) Deletes first and last elements of the list.
(B) Deletes all nodes whose 'info' field contains the value '*n*'.
(C) Deletes all nodes whose next 'info' field contains the value '*n*'.
(D) Delete '*n*' nodes from the list.

19. What is the output of the following?
enum coin {penny, nickel, dime, quarter = 25, half – dollar, dollar}; printf ("%d %d", dime, dollar);
(A) 2,5 (B) 2,27
(C) 3,27 (D) 2,25

20. Convert the given infix expression into post fix $A - B * C + (D / E) * F / G$
(A) $ABC * - DE / F * G / +$
(B) $ABC * - DE / FG * / +$
(C) $ABC * -$ DE $/ + F * G /$
(D) $ABC * - DE / + FG / *$

21. What will be the output of the following C code?

```
# define square(x) (x * x)
int main ( )
{
int i, j = 3
i = square(j+2)
printf("%d", i);
}
```

(A) Error (B) 25
(C) 11 (D) None of the above

22. What will be the output of the following *C* code segment?

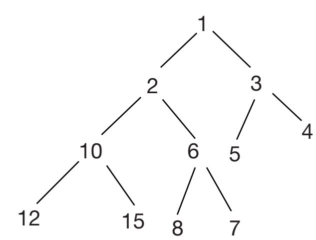
```
# define function(i, j) i##j
main ( )
{
int var1 = 10, var12 = 30;
printf("%d",function(var1, 2));
}
```

(A) Error (B) 30
(C) 0 (D) 12

23. Which of the following sequence of array elements form a valid binary min-heap?
(A) 4, 7, 10, 8, 9, 12, 13
(B) 23, 25, 28, 24, 32, 30
(C) 14, 17, 25, 30, 15, 24, 33
(D) 60, 80, 70, 65, 85, 90, 95

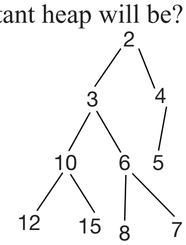
24. Construct a binary max heap with elements 4, 14, 3, 6, 9, 5, 10, 12, 7, 8 inserted inorder
Which of the following is the correct sequence of element of binary max-heap in the array, representation
(A) 14, 12, 10, 9, 8, 3, 5, 7, 4, 6
(B) 14, 12, 10, 9, 8, 3, 5, 4, 7, 6
(C) 14, 12, 10, 8, 9, 5, 3, 4, 7, 6
(D) 14, 12, 10, 8, 9, 4, 3, 5, 7, 6

25. Consider the following min-heap

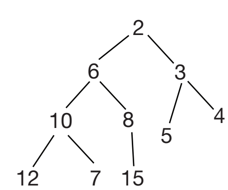


On deleting the element '1' from the min-heap, the resultant heap will be?

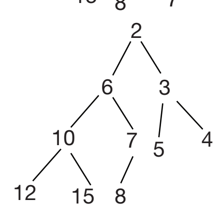
(A)



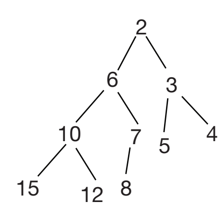
(B)



(C)



(D)



26. The inorder and preorder transversal of binary tree are *l j m i n k o* and *i j l m k n o* respectively. Then the post-order traversal of the binary tree is:
(A) *m l j o n k i* (B) *m l j n o k i*
(C) *l m n o j k i* (D) *l m j n o k i*

27. How many distinct binary search trees can be created out '*n*' distinct keys?
(A) $n!$ (B) n^2
(C) $\frac{2nC_n}{n+1}$ (D) $2n + 1$

28. Find the maximum number of nodes in a binary tree of height 13? (height of a binary tree is the maximum number of edges in any root to leaf path)
(A) $2^{12} - 1$ (B) $2^{14} - 1$
(C) 2^{13} (D) 2^{14}

29. The following sequence of operations is performed on a stack push(30), push(40), pop, push(30), push(40), pop, pop, pop, push(40), push(30), pop, pop
What is the sequence of popped out values?
(A) 40, 40, 30, 40, 30, 30
(B) 30, 40, 40, 30, 40, 30
(C) 40, 40, 30, 30, 30, 40
(D) 40, 30, 40, 30, 30, 40

Common Data Questions 30 and 31:

```
Consider the function
find(int i, int j)
{
return ((i <j) ? 0 : (i - j));
}
```

30. Let *a*, *b* be two non-negative integers. The call find (*a*, find(*a*, *b*)) can be used to find the:
(A) Positive difference of *a*, *b*
(B) Maximum of *a*, *b*
(C) Minimum of *a*, *b*
(D) Sum of *a*, *b*

31. Let *a*, *b* be two non-negative integers, then which of the following calls, finds the positive difference of *a* and *b*?
(A) find(*a*, *b*) + find(*b*, *a*) (B) *a* + find(*a*, *b*)
(C) *b* + find(*a*, *b*) (D) find(*a*, find(*a*, *b*))

Linked Data Questions 32 and 33:
Consider the following C code fragment

```
static char array [4][4] =
{"bat", "tub", "hot", "pig"};
char (*p) [4] = array;
```

32. What will be the output of (∗ (array [2] + 1))
(A) Prints address of '*o*' (B) Prints '*u*'
(C) Prints '*h*' (D) Prints *o*

33. Which of the following prints the character '*g*'?
(A) putchar (∗(ptr + 3)+2)
(B) putchar (∗(∗(ptr + 3)+2))
(C) putchar (∗((array +3) + 2))
(D) Both (B) and (C)

Linked Data Questions 34 and 35:
A binary search tree is generated by inserting the elements in the following order:
20, 25, 30, 15, 18, 12, 35, 8, 23, 5, 13

34. Which one of the following is the valid preorder transversal on the above binary search tree?
(A) 20, 15, 12, 8, 5, 13, 18, 23, 25, 30, 35
(B) 20, 15, 12, 8, 5, 13, 18, 35, 25, 23, 30
(C) 20, 15, 12, 8, 5, 13, 18, 25, 23, 30, 35
(D) 20, 15, 12, 8, 5, 13, 18, 25, 30, 23, 35

35. Which one of the following is the valid post order transversal on the binary search tree?
(A) 5, 8, 13, 12, 18, 15, 23, 35, 25, 30, 20
(B) 5, 8, 13, 12, 18, 15, 23, 25, 30, 20, 35,
(C) 5, 8, 13, 12, 18, 23, 15, 25, 30, 35, 20
(D) 5, 8, 13, 12, 18, 15, 23, 35, 30, 25, 20

Answer Keys

1. B	**2.** B	**3.** B	**4.** C	**5.** D	**6.** A	**7.** D	**8.** D	**9.** C	**10.** A
11. C	**12.** B	**13.** D	**14.** C	**15.** D	**16.** B	**17.** C	**18.** B	**19.** B	**20.** A
21. C	**22.** B	**23.** A	**24.** B	**25.** C	**26.** D	**27.** C	**28.** B	**29.** C	**30.** C
31. A	**32.** D	**33.** D	**34.** C	**35.** D					

Hints and Explanations

3. 10 × 6 = 60 bytes Choice (B)

5. All the other options requires linear time only
Choice (D)

6. Polish → preorder
Reverse polish → post order
Level order → BFS Choice (A)

11. Output of the given program will be "Linker error – undefined symbol *X*"
External variables are declared outside a function.
Choice (C)

12. By default the return type is int.
Choice (B)

14. No. of nodes of degree 2 = $n - 1$
where n – no. of leaf nodes Choice (C)

15. $\lceil 2n + 1)/3 \rceil$

$$\left\lceil \frac{2 \times 10 + 1}{3} \right\rceil = \left\lceil \frac{21}{3} \right\rceil = 7$$ Choice (D)

18. Given code deletes all nodes whose 'info' field contains 'n'. If the 'info' field equal to n delete that node and repeat this for the remaining list. Choice (B)

19.

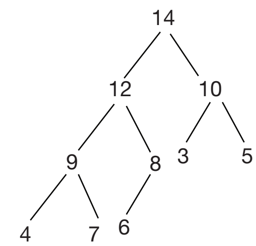
Penny	0
nickel	1
dime	2
quarter	25
half-dollar	26
dollar	27

Choice (B)

21. $(j + \underbrace{2 * j}_{\text{Higher precedence}} + 2)$ Choice (C)

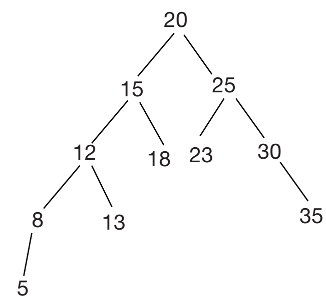
22. $i\#\#j$ performs macro concatenation
$\therefore$ var1, 2 becomes 'var12', the value of var12 is 30
Choice (B)

24.



Choice (B)

34.



Choice (C)

Programming and Data Structures Test 3

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Dynamic checking is performed (at the time of)
   (A) translation (B) execution
   (C) before the execution (D) semantic analysis
2. Which variables are preferable for smaller and faster programs?
   (A) auto variables (B) static variables
   (C) global variables (D) register variables
3. C language implements
   (A)Static scoping (B) dynamic scoping
   (C) both (A) and (B) (D) None of the above
4. Which of the following language doesnot support recursion
   (A) C (B) PROLOG
   (C) PASCAL (D) FORTRAN
5. Consider the following program segment:

```
A (int x)
{
if (x = = 0)
return;
else
{
A(x/10);
printf("%d /t", x);
}
}
```

   What is the output when A (1 2 3 4) is called
   (A) 1 2 3 4 1 2 3 1 1 2 (B) 1 1 2 1 2 3 1 2 3 4
   (C) 1 1 2 3 1 2 1 2 3 4 (D) 1 2 3 4 1 2 3 1 2 1
6. What is the return value when *A* ("TIME") is called from given program segment?

```
int A(char * S)
{
char * P = S;
while (*P! = '/0')
P++;
return P – S; }
```

   (A) 1 (B) 2
   (C) 3 (D) 4
7. The following statement $x + y = z$ in 'C' language is:
   (A) correct (B) invalid
   (C) impossible (D) None of the above
8. The order in which actual arguments are evaluated in a function call is:
   (A) from left to right (B) from right to left
   (C) unpredictable (D) None of the above
9. Which of the following is true for the getche ( ) library function?
   (A) It returns a character when a key is pressed.
   (B) It returns a character when the enter key is pressed.
   (C) It doesn't display a character on the screen.
   (D) It displays a character on the screen.
10. The following declaration float (**A*) (void *,void *) means:
    (A) *A* is function returning a pointer to a float that has two void * arguments.
    (B) *A* is a pointer to a function with float as the arguments.
    (C) *A* is a function with void * as arguments and returns float pointer.
    (D) *A* is a function that has two void * arguments and returns float.

Linked Answer Questions 11 and 12:

Consider the following recursive function:

```
A(m, n)
{
if (m = = 0)
return n + 1;
else if (n = = 0)
A (m – 1, 1);
else
A(m – 1, A(m, n – 1));
}
```

11. What is the value returned when *A* (1, 1) is called:
    (A) 2 (B) 3
    (C) 4 (D) 5
12. The number of function calls when *A* (1, 1) is called:
    (A) 2 (B) 3
    (C) 4 (D) 5
13. Pointers are of unsigned:
    (A) integer data type (B) character data type
    (C) float data type (D) None of the above

Common Data Questions 14 and 15:

Consider the following program segment:

```
int x[3] [5] = {
{1, 2, 3, 4, 5}
{6, 7, 8, 9, 10},
{11, 12, 13, 14, 15}}
int *n = &x;
```

14. The value of $*(*(x + 1) + 3)$ is:
    (A) 7 (B) 8
    (C) 9 (D) None of the above
15. The value of $*(n + 5) + 1$ is:
    (A) 7 (B) 5
    (C) 3 (D) None of the above
16. Consider the declaration char *A* (int (*) (char, float)) int *B*(char, float)

Which of the following function invocation is valid?

(A) A (*B) (B) A (&B)

(C) A (B) (D) None of the above

17. The expression

6 – 2 + 3 – 4 * 2 will evaluate to –1 if

(A) – is left associative and – has precedence over *

(B) – is right associative and – has precedence over *

(C) – is right associative and * has precedence over –

(D) None of the above

18. Which of the following is not the functionality of pre processing?

(A) Macro substitution

(B) Conditional compilation

(C) Inclusion of named files

(D) None of the above

19. Consider the program segment:

```
int x = 10;
A( )
{
int x = 20;
B ( );
}
B( )
{
printf ("%d", x);
}
main ( )
{
A ( )
}
```

What is the out put of above program

(A) 10

(B) 20

(C) prints 10 or 20 (depends on compiler)

(D) compilation error

20. Consider the program segment:

```
int x = 40;
A ( )
{
int y = 60;
B ( );
}
B ( )
{
printf('%d", x);
}
main ( )
{
int x = 50;
A( ) ;
}
```

The output of the above program is:

(A) 40 (B) 50

(C) 60 (D) Compilation error

21. In the above code given in Q. 20, if the above language implements Dynamic scoping then output of the above code is:

(A) 40

(B) 50

(C) 60

(D) None of these

22. Consider the following program:

```
int k;
k = n; // 'n' is some integer
while (k > 0)
k = k/2;
```

The number of comparisons made in the execution of the loop is:

(A) $[\log_2 n]$ (B) $1 + [\log_2 n]$

(C) n (D) $\left[\log\left(\frac{n}{2}\right)\right]+1+1$

23. Consider the following program:

```
A (int x, int y)
{
if (x > = y)
return [1 + A(x - y, y)];
else
return 0;
}
```

What is the functionality of above routine A( )?

(A) It returns the number of function calls

(B) It performs the subtraction between two numbers (x and y).

(C) It performs division of the two given numbers (x and y).

(D) It returns the greater value among the two numbers (x and y).

24. What does the following fragment of C-program print;

char* s = "TIME = HYD";

char* $p = s;$

printf ("%u %u", p, s);

(A) 2000 2006

(B) 2006 2008

(C) 2010 TIME HYD

(D) 2000 2000

25. Consider the following program segment:

```
main ( )
{
static char a[3] [4] = {"time",
   "gate", "2015"}
putchar (**a);
}
```

What will be the output of above program?

(A) prints time

(B) prints gate

(C) prints 2015

(D) None of the above

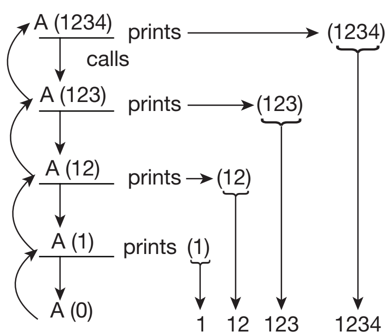
Answer Keys

1. C	**2.** D	**3.** A	**4.** D	**5.** B	**6.** D	**7.** B	**8.** C	**9.** A	**10.** D
11. B	**12.** C	**13.** A	**14.** C	**15.** A	**16.** C	**17.** C	**18.** D	**19.** A	**20.** A
21. B	**22.** B	**23.** C	**24.** D	**25.** D					

Hints and Explanations

1. 'Dynamic checking is performed before the execution. Choice (C)

5.

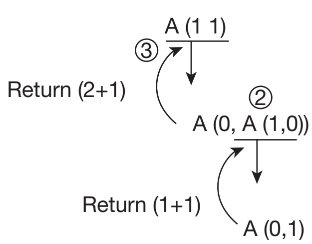


Choice (B)

6. It returns the string length i.e., 4. Choice (D)

7. Left side of assignment operator (=) could not be an expression. Choice (B)

11.



Choice (B)

12. From the above, the function calls are 4. Choice (C)

14. $*(*(x + 1) + 3)$

This is equivalent to $x[1]$ $[3]$, which is 9. Choice (C)

15. $*(n + 5) + 1$

1	2	3	4	5	6	7	8	....
0	1	2	3	4	5	6	7	

The above pointer expression maps to $n[6]$ in memory location which is 7. Choice (A)

16. The function '*A*' means *A* is a function (returning character) whose only argument is a pointer to a function that takes a character and float as arguments and returns as integer. The name of a function can be used as the starting address of the function (i.e., pointer to it). Choice (C)

17. $6 - 2 + 3 - 4 * 2$

$\downarrow$

$= 6 - 2 + 3 - 8$

$\downarrow$

$= 6 - 2 + (-5)$

$= 6 - 2 - 5$

$= 6 - 7 = -1.$ Choice (C)

19. The given program is in 'C' language, it implements static scoping.

When $A(\ )$ is called which calls $B(\ )$ it will check the 'x', values in $B(\ )$. As it is not present, it checks for the 'x' values out of the $B(\ )$ and it will print x as '10'. Choice (A)

20. As 'C' language implements static scoping, when $A(\ )$ is called, which will call $B(\ )$ which has to print 'x', first it will check in $B(\ )$ for the 'x' value then it goes out of the $B(\ )$ (global section) and prints 40. Choice (A)

21. If dynamic scoping is implemented, when $B(\ )$ wants to print 'x' it, first checks for 'x' in $B(\ )$ as it is not present, it checks in the function from where it is called (i.e., in $A(\ )$)

$\therefore$ It prints 50. Choice (B)

22. Here 'k' value is n from the loop, 'k' values will be:

$$n, \frac{n}{2}, \frac{n}{4}, \frac{n}{8}, \ldots, 1$$

let the loop is iterated for 't' times as the sequence is in G.P. then t^{th} term will be 1.

$$\therefore \quad n\left(\frac{1}{2}\right)^{t-1} = 1 = \frac{1}{n}$$

$2^{t-1} = n$

$(t - 1) \log_2 2 = \log_2 n$

$t - 1 = \log_2 n$

$t = 1 + \log_2 n$ Choice (B)

23. The function A( ) returns Quotient.

i.e., it performs division among the two given numbers. Choice (C)

24. Both p and s points to same address, prints same values. Choice (D)

25. **a will map to 1^{st} character in the array it prints't'. Choice (D)

Programming and Data Structures Test 4

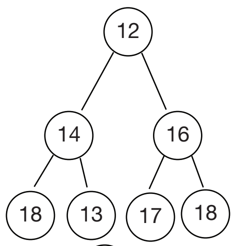
Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

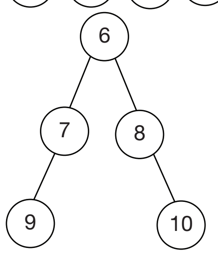
1. Which of the following data structure(s) can be used to represent Stack, Queue, Binary Tree, Hash Table, Heap and Graph?
   (A) Array (B) Singly linked list
   (C) Doubly linked list (D) Both (A) and (C)

2. Which of the following is a min heap?

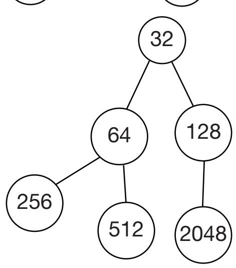
(A)



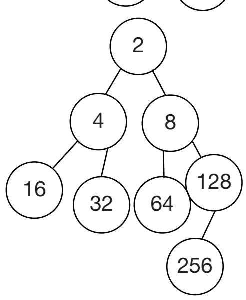
(B)



(C)



(D)



3. Which traversal of a binary search tree will give the result in an ascending order of elements?
   (A) Preorder
   (B) In-order
   (C) Post-order
   (D) None of the above (a special code is required to print elements in ascending order)

4. Which of the following cannot be implemented using self-referential structure?
   (A) Graphs (B) AVL trees
   (C) Splay trees (D) B-Trees

5. Which of the following is TRUE about the AVL tree?
   (1) AVL tree is a binary tree.
   (2) The search time of AVL tree will be always less than (or) equal to the search time of binary search tree.
   (3) AVL tree is binary search tree with maximum balancing factor of 2.
   (A) Only (1) (B) Only (1) and (2)
   (C) Only (1) and (3) (D) All the above

6. Which of the following is suitable for the data that contains a relationship between pairs of elements, which is not necessarily hierarchical in nature?
   (A) Heaps (B) AVL Trees
   (C) Graphs (D) B-Trees

7. What is the Number of Null links in a Binary Tree of 'n' nodes?
   (A) n (B) $n + 1$
   (C) $n - 1$ (D) $n/2$

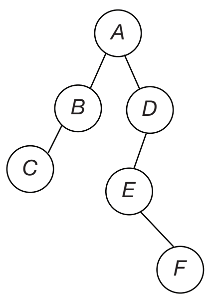
8. What is the number of stacks that should be used to implement a queue?
   (A) 1 (B) 2
   (C) 3 (D) 4

9. Consider the recursive function for fibonacci sequence:
```
fib (n)
{
if (n ==0)
return 0;
else if (n==1)
return 1;
else
return fib (n - 1) + fib (n - 2);
}
```
   What is the Number of additions required, when $fib(n)$ is invoked ?
   (A) $fib(n + 1) - 1$ (B) $fib\ (n + 1) + 1$
   (C) $fib\ (n + 1) - \text{n}$ (D) $fib\ (n + 1) + n$

10. Which of the following tree traversals are necessary to get the unique pattern of a tree structure?
   (A) Only In-order
   (B) In-order and pre-order
   (C) Post-order and pre-order
   (D) All the above

Common data for questions 11 and 12:
```
Consider the following routines:
struct Binary
{
struct Binary * Left ;
int data;
struct Binary * Right;
}
```

```
void F1 (struct Binary *t)
{
if (t)
{
printf("%d", t → data);
F2(t → Left);
F2(t → Right);
}
}
void F2(struct binary * t)
{
if (t)
{
F1(t → Left);
printf("%d", t → data);
F1 (t → Right);
}
}
Let us consider a tree
```



11. If $F1(t)$ is called on the above tree with t as root node (A), what is its output?
(A) *ABCDEF* (B) *ACBFED*
(C) *ABDCFE* (D) *ACBEFD*

12. When $F2(t)$ is called on this tree, with root as the parameter that is ($F2$(root)), what is its output?
(A) *BCADEF* (B) *BCDEFA*
(C) *DEFBCA* (D) *DEFABC*

13. What is the prefix expression of the expression $a + b * c/d \wedge e \wedge f - g$
(A) $-/ * + a\, b\, c$ d $\wedge \wedge e\, f\, g$
(B) $- +$ a/$* b\, c \wedge d \wedge e\, f\, g$
(C) $- + a \wedge \wedge / * b\, c\, d\, e\, f\, g$
(D) $\wedge \wedge + a / * b\, c\, d\, e - f\, g$

14. What does the function DO( ) does on a queue?

```
void DO( )
{
if (!Q is empty)
{
int temp = dequeue ( );
DO ( );
enqueue (temp);
}
}
```

(A) queue remains same
(B) elements will get reversed in a queue
(C) elements are removed and reinserted in the same queue
(D) queue remains empty

15. Fill in the blanks for the routine A( ).

```
A( ) will delete the elements in circular queue.
Initially Front = Rear = -1
A(Q, N, Front, Rear, Y) // N is size of a queue, Q is an array to store circular Queue.
{
if (Front == -1)
{
printf("Queue is underflow");
exit (1);
}
Y = Q(Front);
if(I)
Front = Rear = -1;
else
{
if (Front == N)
(II);
else
Front = Front + 1;
}
```

return *Y;*

(A) I. Front == Rear +1 II. Front = –1
(B) I. Front == Rear II. Front = –1
(C) I. Front == (Rear +1) II. Front = 0
(D) I. Front == Rear II. Front = 0

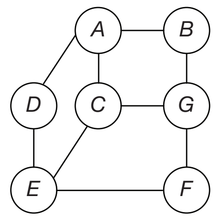
16. Consider the following routine:
struct node

```
{
int data;
struct node → link;
};
void DO (struct node → p, struct node → q)
{
if (q)
{
DO (q, q → link);
q → link = p;
}
else
head = p;
}
```

When DO(head, head → link) is implemented on singly linked list, the resultant list,
(A) is a reversal of given list
(B) remains the same

(C) is a circular linked list
(D) None of these

17. Consider the graph below;



Which of the following orderings are not possible using depth first search graph traversal:
(A) *A C G F E D B* (B) *A D E F C G B*
(C) *A C G B F E D* (D) *C G B A D E F*

18. What is the time complexity for attaining maximum element from Max heap?
(A) $O(n \log n)$ (B) $O(n)$
(C) $O(\log n)$ (D) $O(1)$

19. Minimum number of nodes in AVL tree of height 5 is (with root at height = 1)
(A) 11 (B) 12
(C) 13 (D) 14

20. Consider a Binary search Tree '*T*' in which every node will be having only right child, there are '*n*' nodes \in tree '*T*'. Time complexity for searching an element will be:
(A) $O(\log n)$ (B) $\left(\log\left(\frac{n}{2}\right)\right)$
(C) $O(n)$ (D) $O\left(\frac{n}{2}\right)$

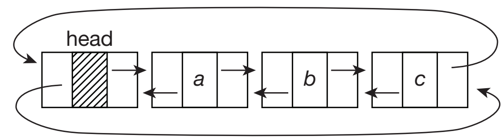
21. Consider post-order and in-order traversal of a tree:
POSTORDER :- DCBGFEA
INORDER :- BDCAFGE
When tree is constructed from above tree traversals then what are the leaf nodes?
(A) *D*, *G* (B) *C*, *F*
(C) *D*, *E* (D) *C*, *G*

Linked Answer for Questions 22 and 23:
Construct an AVL tree with the elements
21, 26, 30, 9, 4, 14, 28, 18

22. What will be the root node for the AVL tree?
(A) 26 (B) 21
(C) 28 (D) 18

23. What will be the post order predecessor of the root node, in the above resultant tree?
(A) 26 (B) 21
(C) 28 (D) 9

Linked Answer for Questions 24 and 25:
Consider the circular doubly linked list given below.



Consider the routine below:

```
struct node
{
sturct node *Lptr ;
int data;
struct node * Rptr;
};
void A ( )
{
struct node → t = head → Rptr;
while (t! = head)
{
swap (t → Lptr, t → Rptr)
t = t → Lptr;
}
swap (head → Lptr, head → Rptr);
}.
```

24. When *A*( ) routine is applied on the given list, the head Right pointer maps to:
(A) Node containing data field as '*a*'
(B) Node containing data field as '*b*'
(C) Node containing data field as '*c*'
(D) The head pointer points to itself

25. To which node *N* (pointer) points when the following operation is performed on the new list formed in the previous question.
(struct node $*$ *N*)
N = Head → Rptr → Rptr → Lptr → Lptr → Rptr;
(A) Head node
(B) Node containing data field as '*a*'
(C) Node containing data field as '*b*'
(D) Node containing data field as '*c*'

Answer Keys

1. A	**2.** C	**3.** B	**4.** A	**5.** B	**6.** C	**7.** B	**8.** B	**9.** A	**10.** B
11. D	**12.** A	**13.** B	**14.** B	**15.** D	**16.** A	**17.** B	**18.** D	**19.** B	**20.** C

HINTS AND EXPLANATIONS

1. Array can be used to represent all the above data structures. Choice (A)

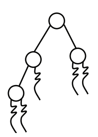
2. Min Heap is a complete Binary tree, with parent node value less than both the child nodes if they exist. Choice (C)

3. Inorder is the traversal of tree which prints data elements in an ascending order. Choice (B)

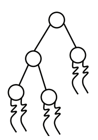
4. Graphs uses adjacency matrix (or) linked representation. Choice (A)

5. AVL tree is binary search tree with balancing factor as 0, +1, –1 and search time as O (log n). Choice (B)

7.



= 5 (for 4 nodes)



= 6 (for 5 nodes)

$\therefore$ For n nodes it will be $(n + 1)$ Null links. Choice (B)

8. 2 stacks required; use one for the Enqueue and the other for Dequeue. Choice (B)

9. Number of additions in a fibonacci sequence will be fib $(n + 1) - 1$. Choice (A)

10. For unique pattern of tree either (pre order + in order) or (post order + in order) are } necessary. Choice (B)

11. Traverse the routines on the tree. Choice (D)

12. Traverse the routines on the tree. Choice (A)

13. $a + b * c / d \wedge e \wedge f - g$

$a + b * c / d \wedge \wedge e f - g$

$a + b * c / \wedge d \wedge e f - g$

$a + * b c / \wedge d \wedge e f - g$

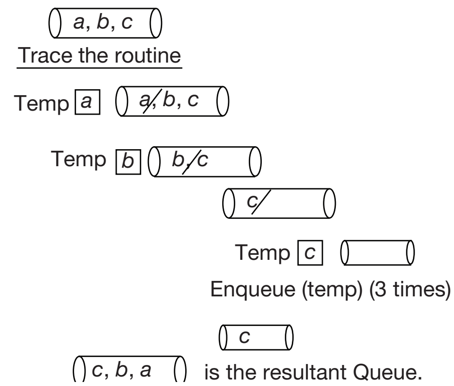
$a + / * b c \wedge d \wedge e f - g$

$+ a / * b c \wedge d \wedge e f - g$

$- + a / * b c \wedge d \wedge e f g.$

Choice (B)

14. Let us consider a queue with 3 elements a, b, c.

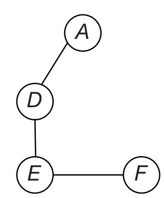


Choice (B)

15. Circular queue deletion routine. Choice (D)

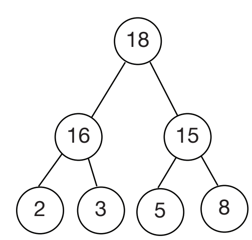
16. It reverses the list. Choice (A)

17. Let us consider option (B)



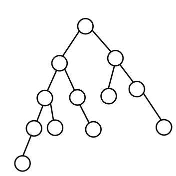
At (F) it can't reach to vertex (C) as it is not adjacent to (F). Choice (B)

18. Let us consider a max heap



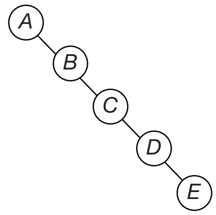
As the maximum element is at the root. To attain root element it takes $O(1)$ time. Choice (D)

19.



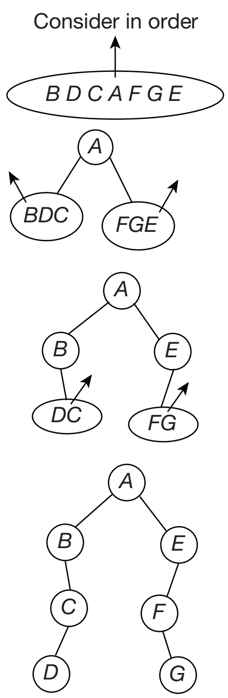
Choice (B)

20. Let us consider 5 nodes



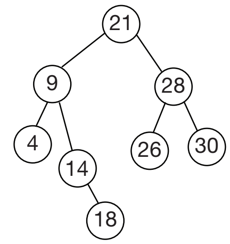
To search an element (E) it has to compare 5 elements
∴ it is $O(n)$. Choice (C)

21. POST: *DCBGFEA*
IN: *BDCAFGE*



Consider in order Choice (A)

22. From the above elements AVL tree will be:



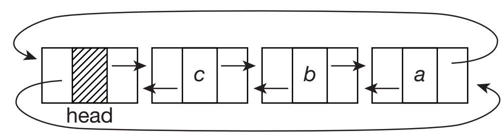
Choice (B)

23. Post order for the above tree is 4 18 14 9 26 30 28 21.
Choice (C)

24. The $A(\ )$ routine will reverse the given list
∴ Head pointer maps to node containing data field as 'c'.

Choice (C)

25.



Traversing the above list with given operation make to point to node containing c. Choice (D)

Algorithm

An algorithm is a finite set of instructions that, if followed, accomplishes a particular task.

All algorithms must satisfy the following.

- Input: Zero or more quantities are externally supplied.
- Output: Atleast one quantity is produced.
- Definiteness: Each instruction should be clear and unambiguous.
- Finiteness: The algorithm should terminate after finite number of steps.
- Effectiveness: Every instruction must be very basic.

Once an algorithm is devised, it is necessary to show that it computes the correct answer for all possible inputs. This process is called algorithm validation. Analysis of algorithms refers to the task of determining how much computing time and storage an algorithm requires.

Analyzing Algorithms

The process of comparing 2 algorithms rate of growth with respect to time, space, number of registers, network, bandwidth etc is called analysis of algorithms.

This can be done in two ways

1. **Priori Analysis:** This analysis is done before the execution; the main principle behind this is frequency count of fundamental instruction.

   This analysis is independent of CPU, OS and system architecture and it provides uniform estimated values.
2. **Posterior analysis:** This analysis is done after the execution. It is dependent on system architecture, CPU, OS etc. it provides non-uniform exact values.

Recursive Algorithms

A recursive function is a function that is defined in terms of itself. An algorithm is said to be recursive if the same algorithm is invoked in the body.

Towers of Hanoi

There was a diamond tower (labeled *A*) with 64-golden disks. The disks were of decreasing size and were stacked on the tower in decreasing order of size bottom to top. Besides this tower there were 2 other diamond towers (labeled *B* and *C*) we have to move the disks from tower A to tower *B* using tower *C* for intermediate storage. As the disks are very heavy, they can be moved only one at a time. No disk can be on top of a smaller disk .

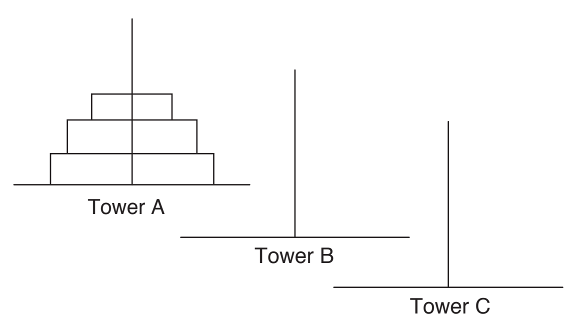

Figure 1 Towers of Hanoi

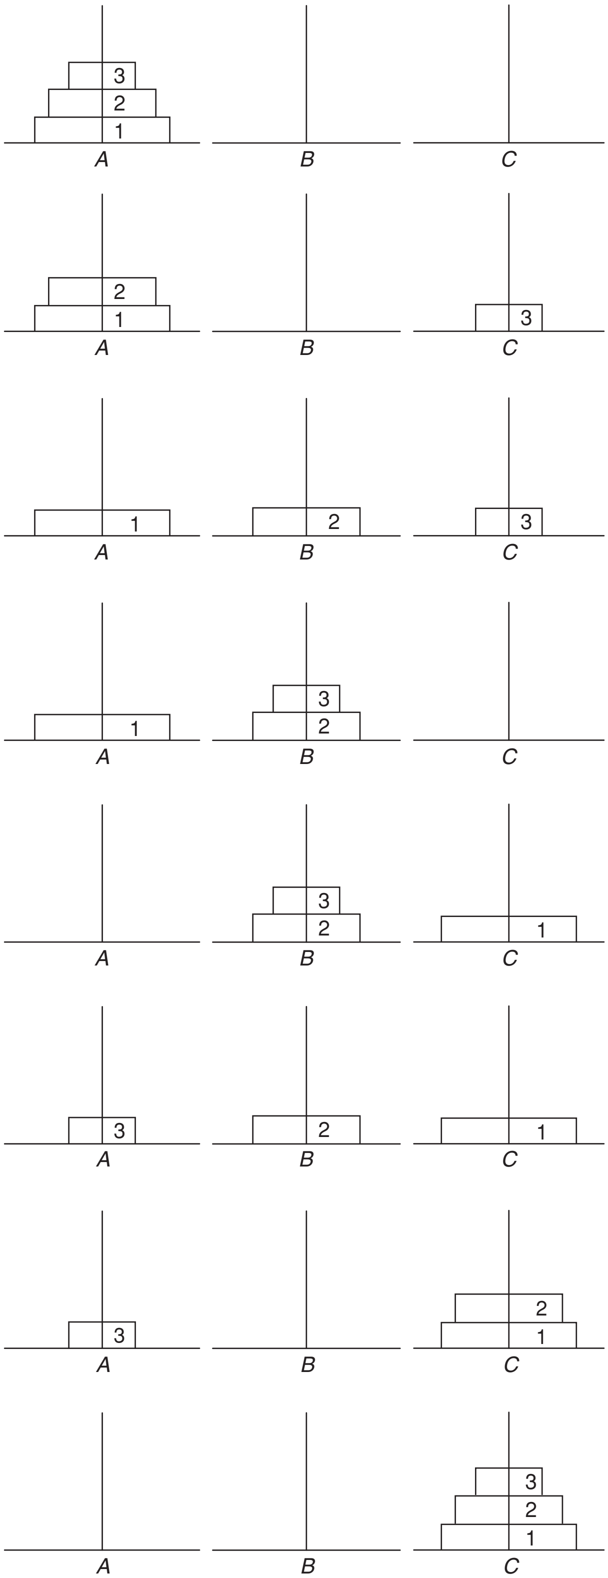
Assume that the number of disks is '*n*'. To get the largest disk to the bottom of tower *B*, we move the remaining (*n* – 1) disks to tower *C* and then move the largest to tower *B*. Now move the disks from tower *C* to tower *B*.

Example:



To move '3' disks from tower A to tower '*C*' requires 7 disk movements

∴ For '*n*' disks, the number of disk movements required is $2^n - 1 = 2^3 - 1 = 7$

Time complexity

$$T(n) = 1 + 2T(n-1)$$
$$T(n) = 1 + 2(1 + 2\,(T(n-2)))$$
$$T(n) = 1 + 2 + 2^2\,T(n-2)$$
$$T(n) = 1 + 2 + 2^2\,(1 + 2T(n-3))$$
$$T(n) = 1 + 2 + 2^2 + 2^3 + T(n-3)$$
$$T(n) = 1 + 2 + 2^2 + \cdots + 2^{i-1} + 2^i\,\mathrm{T}(n-i)$$

$$T(n) = \sum_{i=0}^{n-1} 2^i$$

The time complexity is exponential, it grows as power of 2.

$$\therefore \quad T(n) \cong O(2^n)$$

Space complexity

The space complexity of an algorithm is the amount of memory it needs to run to completion. The measure of the quantity of input data is called the size of the problem. For example, the size of a matrix multiplication problem might be the largest dimension of the matrices to be multiplied. The size of a graph problem might be the number of edges. The limiting behavior of the complexity as size increases is called the asymptotic time complexity.

- It is the asymptotic complexity of an algorithm which ultimately determines the size of problems that can be solved by the algorithm.
- If an algorithm processes inputs of size '*n*' in time cn^2 for some constant *c*, then we say that the time complexity of that algorithm is $O(n^2)$, more precisely a function $g(n)$ is said to be $O(f(n))$ if there exists a constant *c* such that $g(n) \le c(f(n))$ for all but some finite set of non-negative values for *n*.
- As computers become faster and we can handle larger problems, it is the complexity of an algorithm that determines the increase in problem size that can be achieved with an increase in computer speed.
- Suppose we have 5 algorithms Algorithm 1 – Algorithm 5 with the following time complexities.

Algorithm	Time Complexity
Algorithm – 1	n
Algorithm – 2	$n \log n$
Algorithm – 3	n^2
Algorithm – 4	n^3
Algorithm – 5	$2n$

The time complexity is, the number of time units required to process an input of size '*n*'. Assume that input size '*n*' is 1000 and one unit of time equals to 1 millisecond.

The following figure gives the sizes of problems that can be solved in one second, one minute, and one hour by each of these five algorithms.

Algorithm	Time Complexity	Maximum Problem Size 1 sec	1 min	1 hour
Algorithm – 1	n	1000	6×10^4	3.6×10^6
Algorithm – 2	$n \log n$	140	4893	2.0×10^5
Algorithm – 3	n^2	31	244	1897
Algorithm – 4	n^3	10	39	153
Algorithm – 5	$2n$	9	15	21

From the above table, we can say that different algorithms will give different results depending on the input size. Algorithm – 5 would be best for problems of size $2 \le n \le 9$, Algorithm – 3 would be best for $10 \le n \le 58$, Algorithm – 2 would be best for $59 \le n \le 1025$, and Algorithm – 1 is best for problems of size greater than 1024.

Set Representation

A common use of a list is to represent a set, with this representation the amount of memory required to represent a set is proportional to the number of elements in the set. The amount of time required to perform a set operation depends on the nature of the operation.

- Suppose A and B are 2 sets. An operation such as $A \cap B$ requires time atleast proportional to the sum of the sizes of the 2 sets, since the list representing A and the list representing B must be scanned atleast once.
- The operation $A \cup B$ requires time atleast proportional to the sum of the set sizes, we need to check for the same element appearing in both sets and delete one instance of each such element.
- If A and B are disjoint, we can find $A \cup B$ in time independent of the size of A and B by simply concatenating the two lists representing A and B.

Graph Representation

A graph $G = (V, E)$ consists of a finite, non-empty set of vertices V and a set of edges E. If the edges are ordered pairs (V, W) of vertices, then the graph is said to be directed; V is called the tail and W the head of the edge (V, W). There are several common representations for a graph $G = (V, E)$. One such representation is adjacency matrix, $a|V|X|V|$ matrix M of 0's and 1's, where the ij_{th} element, $m[i, j] = 1$, if and only if there is an edge from vertex i to vertex j.

- The adjacency matrix representation is convenient for graph algorithms which frequently require knowledge of whether certain edges are present.
- The time needed to determine whether an edge is present is fixed and independent of $|V|$ and $|E|$.
- Main drawback of using adjacency matrix is that it requires $|V|^2$ storage even if the graph has only $O(|V|)$ edges.
- Another representation for a graph is by means of lists. The adjacency list for a vertex v is a list of all vertices W adjacent to V. A graph can be represented by $|V|$ adjacency lists, one for each vertex.

Example:

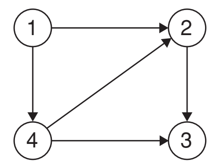


Figure 2 Directed graph

$$\begin{array}{c} \\ 1 \\ 2 \\ 3 \\ 4 \end{array}\begin{array}{c} \begin{array}{cccc} 1 & 2 & 3 & 4 \end{array} \\ \begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \end{bmatrix} \end{array}$$

Figure 3 Adjacency matrix

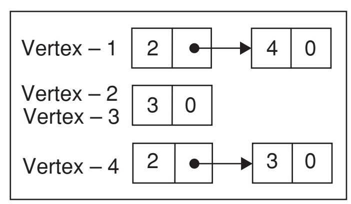

Figure 4 Adjacency lists

There are edges from vertex – 1 to vertex – 2 and 4, so the adjacency list for 1 has items 2 and 4 linked together in the format given above.

- The adjacency list representation of a graph requires storage proportional to $|V| + |E|$, this representation is used when $|E| << |V|^2$.

Tree Representation

A directed graph with no cycles is called a directed acyclic graph. A directed graph consisting of a collection of trees is called a forest. Suppose the vertex 'v' is root of a sub tree, then the depth of a vertex 'v' in a tree is the length of the path from the root to 'v'.

- The height of a vertex 'v' in a tree is the length of a longest path from 'v' to a leaf.
- The height of a tree is the height of the root
- The level of a vertex 'v' in a tree is the height of the tree minus the depth of 'v'.

	Left child	Right child
1	2	6
2	3	4
3	0	0
4	0	5
5	0	0
6	7	8
7	0	0
8	0	9
9	0	10
10	0	0

Figure 5 A binary tree and its representation

- Vertex 3 is of depth '2', height '0' and the level is 2 (Height of tree – depth of '3' = 4 – 2 = 2).
- A binary tree is represented by 2 arrays: left child and right child.
- A binary tree is said to be complete if for some integer k, every vertex of depth less than k has both a left child and a right child and every vertex of depth k is a leaf. A complete binary tree of height k has exactly $(2^{k+1} - 1)$ vertices.
- A complete binary tree of height k is often represented by a single array. Position 1 in the array contains the root. The left child of the vertex in position 'i' is located at position '$2i$' and the right child at position '$2i + 1$'.

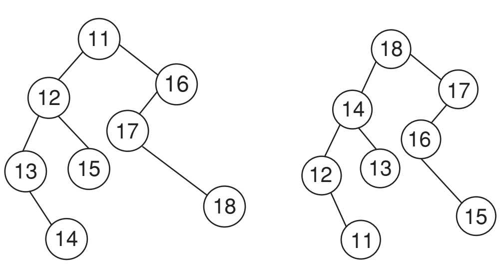
Tree Traversals

Many algorithms which make use of trees often traverse the tree in some order. Three commonly used traversals are pre-order, postorder and inorder.

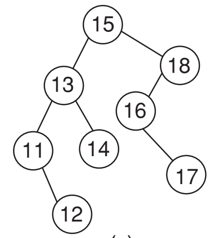
Pre-order Traversal

A pre-order traversal of T is defined recursively as follows:

1. Visit the root.
2. Visit in pre-order the sub trees with roots $v_{1,}\ v_2 \ldots v_k$ in that order.



(a) (b)



(c)

Figure 6 (a) Pre-order, (b) Post-order **(c)** In-order

Post-order traversal

A post-order traversal of T is defined recursively as follows:

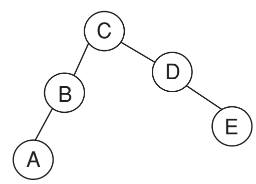
1. Visit in post-order the sub trees with roots v_1, v_2, v_3, … v_k in that order.
2. Visit the root r.

In-order Traversal

An in-order traversal is defined recursively as follows:

1. Visit in in-order the left sub tree of the root 'r'.
2. Visit 'r'.
3. Visit in inorder the right sub tree of r.

Example: Consider the given tree



What are the pre-order, post-order and in-order traversals of the above tree?

Solution: Pre-order – CBADE
Post-order – ABEDC
In-order – ABCDE

Data Structure

A data structure is a way to store and organize data in-order to facilitate access and modifications. No single data structure works well for all purposes, it is important to know the strengths and limitations of several data structures.

Efficiency

Algorithms devised to solve the same problem often differ dramatically in their efficiency. Let us compare efficiencies of Insertion sort and merge sort; insertion sort, takes time equal to C_1n^2 to sort 'n' elements, where C_1 is a constant that does not depend on 'n'. It takes time proportional to n^2, merge sort takes time equal to $C_2n\log n$, C_2 is another constant that also does not depend on 'n'. Insertion sort has a smaller constant factor than merge sort $(C_1 < C_2)$ constant factors are far less significant in the running time.

Merge sort has a factor of 'log n' in its running time, insertion sort has a factor of 'n', which is much larger. Insertion sort is faster than merge sort for small input sizes, once the input size 'n' becomes large enough, merge sort will perform better. No matter how much smaller C_1 is than C_2. There will always be a crossover point beyond which merge sort is faster.

Example: Consider 2 computers, computer A (faster computer), B (slower computer). Computer A runs insertion sort and computer B runs merge sort. Each computer is given 2 million numbers to sort. Suppose that computer A executes one billion instruction per second and computer B executes only 10 million instructions per second, computer A is 100 times faster than computer B ($C_1 = 4$, $C_2 = 50$). How much time is taken by both the computers?

Solution: Insertion sort takes $C_1 * n^2$ time
Merge sort takes $C_2 * n * \log n$ time
$C_1 = 4, C_2 = 50$
Computer A takes

$$\frac{4\times(2\times10^6)^2 \text{ instructions}}{10^9 \text{ instructions/second}} \cong 4000 \text{ seconds}$$

Computer B takes

$$= \frac{50\times2\times10^6\times\log(2\times10^6)\text{ insturctions}}{10^7\text{ instructions/second}}$$
$$= 209 \text{ seconds}$$

By using an algorithm whose running time grows more slowly, even with an average compiler, computer B runs <u>20</u> times faster than computer A. The advantage of merge sort is even more pronounced when we sort ten million numbers. As the problem size increases, so does the relative advantage of merge sort.

Worst-case and average-case analysis

In the analysis of insertion sort, the best case occurs when the array is already sorted and the worst case, in which the input array is reversely sorted. We concentrate on finding the worst-case running time, that is the longest running time for any input of size 'n'.

- The worst-case running time of an algorithm is an upper bound on the running time for any input. It gives us a guarantee that the algorithm will never take any longer.
- The 'average-case' is as bad as the worst-case. Suppose that we randomly choose 'n' numbers and apply insertion sort. To insert an element $A[j]$, we need to determine where to insert in sub-array $A\ [1 \cdots J-1]$. On average half the elements in $A[1 \cdots J-1]$ are less than $A[j]$ and half the elements are greater. So $t_j = j/2$. The average-case running time turns out to be a quadratic function of the input size.

Asymptotic Notations

Asymptotic notations are mostly used in computer science to describe the asymptotic running time of an algorithm. As an example, an algorithm that takes an array of size n as input and runs for time proportional to n^2 is said to take $O(n^2)$ time.

5 Asymptotic Notations:

- O (Big-oh)
- θ (Theta)
- Ω (Omega)
- o (Small-oh)
- ω

How to Use Asymptotic Notation for Algorithm Analysis?

Asymptotic notation is used to determine rough estimates of relative running time of algorithms. A worst-case analysis of any algorithm will always yeild such an estimate, because it gives an upper bound on the running time $T(n)$ of the algorithm, that is $T(n)\ \ g(n)$.

Example:

$a \leftarrow 0$	1 unit	1 time
for $i \leftarrow 1$ to n do{	1 unit	n times
for $j \leftarrow 1$ to i do{	1 unit	$n(n+1)/2$ times
$a \leftarrow a+1$	1 unit	$n(n+1)/2$ times

Where the times for the inner loop have been computed as follows: For each i from 1 to n, the loop is executed i times, so the total number of times is $1+2+3+\cdots+n = \sum_{i=1}^{n} i = n(n+1)/2$

Hence in this case
$T(n) = 1 + n + 2n\ (n+1)/2 = n^2 + 2n + 1$
If we write $g(n) = n^2 + 2n + 1$, then $T(n) \in \theta(g(n))$,
That is $T(n) \in \theta(n^2 + 2n + 1)$, we actually write $T(n) \in \theta(n^2)$, as recommended by the following rule:

- Although the definitions of asymptotic notation allow one to write, for example, $T(n) \in O(3n^2 + 2)$.

We simplify the function in between the parentheses as much as possible (in terms of rate of growth), and write instead $T(n) \in O(n^2)$
For example: $T(n) \in \theta(4n^3 - n^2 + 3)$
$T(n) \in \theta(n^3)$

For instance $O\left(\sum_{i=1}^{n} i\right)$, write $O(n^2)$ after computing the sum.

- In the spirit of the simplicity rule above, when we are to compare, for instance two candidate algorithms A and B having running times ($T_A(n) = n^2 - 3n + 4$ and $T_B(n) = 5n^3 + 3$, rather than writing $T_A(n) \in O(T_B(n))$, we write $T_A(n) \in \theta(n^2)$, and $T_B(n) \in \theta(n^3)$, and then we conclude that A

is better than B, using the fact that n^2(quadratic) is better than n^3(cubic) time, since $n^2 \in O(n^3)$.

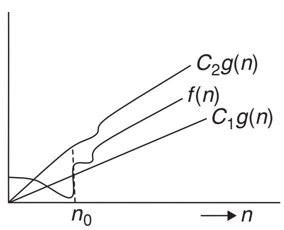
Order of Growth

In the rate of growth or order of growth, we consider only the leading term of a formula. Suppose the worst case running time of an algorithm is $an^2 + bn + c$ for some constants a, b and c. The leading term is an^2. We ignore the leading term's constant coefficient, since constant factors are less significant than the rate of growth in determining computational efficiency for large inputs. Thus we can write, the worst-case running time is $\theta(n^2)$.

We usually consider one algorithm to be more efficient than another if its worst-case running time has a lower order of growth. Due to constant factors and lower order terms, this evaluation may be in error for small inputs. But for large inputs, $\theta(n^2)$ algorithm will run more quickly in the worst-case than $\theta(n^3)$ algorithm.

θ-Notation

A function $f(n)$ belongs to the set $\theta(g(n))$ if there exists a positive constant C_1 and C_2 such that it can be "sand witched" between $C_1g(n)$ and $C_2g(n)$ for sufficiently large n. We write $f(n) \in \theta(g(n))$ to indicate that $f(n)$ is a member of $\theta(g(n))$ or we can write $f(n) = \theta(g(n))$ to express the same notation.



The above figure gives an intuitive picture of functions $f(n)$ and $g(n)$, where we have that $f(n) = \theta(g(n))$, for all the values of 'n' to the right of n_o, the value of $f(n)$ lies at or above $C_1g(n)$ and at or below $C_2g(n)$. $g(n)$ is asymptotically tight bound for $f(n)$. The definition of $\theta(g(n))$ requires that every member $f(n) \in \theta(g(n))$ be asymptotically non-negative, that is $f(n)$ must be non-negative whenever 'n' is sufficiently large.

The θ-notation is used for asymptotically bounding a function from both above and below. We would use θ(theta) notation to represent a set of functions that bounds a particular function from above and below.

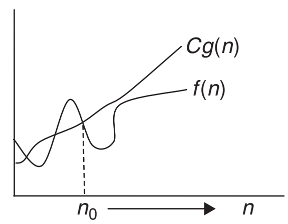
Definition: We say that a function $f(n)$ is theta of $g(n)$ written as $f(n) = \theta(g(n))$ if such exists positive constants C_1, C_2 and n_0 such that $0 \le C_1g(n) \le f(n) \le C_2\, g(n)$, $\forall\, n \ge n_0$.

Example: Let $f(n) = 5.5n^2 - 7n$, verify whether $f(n)$ is $\theta(n^2)$. Lets have constants $c_1 = 9$ and $n_0 = 2$, such that $0 \le f(n) \le C_1\, n^2$, $\forall n \ge n_0$. From example, 4 we have constants $C_2 = 3$, and $n_0 = 2.8$, such that $0 \le C_2\, n^2 \le f(n)$, $\forall n \ge n_0$. To show $f(n)$ is $\theta(n^2)$, we have got hold of two constants C_1 and C_2. We fix the n_0 for θ as maximum $\{2, 2.8\} = 2.8$.

- The lower order terms of an asymptotically positive function can be ignored in determining asymptotically tight bounds because they are insignificant for large n.
- A small fraction of the highest order term is enough to dominate the lower order term. Thus setting C_1 to a value that is slightly smaller than the coefficient of the highest order term and setting C_2 to a value that is slightly larger permits the inequalities in the definition of θ-notation to be satisfied. If we take a quadratic function $f(n) = an^2 + bn + c$, where a, b and c are constants and $a > 0$. Throwing away the lower order terms and ignoring the constant yields $f(n) = \theta(n^2)$.
- We can express any constant function as $\theta(n^0)$, or $\theta(1)$ we shall often use the notation $\theta(1)$ to mean either a constant or a constant function with respect to some variable.

O-Notation

We use O-notation to give an upper bound on a function, within a constant factor.



The above figure shows the intuition behind O-notation. For all values 'n' to the right of n_0, the value of the function $f(n)$ is on or below $g(n)$. We write $f(n) = O(g(n))$ to indicate that a function $f(n)$ is a member of the set $O(g(n))$.

$f(n) = \theta(g(n))$ implies $f(n) = O(g(n))$. Since θ notation is stronger notation than O-notation set theoretically, we have $\theta(g(n)) \subseteq O(g(n))$. Thus any quadratic function $an^2 + bn + c$, where $a > 0$, is in $\theta(n^2)$ also shows that any quadratic function is in $O(n^2)$ when we write $f(n) = O(g(n))$, we are claiming that some constant multiple of $g(n)$ is an asymptotic upper bound on $f(n)$, with no claim about how tight an upper bound it is.

The O-notation is used for asymptotically upper bounding a function. We would use O (big-oh) notation to represent a set of functions that upper bounds a particular function.

Definition We say that a function $f(n)$ is big oh of $g(n)$ written as $f(n) = O(g(n))$ if there exists positive constants C and n_0 such that

$$0 \le f(n) \le Cg(n),\ \forall\ n \ge n_o$$

Solved Examples

Example 1: let $f(n) = n^2$

Then $f(n) = O(n^2)$

$f(n) = O(n^2 \log n)$

$f(n) = O(n^{2.5})$

$f(n) = O(n^3)$

$f(n) = O(n^4) \cdots$ so on.

Example 2: Let $f(n) = 5.5n^2 - 7n$, verity whether $f(n)$ is $O(n^2)$

Solution: Let C be a constant such that

$$5.5n^2 - 7n \leq Cn^2, \text{or } n \geq \frac{7}{c - 5.5}$$

Fix $C = 9$, to get $n \geq 2$
So our $n_0 = 2$ and $C = 9$
This shows that there exists, positive constants $C = 9$ and $n_0 = 2$ such that
$0 \leq f(n) \leq Cn^2$, $\forall\ n \geq n_0$

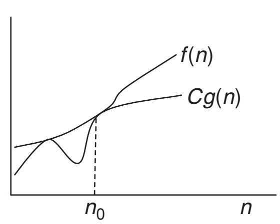
Example 3:

$$h(n) = 3n^3 + 10n + 1000 \log n \in O(n^3)$$

$$h(n) = 3n^3 + 10n + 1000 \log n \in O(n^4)$$

- Using O-notation, we can describe the running time of an algorithm by inspecting the algorithm's overall structure. For example, the doubly nested loop structure of the insertion sort algorithm yields an $O(n^2)$ upper bound on the worst-case running time. The cost of each iteration of the inner loop is bounded from above by $O(1)$ (constant), the inner loop is executed almost once for each of the n^2 pairs.
- $O(n^2)$ bound on worst-case running time of insertion sort also applies to its running time on every input.
- The $\theta(n^2)$ bound on the worst-case running time of insertion sort, however, does not imply a $\theta(n^2)$ bound on the running time of insertion sort on every input, when the input is already sorted, insertion sort runs in $\theta(n)$ time.

Ω *(omega)-notation*



The Ω-notation is used for asymptotically lower bounding a function. We would use Ω(big-omega) notation to represent a set of functions that lower bounds a particular function.

Definition We say that a function $f(n)$ is big-omega of $g(n)$ written as $f(n) = \Omega(g(n))$ if there exists positive constants C and n_0 such that

$$0 \leq Cg(n) \leq f(n)\ ,\ \forall\ n \geq n_0$$

The intuition behind Ω-notation is shown in the above figure. For all values 'n' to the right of n_0, the value of $f(n)$ is on or above $Cg(n)$. For any 2 functions $f(n)$ and $g(n)$ we have $f(n) = \theta(g(n))$ if $f(n) = O(g(n))$ and $f(n) = \Omega(g(n))$. From the above statement we can say that, $an^2 + bn + c = \theta(n^2)$ for any constants a, b and c, where $a > 0$, immediately implies that

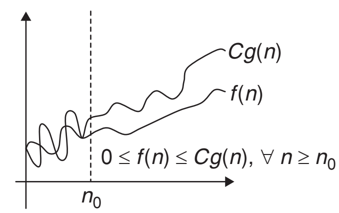
$$\therefore\ an^2 + bn + c = \Omega(n^2)$$

$$\therefore\ an^2 + bn + c = O(n^2)$$

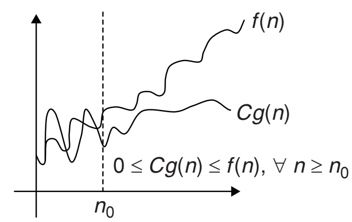
Example 4: Let $f(n) = 5.5n^2 - 7n$.
Verity whether $f(n)$ is $\Omega(n^2)$

Solution: Let C be a constant such that $5.5n^2 - 7n \geq Cn^2$ or $n \geq \frac{7}{5.5 - C}$. Fix $C = 3$, to get $n \geq 2.8$. So, our $n_0 = 2.8$ and $C = 3$

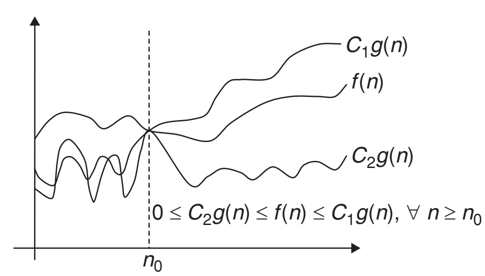
This shows that there exists positive constants $C = 3$ and $n_0 = 2.8$, such that $0 \leq Cn^2 \leq f(n)$, $\forall n \geq n_0$.



(a) $f(n) = O(g(n))$



(b) $f(n) = \Omega(g(n))$



(c) $f(n) = \theta(g(n))$

Figure 7 A diagrammatic representation of the asymptotic notations O, W and q

- Ω-notation describes a lower bound; it is used to bound the best-case running time of an algorithm. The best-case running time of insertion sort is $\Omega(n)$. The running time of insertion sort falls between $\Omega(n)$ and $O(n^2)$, since it falls anywhere between a linear function of 'n' and a quadratic function of 'n'.

- When we say that the running time of an algorithm is $\Omega(g(n))$, we mean that no matter what particular input of size 'n' is chosen for each value of n, the running time on that input is at least a constant times $g(n)$, for sufficiently large 'n'.

O-notation

The asymptotic upper bound provided by O-notation may or may not be asymptotically tight. The bound $2n^3 = O(n^3)$ is asymptotically tight, but the bound $2n = O(n^2)$ is not. We use O-notation to denote an upper bound that is not asymptotically tight.

ω-notation

By analogy, ω-notation is to Ω-notation as o-notation is to O-notation. We use ω-notation to denote a lower bound that is not asymptotically tight.

It is defined as

$f(n) \in \omega(g(n))$ if and only if $g(n) \in o(f(n))$

Comparison of functions

Transitivity

1. $f(n) = \theta(g(n))$ and $g(n) = \theta(h(n))$
$\Rightarrow f(n) = \theta(h(n))$
2. $f(n) = O(g(n))$ and $g(n) = O(h(n))$
$\Rightarrow f(n) = O(h(n))$
3. $f(n) = \Omega(g(n))$ and $g(n) = \Omega(h(n))$
$\Rightarrow f(n) = \Omega(h(n))$
4. $f(n) = o(g(n))$ and $g(n) = o(h(n))$
$\Rightarrow f(n) = o(h(n))$
5. $f(n) = \omega(g(n))$ and $g(n) = \omega(h(n))$
$\Rightarrow f(n) = \omega(h(n))$

Reflexivity

1. $f(n) = \theta(f(n))$
2. $f(n) = O(f(n))$
3. $f(n) = \Omega(f(n))$

Symmetry

$f(n) = \theta(g(n))$ if and only if $g(n) = \theta(f(n))$

Transpose symmetry

1. $f(n) = O(g(n))$ if and only if $g(n) = \Omega(f(n))$
2. $f(n) = o(g(n))$ if and only if $g(n) = \omega(f(n))$

Notations and Functions

Floor and Ceil

For any real number 'x', we denote the greatest integer less than or equal to x by $\lfloor x \rfloor$ called as floor of x and the least integer greater than or equal to x by $\lceil x \rceil$ called as ceiling of x.

$x-1 < \lfloor x \rfloor \le x \le \lceil x \rceil < x+1$ for any integer n,

$$\left\lceil \frac{n}{2} \right\rceil + \left\lceil \frac{n}{2} \right\rceil = n,$$

For any real number $n \ge 0$ and integer $a, b > 0$

$$\left\lceil \frac{\left\lceil \frac{n}{a} \right\rceil}{b} \right\rceil = \left\lceil \frac{n}{ab} \right\rceil$$

$$\left\lfloor \frac{\left\lfloor \frac{n}{a} \right\rfloor}{b} \right\rfloor = \left\lfloor \frac{n}{ab} \right\rfloor$$

Polynomials

Given a non-negative integer k, a polynomial in n of degree 'k' is a function $p(n)$ of the form $p(n) = \sum_{i=0}^{k} a_i n^i$

Where the constants $a_0, a_1, \ldots a_k$ are the coefficients of the polynomial and $a_k \ne 0$.

For an asymptotically positive polynomial $p(n)$ of degree k, we have $p(n) = \theta(n^k)$

Exponentials

For all real $a > 0$, m and n, we have the following identities:

$$a^0 = 1$$
$$a^1 = a$$
$$a^{-1} = \frac{1}{a}$$
$$(a^m)^n = a^{mn}$$
$$(a^m)^n = (a^n)^m$$
$$a^m a^n = a^{m+n}$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots = \sum_{i=0}^{\infty} \frac{x^i}{i!}$$

- For all real x, we have inequality $e^x \ge 1 + x$
- If $x = 0$, we have $1 + x \le e^x \le 1 + x + x^2$

Logarithms

$\lg n = \log_2 n$ (binary logarithm)
$\ln n = \log_e n$ (natural logarithm)
$\lg^k n = (\log n)^k$ (exponentiation)
$\lg \lg n = \lg (\lg n)$ (composition)
For all real $a > 0$, $b > 0$, $c > 0$ and n,
$\log_c (ab) = \log_c a + \log_c b$

$$\log_b a^n = n \log_b a$$

$$\log_b a = \frac{\log_c a}{\log_c b}$$

$$\log_b (1/a) = -\log_b a$$

$$\log_b a = \frac{1}{\log_a b}$$

$$a^{\log_b^c} = c^{\log_b^a}$$

Factorials

$n!$ is defined for integers $n \geq 0$ as

$$n! = \begin{cases} 1 & \text{if } n = 0 \\ (n-1)! * n & n > 0 \end{cases}$$

A weak upper bound on the factorial function is $n! \leq n^n$ since each of the n terms in the factorial product is almost n.

$$n! = o(n^n)$$
$$n! = \omega(2^n)$$
$$\lg(n!) = \theta(n \log n)$$

Iterated Logarithm

The notation $\lg^* n$ is used to denote the iterated logarithm. Let '$\lg^{(i)} n$' be as defined above, with $f(n) = \lg n$. The logarithm of a non-positive number is undefined, '$\lg^{(i)} n$' is defined only if $\lg^{(i-1)} n > 0$;

The iterated logarithm function is defined as $\lg^* n = \min \{i \geq 0 : \lg^{(i)} n \leq 1\}$. This function is a very slowly growing function.

$$\lg^* 2 = 1$$
$$\lg^* 4 = 2$$
$$\lg^* 16 = 3$$
$$\lg^* 65536 = 4$$
$$\lg^*(2^{65536}) = 5$$

Recurrences

When an algorithm contains a recursive call to itself, its running time can often be described by a recurrence. A recurrence is an equation that describes a function in terms of its value on smaller inputs. For example, the worst-case running time $T(n)$ of the merge-sort can be described as

$$T(n) = \begin{cases} \theta(1) & \text{if } n = 1 \\ 2T(n/2) + \theta(n) & \text{if } n > 1 \end{cases}$$

The time complexity of merge-sort algorithm in the worst-case is $T(n) = \theta(n \log n)$

There are 3 methods to solve recurrence relations:

1. Substitution method
2. Recursion-tree method
3. Master method

Substitution Method

In this method one has to guess the form of the solution. It can be applied only in cases when it is easy to guess the form of the answer. Consider the recurrence relation

$$T(n) = 2T(n/2) + n$$

We guess that the solution is $T(n) = O(n \log n)$ we have to prove that

$$T(n) \leq c\, n \log n \quad (\therefore c > 0)$$

Assume that this bound holds for $\lfloor n/2 \rfloor$

$$T(n/2) \leq c(n/2).\log(n/2) + n$$
$$T(n) \leq 2(c(n/2 \log(n/2)) + n$$
$$\leq cn \log n - cn \log 2 + n$$
$$\leq cn \log n - cn + n$$
$$\leq cn \log \qquad (\therefore c \geq 1)$$

Recursion-tree Method

In a recursion-tree, each node represents the cost of single sub problem somewhere in the set of recursive function invocations. We sum the costs within each level of the tree to obtain a set of per-level costs, and then we sum all the per-level costs to determine the total cost of all levels of the recursion. Recursion trees are useful when the recurrence describes the running time of a divide-and-conquer algorithm.

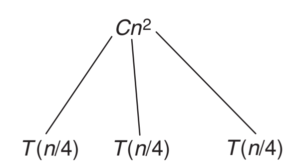
Example:

Consider the given recurrence relation

$$T(n) = 3T(n/4) + \theta(n^2)$$

We create a recursion tree for the recurrence

$$T(n) = 3T(n/4) + Cn^2$$



The Cn^2 term at the root represents the cost at the top level of recursion, and the three sub trees of the root represent the costs incurred by the sub problems of size $n/4$.

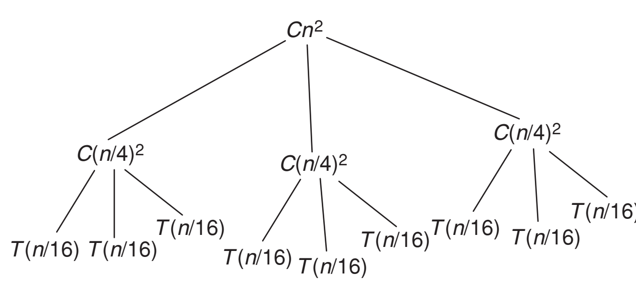


Figure 8 Recursion tree for $T(n) = 3T(n/4) + cn^2$

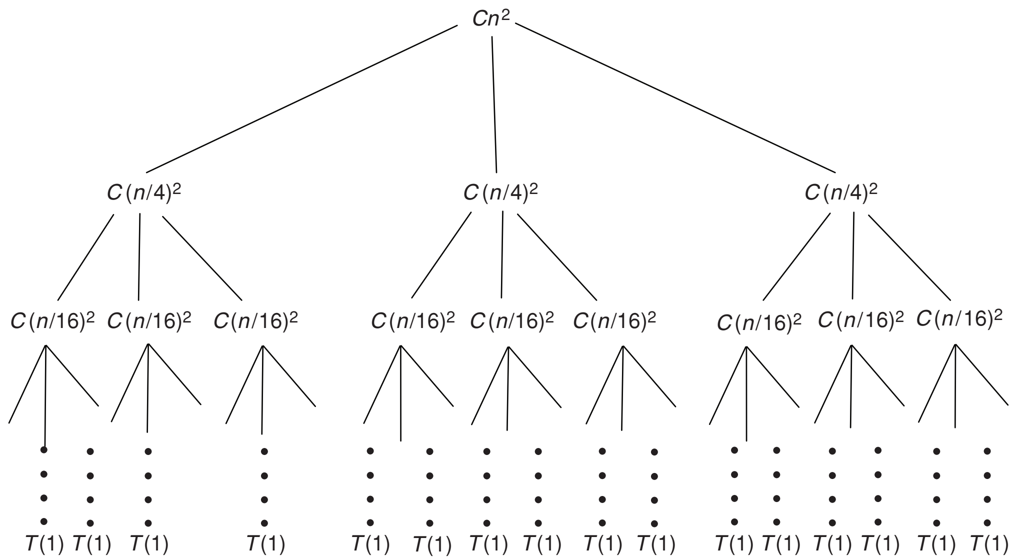

Figure 9 Expanded Recursion tree with height $\log_4^n$ ($\therefore$ levels $\log_4^n + 1$)

The sub-problem size for a node at depth 'i' is $n/4^i$, at this depth, the size of the sub-problem would be $n = 1$, when $n/4^i = 1$ or $i = \log_4^n$, the tree has $\log_4^{n+1}$ levels.

- We have to determine the cost at each level of the tree. Each level has 3 times more nodes than the level above, so the number of nodes at depth 'i' is 3^i.
- Sub problem sizes reduce by a factor of '4' for each level we go down from the root, each node at depth i, for $i = 0, 1, 2 \ldots \log_4^{n-1}$, has a cost of $c(n/4^i)^2$.

Total cost over all nodes at depth i, for $i = 0, 1, \ldots \log_4^{n-1}$

$$= 3^i * c\left(\frac{n}{4^i}\right)^2 = \left(\frac{3}{16}\right)^i cn^2$$

The last level, at depth $\log_4^n$ has 3^i nodes $= 3^{\log_4 n} = n^{\log_4 3}$ each contributing cost $T(1)$, for a total cost of $n^{\log_4 3}\, T(1)$, which is $\theta(n^{\log_4 3})$ cost of the entire tree is equal to sum of costs over all levels.

$$T(n) = cn^2 + \frac{3}{16}cn^2 + \left(\frac{3}{16}\right)^2 cn^2 + \cdots +$$

$$\left(\frac{3}{16}\right)^{\log_4^{n-1}} cn^2 + \cdots + \theta(n^{\log_4 3})$$

$$= \sum_{i=0}^{\log_4^{n-1}} \left(\frac{3}{16}\right)^i cn^2 + \theta(n^{\log_4 3})$$

$$< \sum_{i=0}^{\infty} \left(\frac{3}{16}\right)^i cn^2 + \theta(n^{\log_4 3})$$

$$= \frac{1}{1-\left(\frac{3}{16}\right)} cn^2 + \theta(n^{\log_4 3})$$

$$= \frac{16}{13}{}^2 cn + \theta(n^{\log_4 3}) = O(n^2)$$

Master Method

Let $a \geq 1$ and $b > 1$ be cons-tants, let $f(n)$ be a function and let $T(n)$ be defined on the non-negative integers by the recurrence

$$T(n) = aT(n/b) + f(n)$$

$T(n)$ can be bounded asymptotically as follows

1. If $f(n) = O(n^{\log_b a-\in})$ for some constant $\in > 0$, then $T(n) = \theta(n^{\log_b a})$
2. If $f(n) = \theta(n^{\log_b a})$ then $T(n) = \theta(n^{\log_b a}. \log n)$
3. If $f(n) = \Omega(n^{\log_b a+\in})$ for some constant $\in > 0$, and if $af(n/b) \leq cf(n)$ for some constant $c < 1$ and all sufficiently large n, then $T(n) = \theta(f(n))$.

Note: In the first case, not only must $f(n)$ be smaller than $n \log_b^a$, it must be polynomially smaller. That is, $f(n)$ must be asymptotically smaller than $n^{\log_b a}$ by a factor of $n^{\in}$, for some constant $\in > 0$.

In the third case, not only must $f(n)$ be larger than $n^{\log_b a}$, it must be polynomially larger and in addition satisfy the regularity condition $af(n/b) \leq Cf(n)$.

Example: Consider the given recurrence relation $T(n) = 9T(n/3) + n$.

To apply master theorem, the recurrence relation must be in the following form:

$$T(n) = aT(n/b) + f(n)$$

$$a = 9, b = 3, f(n) = n$$

$$n^{\log_b a} = n^{\log_3 9} = n^2$$

Since $f(n) = O(n^{\log_3 9-\in})$, where $\in = 1$

We can apply case 1 of the master theorem and the solution is $T(n) = \theta(n^2)$.

Exercises

Practice Problems 1

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. What is the time complexity of the recurrence relation $T(n) = 2T\left(\frac{n}{2}\right) + n^2$?
(A) $\theta(n^2)$ (B) $\theta(n)$
(C) $\theta(n^3)$ (D) $\theta(n \log n)$

2. What is the time complexity of the recurrence relation by using masters theorem $T(n) = 2T\left(\frac{n}{2}\right) + n$?
(A) $\theta(n^2)$ (B) $\theta(n)$
(C) $\theta(n^3)$ (D) $\theta(n \log n)$

3. What is the time complexity of the recurrence relation by using master theorem, $T(n) = 2T\left(\frac{n}{4}\right) + n^{0.51}$
(A) $\theta(n^2)$ (B) $\theta(n)$
(C) $\theta(n^3)$ (D) $(n^{0.51})$

4. What is the time complexity of the recurrence relation using master theorem, $T(n) = 7T\left(\frac{n}{3}\right) + n^2$?
(A) $\theta(n^2)$ (B) $\theta(n)$
(C) $\theta(n^3)$ (D) $(\log n)$

5. Time complexity of $f(x) = 4x^2 - 5x + 3$ is
(A) $O(x)$ (B) $O(x^2)$
(B) $O(x^{3/2})$ (D) $O(x^{0.5})$

6. Time complexity of $f(x) = (x^2 + 5 \log_2 x)/(2x + 1)$ is
(A) $O(x)$ (B) $O(x^2)$
(C) $O(x^{3/2})$ (D) $O(x^{0.5})$

7. For the recurrence relation, $T(n) = 2T(\lfloor \sqrt{n} \rfloor) + \lg n$, which is tightest upper bound?
(A) $T(n) = O(n^2)$ (B) $T(n) = O(n^3)$
(C) $T(n) = O(\log n)$ (D) $T(n) = O(\lg n \lg \lg n)$

8. Consider $T(n) = 9T(n/3) + n$, which of the following is TRUE?
(A) $T(n) = \theta(n^2)$ (B) $T(n) = \theta(n^3)$
(C) $T(n) = \Omega(n^3)$ (D) $T(n) = O(n)$

9. If $f(n)$ is $100 * n$ seconds and $g(n)$ is $0.5 * n$ seconds then
(A) $f(n) = g(n)$ (B) $f(n) = \Omega(g(n))$
(C) $f(n) = w(g(n))$ (D) None of these

10. Solve the recurrence relation using master method: $T(n) = 4T(n/2) + n^2$
(A) $\theta(n \log n)$ (B) $\theta(n^2 \log n)$
(C) $\theta(n^2)$ (D) $\theta(n^3)$

11. Arrange the following functions according to their order of growth (from low to high):
(A) $\sqrt[3]{n}, 0.001n^4 + 3n^3 + 1, 3^n, 2^{2n}$
(B) $3^n, 2^{2n}, \sqrt[3]{n}, 0.001n^4 + 3n^3 + 1$
(C) $2^{2n}, \sqrt[3]{n}, 3^n, 0.001n^4 + 3n^3 + 1$
(D) $\sqrt[3]{n}, 2^{2n}, 3^n, 0.001n^4 + 3n^3 + 1$

12. The following algorithm checks whether all the elements in a given array are distinct:

Input: array $A[0 \ldots n-1]$
Output: true (or) false
For $i \leftarrow 0$ to $n - 2$ do
For $j \leftarrow i + 1$ to $n - 1$ do
if $A[i] = A[j]$ return false
return true

The time complexity in worst case is
(A) $\theta(n^2)$ (B) $\theta(n)$
(C) $\theta(\log n)$ (D) $\theta(n \log n)$

13. The order of growth for the following recurrence relation is $T(n) = 4T(n/2) + n^3$, $T(1) = 1$
(A) $\theta(n)$ (B) $\theta(n^3)$
(C) $\theta(n^2)$ (D) $\theta(\log n)$

14. Time complexity of $T(n) = 2T\left(\frac{n}{4}\right) + \sqrt{3}$ is
(A) $\theta(\sqrt{n} \log n)$ (B) $\theta(\sqrt{n} \log \sqrt{n})$
(C) $\theta(\sqrt{n})$ (D) $\theta(n^2)$

15. Consider the following three claims
(I) $(n + k)^m = \theta(n^m)$, where k and m are constants
(II) $2^{n+1} = O(2^n)$
(III) $2^{2n+1} = O(2^n)$

Which one of the following is correct?
(A) I and III (B) I and II
(C) II and III (D) I, II and III

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Arrange the order of growth in ascending order:
(A) $O(1) > O(\log n) > O(n) > O(n^2)$
(B) $O(n) > O(1) > O(\log n) > O(n^2)$
(C) $O(\log n) > O(n) > O(1) > O(n^2)$
(D) $O(n^2) > O(n) > O(\log n) > O(1)$

2. $\sqrt{n} = \Omega(\log n)$ means
(A) To the least $\sqrt{n}$ is log n
(B) $\sqrt{n}$ is log n always
(C) $\sqrt{n}$ is at most log n
(D) None of these

3. Which of the following is correct?
(i) $\theta(g(n)) = O(g(n)) \cap \Omega(g(n))$
(ii) $\theta(g(n)) = O(g(n)) \cup \Omega(g(n))$

(A) (i) is true (ii) is false (B) Both are true
(C) Both are false (D) (ii) is true (i) is false

4. $2n^2 = x\,(n^3)$, x is which notation?
(A) Big-oh (B) Small-oh
(C) Ω – notation (D) θ – notation

5. Master method applies to recurrence of the form $T(n) = a\,T(n/b) + f(n)$ where
(A) $a \geq 1, b > 1$ (B) $a = 1, b > 1$
(C) $a > 1, b = 1$ (D) $a \geq 1, b \geq 1$

6. What is the time complexity of the recurrence relation using master method?

$$T(n) = 4T\left(\frac{n}{2}\right) + n$$

(A) $\theta(n^2)$ (B) $\theta(n)$
(C) $\theta(\log n)$ (D) $\theta(n \log n)$

7. Use the informal definitions of O, θ Ω to determine these assertions which of the following assertions are true.
(A) $n(n+1)/2 \in O(n^3)$ (B) $n(n+1)/2 \in O(n^2)$
(C) $n(n+1)/2 \in \Omega(n)$ (D) All the above

8. Match the following:

(i)	Big-oh	(A)	$\geq$
(ii)	Small-o	(B)	$\leq$
(iii)	Ω	(C)	$=$
(iv)	θ	(D)	$<$
(v)	ω	(E)	$>$

(A) (i) – D, (ii) – A, (iii) – C, (iv) –B , (v) – E
(B) (i) – B, (ii) – D, (iii) – A, (iv) – C, (v) – E
(C) (i) – C, (ii) – A, (iii) – B, (iv) – E, (v) – D
(D) (i) – A, (ii) – B, (iii) – C, (iv) – D, (v) – E

9. Which one of the following statements is true?
(A) Both time and space efficiencies are measured as functions of the algorithm input size.
(B) Only time efficiencies are measured as a function of the algorithm input size.
(C) Only space efficiencies are measured as a function of the algorithm input size.
(D) Neither space nor time efficiencies are measured as a function of the algorithm input size.

10. Which of the following is true?
(A) Investigation of the average case efficiency is considerably more difficult than investigation of the worst case and best case efficiencies.
(B) Investigation of best case is more complex than average case.
(C) Investigation of worst case is more complex than average case.
(D) None of these

11. Time complexity of $T(n) = T(n/3) + T(2n/3) + O(n)$ is
(A) $O(1)$
(B) $O(n \log n)$
(C) $O(\log n)$
(D) $O(n^2)$

12. Solve the recurrence relation to find $T(n)$: $T(n) = 4(n/2) + n$
(A) $\theta(n^2)$ (B) $\theta(\log_2 n)$
(C) $\theta(n^2 \log_2 n)$ (D) $\theta(n^3)$

13. What is the worst case analysis for the given code?

```
int search (int a[ ], int x, int n)
{
int i;
for (i = 0 ; i < n; i ++)
if (a [i] = = x)
return i;
return -1;
}
```

(A) $O(n)$ (B) $O(n \log n)$
(C) $O(\log n)$ (D) $O(n^2)$

14. Find the time complexity of the given code.

```
void f (int n)
{
if (n > 0)
{
f (n/2);
f (n/2);
}
}
```

(A) $\theta(n^2)$
(B) $\theta(n)$
(C) $\theta(n \log n)$
(D) $\theta(2^n)$

15. The running time of the following algorithm procedure
$A(n)$
if $n \leq 2$
return (1)
else
return $(A(\sqrt{n}))$
is described by

(A) $O(\sqrt{n} \log n)$
(B) $O(\log n)$
(C) $O(\log \log n)$
(D) $O(n)$

Previous Years' Questions

1. The median of n elements can be found in $O(n)$ time. Which one of the following is correct about the complexity of quick sort, in which median is selected as pivot? **[2006]**

(A) $\theta(n)$ (B) $\theta(n \log n)$
(C) $\theta(n^2)$ (D) $\theta(n^3)$

2. Given two arrays of numbers $a_1 \dots a_n$ and $b_1 \dots b_n$ where each number is 0 or 1, the fastest algorithm to find the largest span (i, j) such that $a_i + a_i + 1 + \dots + a_j = b_i + b_i + 1 + \dots + b_j$, or report that there is not such span, **[2006]**

(A) Takes $O(3^n)$ and $\Omega(2^n)$ time if hashing is permitted
(B) Takes $O(n^3)$ and $\Omega(n^{2.5})$ time in the key comparison model
(C) Takes $\Theta(n)$ time and space
(D) Takes $O(\sqrt{n})$ time only if the sum of the $2n$ elements is an even number

3. Consider the following segment of C-code:

```
int j, n;
    j = 1;
    while (j <=n)
j = j*2;
```

The number of comparisons made in the execution of the loop for any $n > 0$ is: **[2007]**

(A) $\lceil \log_2 n \rceil + 1$ (B) n
(C) $\lceil \log_2 + n \rceil$ (D) $\lfloor \log_2 n \rfloor + 1$

4. In the following C function, let $n \geq m$.

```
int gcd(n,m)
{
if (n%m = =0) return m;
      n = n%m;
return gcd(m,n);
}
```

How many recursive calls are made by this function? **[2007]**

(A) $\Theta(\log_2 n)$ (B) $\Omega(n)$
(C) $\Theta(\log_2 \log_2 n)$ (D) $\Theta(\sqrt{n})$

5. What is the time *complexity* of the following recursive function:

```
int DoSomething (int n) {
if (n <= 2)
    return 1;
  else
return(DoSomething (floor(sqrt(n)))+ n);}
```
[2007]

(A) $\Theta(n^2)$ (B) $\Theta(n \log_2 n)$
(C) $\Theta(\log_2 n)$ (D) $\Theta(\log_2 \log_2 n)$

6. An array of n numbers is given, where n is an even number. The maximum as well as the minimum of these n numbers needs to be determined. Which of the following is TRUE about the number of comparisons needed? **[2007]**

(A) At least $2n - c$ comparisons, for some constant c, are needed.
(B) At most $1.5n - 2$ comparisons are needed.
(C) At least $n \log_2 n$ comparisons are needed.
(D) None of the above.

7. Consider the following C code segment:

```
int IsPrime(n)
    {
    int i,n;
    for(i=2; i<= sqrt(n); i ++)
      if(n%i = =0)
       {printf("Not Prime\n"); return 0;}
    return 1;
}
```

Let $T(n)$ denote the number of times the *for* loop is executed by the program on input n. Which of the following is TRUE? **[2007]**

(A) $T(n) = O(\sqrt{n})$ and $T(n) = \Omega(\sqrt{n})$
(B) $T(n) = O(\sqrt{n})$ and $T(n) = \Omega(1)$
(C) $T(n) = O(n)$ and $T(n) = \Omega(\sqrt{n})$
(D) None of the above

8. The most efficient algorithm for finding the number of connected components in an undirected graph on n vertices and m edges has time complexity **[2008]**

(A) $\Theta(n)$ (B) $\Theta(m)$
(C) $\Theta(m + n)$ (D) $\Theta(mn)$

9. Consider the following functions:

$f(n) = 2^n$
$g(n) = n!$
$h(n) = n^{\log n}$

Which of the following statements about the asymptotic behavior of $f(n)$, $g(n)$, and $h(n)$ is true? **[2008]**

(A) $f(n) = O(g(n))$; $g(n) = O(h(n))$
(B) $f(n) = \Omega(g(n))$; $g(n) = O(h(n))$
(C) $g(n) = O(f(n))$; $h(n) = O(f(n))$
(D) $h(n) = O(f(n))$; $g(n) = \Omega(f(n))$

10. The minimum number of comparisons required to determine if an integer appears more than $n/2$ times in a sorted array of n integers is **[2008]**

(A) $\Theta(n)$ (B) $\Theta(\log n)$
(C) $\Theta(\log * n)$ (D) $\Theta(1)$

11. We have a binary heap on n elements and wish to insert n more elements (not necessarily one after another) into this heap. The total time required for this is **[2008]**

(A) $\Theta(\log n)$ (B) $\Theta(n)$
(C) $\Theta(n \log n)$ (D) $\Theta(n^2)$

12. The running time of an algorithm is represented by the following recurrence relation: **[2009]**

$$T(n) = \begin{cases} n & n \le 3 \\ T\left(\dfrac{n}{3}\right) + \text{cn} & \text{otherwise} \end{cases}$$

Which one of the following represents the time complexity of the algorithm?

(A) $\theta(n)$ (B) $\theta(n \log n)$
(C) $\theta(n^2)$ (D) $\theta(n^2 \log n)$

13. Two alternative packages A and B are available for processing a database having 10^k records. Package A requires $0.0001\ n^2$ time units and package B requires $10n \log_{10} n$ time units to process n records. What is the smallest value of k for which package B will be preferred over A? **[2010]**

(A) 12 (B) 10
(C) 6 (D) 5

14. An algorithm to find the length of the longest monotonically increasing sequence of numbers in an array $A[0 : n - 1]$ is given below.

Let L denote the length of the longest monotonically increasing sequence starting at index in the array.

Initialize $L_{n-1} = 1$,

For all i such that $0 \le i \le n-2$

$Li \{= 1 + L_{i+1}$, if $A[i] < A\ [i + 1]$,

1 otherwise

Finally the length of the longest monotonically increasing sequence is Max $(L_0, L_1, \ldots L_{n-1})$

Which of the following statements is TRUE? **[2011]**

(A) The algorithm uses dynamic programming paradigm.
(B) The algorithm has a linear complexity and uses branch and bound paradigm.
(C) The algorithm has a non-linear polynomial complexity and uses branch and bound paradigm.
(D) The algorithm uses divide and conquer paradigm.

15. Which of the given options provides the increasing order of asymptotic complexity of functions f_1, f_2, f_3 and f_4? **[2011]**

$f_1(n) = 2^n$

$f_2(n) = n^{3/2}$

$f_3(n) = n \log_2 n$

$f_4(n) = n^{\log_2 n}$

(A) f_3, f_2, f_4, f_1 (B) f_3, f_2, f_1, f_4
(C) f_2, f_3, f_1, f_4 (D) f_2, f_3, f_4, f_1

16. Let $W(n)$ and $A(n)$ denote respectively, the worst-case and average-case running time of an algorithm executed on input of size n. Which of the following is **ALWAYS TRUE**? **[2012]**

(A) $A(n) = \Omega(W(n))$ (B) $A(n) = \Theta(W(n))$
(C) $A(n) = O(W(n))$ (D) $A(n) = o(W(n))$

17. The recurrence relation capturing the optimal execution time of the Towers of Hanoi problem with n discs is **[2012]**

(A) $T(n) = 2T(n - 2) + 2$
(B) $T(n) = 2T(n - 1) + n$
(C) $T(n) = 2T(n/2) + 1$
(D) $T(n) = 2T(n - 1) + 1$

18. A list of n strings, each of length n, is sorted into lexicographic order using the merge sort algorithm. The worst-case running time of this computation is **[2012]**

(A) $O(n \log n)$ (B) $O(n^2 \log n)$
(C) $O(n^2 + \log n)$ (D) $O(n^2)$

19. Consider the following function:

```
int unknown (int n) {
    int i, j, k = 0;
    for (i = n/2; i < = n; i++)
            for (j = 2; j < = n; j = j*2)
                    k = k + n/2;
return (k);
}
```

The return value of the function is **[2013]**

(A) $\Theta(n^2)$ (B) $\Theta(n^2 \log n)$
(C) $\Theta(n^3)$ (D) $\Theta(n^3 \log n)$

20. The number of elements that can be sorted in $\Theta(\log n)$ time using heap sort is **[2013]**

(A) $\Theta(1)$

(B) $\Theta(\sqrt{\log n})$

(C) $\Theta\left(\dfrac{\log n}{\log \log n}\right)$

(D) $\Theta(\log n)$

21. Which one of the following correctly determines the solution of the recurrence relation with $T(1) = 1$

$T(n) = 2T\left(\dfrac{n}{2}\right) + \log n$? **[2014]**

(A) $\theta(n)$ (B) $\theta(n \log n)$
(C) $\theta(n^2)$ (D) $\theta(\log n)$

22. An algorithm performs $(\log N)^{1/2}$ find operations, N insert operations, $(\log N)^{1/2}$ delete operations, and $(\log N)^{1/2}$ decrease-key operations on a set of data items with keys drawn from a linearly ordered set. For a delete operation, a pointer is provided to the record that must be deleted For the decrease – key operation, a pointer is provided to the record that has its key decreased Which one of the following data structures is the most suited for the algorithm to use, if the

goal is to achieve the best total asymptotic complexity considering all the operations? **[2015]**
(A) Unsorted array
(B) Min-heap
(C) Sorted array
(D) Sorted doubly linked list

23. Consider the following C function.

```
int fun1(int n) {
   int i, j, k, p, q=0;
   for (i=1; i<n; ++i) {
         p=0;
         for (j=n; j>1; j=j/2)
               ++p;
         for (k=1; k<p; k=k*2)
               ++q;
         }
         return q;
   }
```

Which one of the following most closely approximates the return value of the function fun1? **[2015]**
(A) n^3 (B) $n(\log n)^2$
(C) $n \log n$ (D) $n \log(\log n)$

24. An unordered list contains n distinct elements. The number of comparisons to find an element in this list that is neither maximum nor minimum is **[2015]**
(A) $\theta(n \log n)$ (B) $\theta(n)$
(C) $\theta(\log n)$ (D) $\theta(1)$

25. Consider a complete binary tree where the left and the right subtrees of the root are max-heaps. The lower bound for the number of operations to convert the tree to a heap is **[2015]**
(A) $\Omega(\log n)$ (B) $\Omega(n)$
(C) $\Omega(n \log n)$ (D) $\Omega(n^2)$

26. Consider the equality $\sum_{i=0}^{n} i^3 =$ and the following choices for X
1. $\theta(n^4)$
2. $\theta(n^5)$
3. $O(n^5)$
4. $\Omega(n^3)$

The equality above remains correct if X is replaced by **[2015]**
(A) Only 1
(B) Only 2
(C) 1 or 3 or 4 but not 2
(D) 2 or 3 or 4 but not 1

27. Consider the following array of elements
<89, 19, 50, 17, 12, 15, 2, 5, 7, 11, 6, 9, 100>
The minimum number of interchanges needed to convert it into a max-heap is **[2015]**
(A) 4 (B) 5
(C) 2 (D) 3

28. Let $f(n) = n$ and $g(n) = n^{(1 + \sin n)}$, where n is a positive integer. Which of the following statements is/are correct? **[2015]**
I. $f(n) = O(g(n))$
II. $f(n) = \Omega(g(n))$
(A) Only I (B) Only II
(C) Both I and II (D) Neither I nor II

29. A queue is implemented using an array such that ENQUEUE and DEQUEUE operations are performed efficiently. Which one of the following statements is **CORRECT** (n refers to the number of items in the queue)? **[2016]**
(A) Both operations can be performed in O(1) time.
(B) At most one operation can be performed in O(1) time but the worst case time for the other operation will be Ω (n).
(C) The worst case time complexity for both operations will be Ω (n).
(D) Worst case time complexity for both operations will be Ω (logn).

30. Consider a carry look ahead adder for adding two n - bit integers, built using gates of fan - in at most two. The time to perform addition using this adder is **[2016]**
(A) $\Theta(1)$ (B) $\Theta(\log(n))$
(C) $\Theta\left(\sqrt{n}\right)$ (D) $\Theta(n)$

31. N items are stored in a sorted doubly linked list. For a *delete* operation, a pointer is provided to the record to be deleted. For a *decrease - key* operation, a pointer is provided to the record on which the operation is to be performed.

An algorithm performs the following operations on the list in this order: Θ (N) *delete*, O (logN) *insert*, O (log N) *find*, and Θ (N) *decrease - key*. What is the time complexity of all these operations put together? **[2016]**
(A) $O(\log^2 N)$ (B) O(N)
(C) $O(N^2)$ (D) $\Theta(N^2 \log N)$

32. In an adjacency list representation of an undirected simple graph G = (V,E), each edge *(u,v)* has two adjacency list entries:*[v]* in the adjacency list of u, and *[u]* in the adjacency list of v. These are called twins of each other. A twin pointer is a pointer from an adjacency list entry to its twin. If $|E| = m$ and $|V| = n$, and the memory size is not a constraint, what is the time complexity of the most efficient algorithm to set the twin pointer in each entry in each adjacency list? **[2016]**
(A) $\Theta(n^2)$ (B) $\Theta(n + m)$
(C) $\Theta(m^2)$ (D) $\Theta(n^4)$

33. Consider the following functions from positive integers to real numbers:

$$10,\ \sqrt{n},\ n,\ \log_2 n,\ \frac{100}{n}.$$

The CORRECT arrangement of the above functions in increasing order of asymptotic complexity is: **[2017]**

(A) $\log_2 n, \frac{100}{n}, 10, \sqrt{n}, n$

(B) $\frac{100}{n}, 10, \log_2 n, \sqrt{n}, n$

(C) $10, \frac{100}{n}, \sqrt{n}, \log_2 n, n$

(D) $\frac{100}{n}, \log_2 n, 10, \sqrt{n}, n$

34. Consider the recurrence function

$$T(n) = \begin{cases} 2T\left(\sqrt{n}\right)+1 & n > 2 \\ 2, & 0 < n \leq 2 \end{cases}$$

Then $T(n)$ in terms of Θ notation is **[2017]**

(A) $\Theta(\log \log n)$ (B) $\Theta(\log n)$

(C) $\Theta\left(\sqrt{n}\right)$ (D) $\Theta(n)$

35. Consider the following C function.

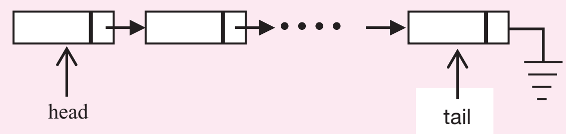
```
int fun (int n)   {
        int i, j;
        for(i = 1; i <= n; i++)   {
               for (j = 1; j < n; j += i) {
                      printf{" %d %d",i, j);
                      }
               }
}
```

Time complexity of fun in terms of Θ notation is **[2017]**

(A) $\Theta\left(n\sqrt{n}\right)$ (B) $\Theta(n^2)$

(C) $\Theta(n \log n)$ (D) $\Theta(n^2 \log n)$

36. A queue is implemented using a non-circular singly linked list. The queue has a head pointer and a tail pointer, as shown in the figure. Let n denote the number of nodes in the queue. Let enqueue be implemented by inserting a new node at the head, and dequeue be implemented by deletion of a node from the tail.



Which one of the following is the time complexity of the most time-efficient implementation of enqueue and dequeue, respectively, for this data structure? **[2018]**

(A) $\theta(1), \theta(1)$ (B) $\theta(1), \theta(n)$

(C) $\theta(n), \theta(1)$ (D) $\theta(n), \theta(n)$

37. Consider the following C code. Assume that unsigned long int type length is 64 bits.

```
unsigned long int fun (unsigned long int n) {
unsigned long int i, j = 0, sum = 0;
for (i = n; i > 1. i = i/2) j++;
for (; j > 1; j = j/2) sum++;
return (sum);
}
```

The value returned when we call fun with the input 2^{40} is: **[2018]**

(A) 4 (B) 5

(C) 6 (D) 40

Chapter 2

Sorting Algorithms

LEARNING OBJECTIVES

- *Sorting algorithms*
- *Merge sort*
- *Bubble sort*
- *Insertion sort*
- *Selection sort*
- *Selection sort algorithm*
- *Binary search trees*
- *Heap sort*
- *Sorting–performing delete max operations*
- *Max-heap property*
- *Min-heap property*
- *Priority queues*

Sorting Algorithms

Purpose of sorting

Sorting is a technique which reduces problem complexity and search complexity.

- Insertion sort takes $\theta(n^2)$ time in the worst case. It is a fast inplace sorting algorithm for small input sizes.
- Merge sort has a better asymptotic running time $\theta(n \log n)$, but it does not operate in inplace.
- Heap sort, sorts 'n' numbers inplace in $\theta(n \log n)$ time, it uses a data structure called heap, with which we can also implement a priority queue.
- Quick sort also sorts 'n' numbers in place, but its worst – case running time is $\theta(n^2)$. Its average case is $\theta(n \log n)$. The constant factor in quick sort's running time is small, This algorithm performs better for large input arrays.
- Insertion sort, merge sort, heap sort, and quick sort are all comparison based sorts; they determine the sorted order of an inputarray by comparing elements.
- We can beat the lower bound of Ω ($n \log n$) if we can gather information about the sorted order of the input by means other than comparing elements.
- The counting sort algorithm, assumes that the input numbers are in the set $\{1, 2, \ldots. k\}$. By using array indexing as a tool for determining relative order, counting sort can sort n numbers in $\theta(k + n)$ time. Thus counting sort runs in time that is linear in size of the input array.
- Radix sort can be used to extend the range of counting sort. If there are 'n' integers to sort, each integer has 'd' digits, and each digit is in the set $\{1, 2,\ldots k\}$, then radix sort can sort the numbers in $\theta(d\,(n + k))$ time. Where 'd' is constant. Radix sort runs in linear time.
- Bucket sort, requires knowledge of the probabilistic distribution of numbers in the input array.

Merge Sort

Suppose that our division of the problem yields 'a' sub problems, each of which is $\left(\frac{1}{b}\right)$th size of the original problem. For merge sort, both a and b are 2, but sometimes $a \neq b$. If we take $D(n)$ time to divide the problem into sub problems and $C(n)$ time to combine the solutions of the sub problems into the solution to the original problem. The recurrence relation for merge sort is

$$T(n) = \begin{cases} \theta(1) \text{ if } n \leq \mathrm{c}, \\ aT(n/b) + D(n) + C(n) \text{ otherwise} \end{cases}$$

Running time is broken down as follows:

Divide: This step computes the middle of the sub array, which takes constant time $\theta(1)$.

Conquer: We solve 2 sub problems of size $(n/2)$ each recursively which takes $2T(n/2)$ time.

Combine: Merge sort procedure on an n-element sub array takes time $\theta(n)$.

- Worst case running time $T(n)$ of merge sort

$$T(n) = \begin{cases} 0(1) \text{ if } & n \le 1 \\ aT(n/2) + \theta(n) \text{ if } & n > 1 \end{cases}$$

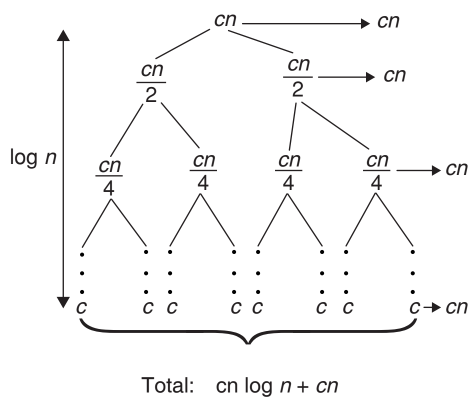

Figure 1 Recurrence tree

The top level has total cost 'cn', the next level has total cost $c(n/2) + c(n/2) = cn$ and the next level has total cost $c(n/4) + c(n/4) + c(n/4) + c(n/4) = cn$ and so on. The ith level has total cost $2^i\ c\ (n/2^i) = cn$. At the bottom level, there are 'n' nodes, each contributing a cost of c, for a total cost of 'cn'. The total number of levels of the 'recursion tree' is $\log n + 1$.

There are $\log n + 1$ levels, each costing cn, for a total cost of $cn\ (\log n + 1) = cn \log n + cn$ ignoring the low–order term and the constant c, gives the desired result of $\theta(n \log n)$.

Bubble Sort

Bubble sort is a simple sorting algorithm that works by repeatedly stepping through the list to be sorted, comparing each pair of adjacent items, and swapping them if they are in the wrong order. The pass through the list is repeated until no swaps are needed, which indicates that the list is sorted. The algorithm gets its name from the way smaller elements 'bubble' to the top of the list.

Example: Take the array of numbers '5 1 4 2 8'and sort the array from lowest number to greatest number using bubble sort algorithm. In each step, elements underlined are being compared.

First pass:

$(\underline{5\ \ 1}\ \ 4\ \ 2\ \ 8) \to (1\ \ 5\ \ 4\ \ 2\ \ 8)$, here algorithm compares the first 2 elements and swaps them

$(1\ \ \underline{5\ \ 4}\ \ 2\ \ 8) \to (1\ \ 4\ \ 5\ \ 2\ \ 8)$, swap $(5 > 4)$

$(1\ \ 4\ \ \underline{5\ \ 2}\ \ 8) \to (1\ \ 4\ \ 2\ \ 5\ \ 8)$, swap $(5 > 2)$

$(1\ \ 4\ \ 2\ \ \underline{5\ \ 8}) \to (1\ \ 4\ \ 2\ \ 5\ \ 8)$, since these elements are already in order, algorithm does not swap them.

Second pass:

$(\underline{1\ \ 4}\ \ 2\ \ 5\ \ 8) \to (1\ \ 4\ \ 2\ \ 5\ \ 8)$

$(1\ \ \underline{4\ \ 2}\ \ 5\ \ 8) \to (1\ \ 2\ \ 4\ \ 5\ \ 8)$, swap since $(4 > 2)$

$(1\ \ 2\ \ \underline{4\ \ 5}\ \ 8) \to (1\ \ 2\ \ 4\ \ 5\ \ 8)$

$(1\ \ 2\ \ 4\ \ \underline{5\ \ 8}) \to (1\ \ 2\ \ 4\ \ 5\ \ 8)$

The array is already sorted, but our algorithm does not know if it is completed. The algorithm needs one whole pass without any swap to know it is sorted.

Third pass:

$(\underline{1\ \ 2}\ \ 4\ \ 5\ \ 8) \to (1\ \ 2\ \ 4\ \ 5\ \ 8)$

$(1\ \ \underline{2\ \ 4}\ \ 5\ \ 8) \to (1\ \ 2\ \ 4\ \ 5\ \ 8)$

$(1\ \ 2\ \ \underline{4\ \ 5}\ \ 8) \to (1\ \ 2\ \ 4\ \ 5\ \ 8)$

$(1\ \ 2\ \ 4\ \ \underline{5\ \ 8}) \to (1\ \ 2\ \ 4\ \ 5\ \ 8)$

Finally the array is sorted, and the algorithm can terminate.

Algorithm

```
void bubblesort (int a [ ], int n)
{
  int i, j, temp;
  for (i=0; i < n-1; i++)
  {
    for (j=0; j < n − 1 − i; j++)
    if (a [j] > a [j + 1])
    {
      temp = a [j + 1];
      a [j + 1] = a [j];
      a [j] = temp;
    }
  }
}
```

Insertion Sort

Insertion sort is a comparison sort in which the sorted array is built one entry at a time. It is much less efficient on large lists than more advanced algorithms such a quick sort, heap sort, (or) merge sort. Insertion sort provides several advantages.

- Efficient for small data sets.
- Adaptive, i.e., efficient for data set that are already substantially sorted. The complexity is $O(n + d)$, where d is the number of inversions.
- More efficient in practice than most other simple quadratic, i.e., $O(n^2)$ algorithms such as selection sort (or) bubble sort, the best case is $O(n)$.
- Stable, i.e., does not change the relative order of elements with equal keys.
- In-place i.e., only requires a constant amount $O(1)$ of additional memory space.
- Online, i.e., can sort a list as it receives it.

Algorithm

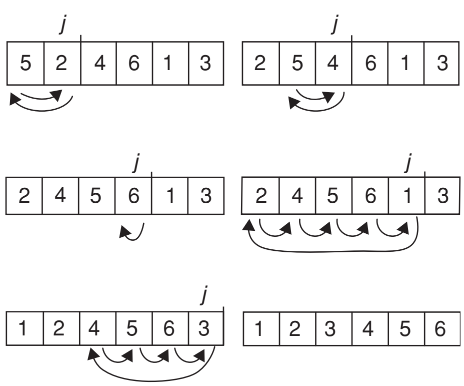
```
Insertion sort (A)
For (j ← 2) to length [A]
Do key ← A [j]
i ←j - 1;
While i > 0 and A [i] > key
{
Do A [i + 1] ← A [i]
i ← i - 1
}
A [i + 1] ← key
```

Every repetition of insertion sort removes an element from the input data, inserting it into the correct position in the already sorted list, until no input element remains. Sorting is typically done in–place. The resulting array after K iterations has the property where the first $k + 1$ entries are sorted. In each iteration the first remaining entry of the input is removed, inserted into the result at the correct position, with each element greater than X copied to the right as it is compared against. X.

Performance

- The best case input is an array that is already sorted. In this case insertion sort has a linear running time (i.e., $\theta(n)$).
- The worst case input is an array sorted in reverse order. In this case every iteration of the inner loop will scan and shift the entire sorted subsection of the array before inserting the next element. For this case insertion sort has a quadratic running time ($O(n^2)$).
- The average case is also quadratic, which makes insertion sort impractical for sorting large arrays, however, insertion sort is one of the fastest algorithms for sorting very small arrays even faster than quick sort.

Example: Following figure shows the operation of insertion sort on the array $A = (5, 2, 4, 6, 1, 3)$. Each part shows what happens for a particular iteration with the value of j indicated. j indexes the 'Current card' being inserted.



Read the figure row by row. Elements to the left of $A[j]$ that are greater than $A[j]$ move one position to the right and $A[j]$ moves into the evacuated position.

Selection Sort

Selection sort is a sorting algorithm, specifically an in-place comparison sort. It has $O(n^2)$ complexity, making it inefficient on large lists.
The algorithm works as follows:

1. Find the minimum value in the list.
2. Swap it with the value in the first position.
3. Repeat the steps above for the remainder of the list (starting at the second position and advancing each time).

Analysis

Selection sort is not difficult to analyze compared to other sorting algorithms, since none of the loops depend on the data in the array selecting the lowest element requires scanning all n elements (this takes $n - 1$ comparisons) and then swapping it into the first position. Finding the next lowest element requires scanning the remaining $n - 1$ elements and so on, for $(n - 1) + (n - 2) + \cdots + 2 + 1 = n(n - 1)/2 \in \theta(n^2)$ comparisons.

Each of these scans requires one swap for $n - 1$ elements (the final element is already in place).

Selection sort Algorithm

First, the minimum value in the list is found. Then, the first element (with an index of 0) is swapped with this value. Lastly, the steps mentioned are repeated for rest of the array (starting at the 2nd position).

Example 1: Here's a step by step example to illustrate the selection sort algorithm using numbers.

Original array: 6 3 5 4 9 2 7
1st pass $\rightarrow$ 2 3 5 4 9 6 7 (2 and 6 were swapped)
2nd pass $\rightarrow$ 2 3 5 4 9 6 7 (no swap)
3rd pass $\rightarrow$ 2 3 4 5 9 6 7 (4 and 5 were swapped)
4th pass $\rightarrow$ 2 3 4 5 6 9 7 (6 and 9 were swapped)
5th pass $\rightarrow$ 2 3 4 5 6 7 9 (7 and 9 were swapped)
6th pass $\rightarrow$ 2 3 4 5 6 7 9 (no swap)

Note: There are 7 keys in the list and thus 6 passes were required. However, only 4 swaps took place.

Example 2: Original array: LU, KU, HU, LO, SU, PU
1st pass $\rightarrow$ HU, KU, LU, LO, SU, PU
2nd pass $\rightarrow$ HU, KU, LU, LO, SU, PU
3rd pass $\rightarrow$ HU, KU, LO, LU, SU, PU
4th pass $\rightarrow$ HU, KU, LO, LU, SU, PU
5th pass $\rightarrow$ HU, KU, LO, LU, PU, SU

Note: There were 6 elements in the list and thus 5 passes were required. However, only 3 swaps took place.

Binary Search Trees

Search trees are data structures that support many dynamic, set operations, including SEARCH, MINIMUM, MAXIMUM, PREDECESSOR, SUCCESSOR, INSERT and DELETE. A search tree can be used as a dictionary and as a priority Queue. Operations on a binary search tree take time proportional to the height of the tree. For a complete binary tree with 'n' nodes, basic operations run in $\theta(\log n)$ worst-case time. If the tree is a linear chain of 'n' nodes, the basic operations take $\theta(n)$ worst-case time.

A binary search tree is organized, in a binary tree such a tree can be represented by a linked data structure in which each node is an object. In addition to key field, each node contains fields left, right and P that point to the nodes corresponding to its left child, its right child, and its parent,

respectively. If the child (or) parent is missing, the appropriate field contains the value NIL. The root node is the only node in the tree whose parent field is NIL.

Binary search tree property

The keys in a binary search tree are always stored in such a way as to satisfy the binary search tree property.

Let 'a' be a node in a binary search tree. If 'b' is a node in the left sub tree of 'a', key $[b] \leq$ key $[a]$

If 'b' is a node in the right sub tree of 'a' then key $[a] \leq$ key $[b]$.

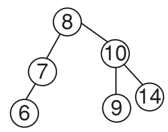


Figure 2 Binary search tree.

The binary search tree property allows us to print out all keys in a binary search tree in sorted order by a simple recursive algorithm called an inorder tree.

Algorithm

INORDER-TREE-WALK (root $[T]$)

INORDER-TREE-WALK (a)

1. If $a \neq$ NIL
2. Then INORDER-TREE-WALK (left $[a]$)
3. Print key $[a]$
4. INORDER-TREE-WALK (right $[a]$)

It takes $\theta(n)$ time to walk an n-node binary search tree, since after the initial call, the procedure is called recursively twice for each node in the tree.

Let $T(n)$ denote the time taken by IN-ORDER-TREE-WALK, when it is called on the root of an n-node subtree.

INORDER-TREE-WALK takes a small, constant amount of time on an empty sub-tree (for the test $x \neq$ NIL).

So $T(1) = C$ for some positive constant C.

For $n > 0$, suppose that INORDER-TREE-WALK is called on a node 'a' whose left subtree has k nodes and whose right subtree has $n - k - 1$ nodes.

The time to perform in order traversal is $T(n) = T(k) + T(n - k - 1) + d$.

For some positive constant 'd' that reflects the time to execute in-order (a), exclusive of the time spent in recursive calls $T(n) = (c + d)\, n + c$.

For $n = 0$, we have $(c + d)\, 0 + c = T(0)$,

For $n > 0$,

$$\begin{aligned} T(n) &= T(k) + T(n - k - 1) + d \\ &= ((c + d)(k + c) + ((c + d)\,(n - k - 1) + c) + d \\ &= (c + d)\, n + c - (c + d) + c + d = (c + d)n + c \end{aligned}$$

Heap Sort

Heap sort begins by building a heap out of the data set, and then removing the largest item and placing it at the end of the partially sorted array. After removing the largest item, it reconstructs heap, removes the largest remaining item, and places, it in the next open position from the end of the partially sorted array. This is repeated until there are no items left in the heap and the sorted array is full. Elementary implementations require two arrays one to hold the heap and the other to hold the sorted elements.

- Heap sort inserts the input list elements into a binary heap data structure. The largest value (in a max-heap) or the smallest value (in a min-heap) is extracted until none remain, the value having been extracted in sorted order.

Example: Given an array of 6 elements: 15, 19, 10, 7, 17, 16, sort them in ascending order using heap sort.

Steps:

1. Consider the values of the elements as priorities and build the heap tree.
2. Start delete Max operations, storing each deleted element at the end of the heap array.

If we want the elements to be sorted in ascending order, we need to build the heap tree in descending order-the greatest element will have the highest priority.

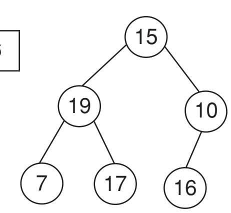
1. Note that we use only array, treating its parts differently,
2. When building the heap-tree, part of the array will be considered as the heap, and the rest part-the original array.
3. When sorting, part of the array will be the heap and the rest part-the sorted array.

Here is the array: 15, 19, 10, 7, 17, 6.

Building the Heap Tree

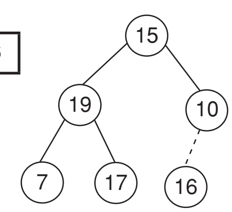
The array represented as a tree, which is complete but not ordered.

15	19	10	7	17	16



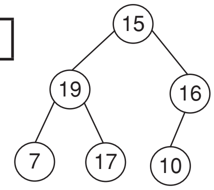
Start with the right most node at height 1 – the node at position 3 = size/2. It has one greater child and has to be percolated down.

15	19	10	7	17	16



After processing array [3] the situation is:

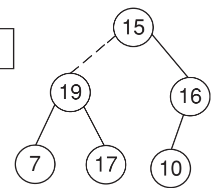
15	19	16	7	17	10



Next comes array [2]. Its children are smaller, so no percolation is needed.

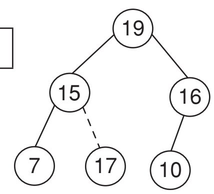
The last node to be processed is array[1]. Its left child is the greater of the children. The item at array [1] has to be percolated down to the left, swapped with array [2].

15	19	16	7	17	10



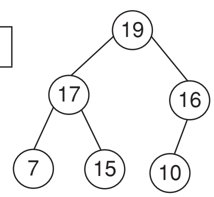
As a result:

19	15	16	7	17	10



The children of array [2] are greater and item 15 has to be moved down further, swapped with array [5].

19	17	16	7	15	10



Now the tree is ordered, and the binary heap is built.

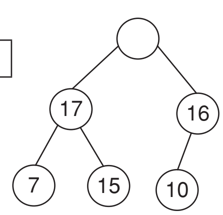
Sorting-performing Delete Max Operations

Delete the top element

Store 19 in a temporary place, a hole is created at the top.

	17	16	7	15	10

19



Swap 19 with the last element of the heap. As 10 will be adjusted in the heap, its cell will no longer be a part of the heap. Instead it becomes a cell from the sorted array

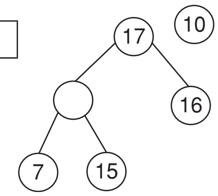
	17	16	7	15	19

10

Percolate down the hole

17		16	7	15	19

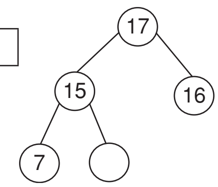
10



Percolate once more (10 is less than 15, so it cannot be inserted in the previous hole)

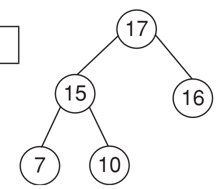
17	15	16	7		19

10



Now 10 can be inserted in the hole

17	15	16	7	10	19



Repeat the step *B* till the array is sorted.

Heap sort analysis

Heap sort uses a data structure called (binary) heap binary, heap is viewed as a complete binary tree. An Array A that represents a heap is an object with 2 attributes: length [*A*], which is the number of elements in the array and heap size [*A*], the number of elements in the heap stored within array *A*.

No element past *A* [heap size [*A*]], where heap size [*A*] ≤ length [*A*], is an element of the heap.

There are 2 kinds of binary heaps:

1. Max-heaps
2. Min-heaps

In both kinds the values in the nodes satisfy a heap-property.

Max-heap property *A*[PARENT (i)] ≥*A*[*i*]
The value of a node is almost the value of its parent. Thus the largest element in a max-heap is stored at the root, and the sub tree rooted at a node contains values no larger than that contained at the node itself.

Min-heap property For every mode '*i*' other than the root [PARENT (i)] ≤ *A*[*i*]. The smallest element in a min-heap is at the root.

Max-heaps are used in heap sort algorithm.
Min-heaps are commonly used in priority queues.

Basic operations on heaps run in time almost proportional to the height of the tree and thus take $O(\log n)$ time

- MAX-HEAPIFY procedure, runs in $O(\log n)$ time.
- BUILD-MAX-HEAP procedure, runs in linear time.
- HEAP SORT procedure, runs in $O(n \log n)$ time, sorts an array in place.
- MAX-HEAP-INSERT
  HEAP- EXTRACT-MAX
  HEAP-INCREASE-KEY
  HEAP-MAXIMUM

  All these procedures, run in $O(\log n)$ time, allow the heap data structure to be used as a priority queue.
- Each call to MAX-HEAPIFY costs $O(\log n)$ time, and there are $O(n)$ such calls. Thus, the running time is $O(n \log n)$
- The HEAPSORT procedure takes time $O(n \log n)$, since the call to BUILD-MAX-HEAP takes time $O(n)$ and each of the $(n-1)$ calls to MAX-HEAPIFY takes time $O(\log n)$.

Priority Queues

The most popular application of a heap is its use as an efficient priority queue.

A priority queue is a data structure for maintaining a set S of elements, each with an associated value called a key. A max-priority queue supports the following operations:

INSERT: INSERT (s, x) inserts the element x into the set S. This operation can be written as $S \leftarrow S\ U\ \{x\}$.

MAXIMUM: MAXIMUM (S) returns the element of S with the largest key

EXTRACT-MAX: EXTRACT-MAX(S) removes and returns the element of S with the largest key.

INCREASE-KEY: INCREASE-KEY(s, x, k) increases the value of element x's key to the new value k, which is assumed to be atleast as large as x's current key value.

One application of max–priority queue is to schedule jobs on a shared computer.

Exercises

Practice Problems 1

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Solve the recurrence relation $T(n) = 2T(n/2) + k.n$ where k is constant then $T(n)$ is

(A) $O(\log n)$ (B) $O(n \log n)$
(C) $O(n)$ (D) $O(n^2)$

2. What is the time complexity of the given code?

```
Void f(int n)
{
if (n > 0)
f (n/2);
}
```

(A) $\theta(\log n)$ (B) $\theta(n \log n)$
(C) $\theta(n^2)$ (D) $\theta(n)$

3. The running time of an algorithm is represented by the following recurrence relation;

$$T(n) = \begin{cases} n & n \le 3 \\ T\left[\dfrac{n}{3}\right] + cn & \text{otherwise} \end{cases}$$

What is the time complexity of the algorithm?

(A) $\theta(n)$ (B) $\theta(n \log n)$
(C) $\theta(n^2)$ (D) $\theta(n^2 \log n)$

Common data for questions 4 and 5:

4. The following pseudo code does which sorting?

$x$sort $[A, n]$

for $j \leftarrow 2$ to n

do key $\leftarrow A\ [\ i\ ]$

$i \leftarrow j - 1$

While $i > 0$ and $A\ [\ i\ ] >$ key

do $A\ [i + i] \leftarrow A\ [\ i\ ]$

$i \leftarrow i - 1$

$A\ [i + 1] \leftarrow$ key

(A) Selection sort (B) Insertion sort
(C) Quick sort (D) Merge sort

5. What is the order of elements after 2 iterations of the above-mentioned sort on given elements?

8	2	4	9	3	6

(A)

2	4	9	8	3	6

(B)

2	4	8	9	3	6

(C)

2	4	6	3	8	9

(D)

2	4	6	3	8	9

Common data for questions 6 and 7:

6. The following pseudo code does which sort?

1. If $n = 1$ done
2. Recursively sort
   A [1…[n/2]]and
   A [[n/2] + 1 … n]
3. Combine 2 ordered lists

(A) Insertion sort (B) Selection sort
(C) Merge sort (D) Quick sort

7. What is the complexity of the above pseudo code?
(A) $\theta(\log n)$ (B) $\theta(n^2)$
(C) $\theta(n \log n)$ (D) $\theta(2^n)$

8. Apply Quick sort on a given sequence 6 10 13 5 8 3 2 11. What is the sequence after first phase, pivot is first element?
(A) 5 3 2 6 10 8 13 11
(B) 5 2 3 6 8 13 10 11
(C) 6 5 13 10 8 3 2 11
(D) 6 5 3 2 8 13 10 11

9. Selection sort is applied on a given sequence:
89, 45, 68, 90, 29, 34, 17. What is the sequence after 2 iterations?
(A) 17, 29, 68, 90, 45, 34, 89
(B) 17, 45, 68, 90, 29, 34, 89
(C) 17, 68, 45, 90, 34, 29, 89
(D) 17, 29, 68, 90, 34, 45, 89

10. Suppose there are log n sorted lists of $\left\lfloor \frac{n}{\log n} \right\rfloor$ elements each. The time complexity of producing sorted lists of all these elements is: (hint: use a heap data structure)
(A) $\theta(n \log \log n)$ (B) $\theta(n \log n)$
(C) $\Omega(n \log n)$ (D) $\Omega(n^{3/2})$

11. If Divide and conquer methodology is applied on powering a Number X^n. Which one the following is correct?
(A) $X^n = X^{n/2} \cdot X^{n/2}$
(B) $X^n = X^{\frac{n-1}{2}} \cdot X^{\frac{n-1}{2}} \cdot X$
(C) $X^n = X^{\frac{n+1}{2}} \cdot X^{\frac{n}{2}}$
(D) Both (A) and (B)

12. The usual $\theta(n^2)$ implementation of insertion sort to sort an array uses linear search to identify the position, where an element is to be inserted into the already sorted part of the array. If binary search is used instead of linear search to identify the position, the worst case running time would be.
(A) $\theta(n \log n)$
(B) $\theta(n^2)$
(C) $\theta(n(\log n)^2)$
(D) $\theta(n)$

13. Consider the process of inserting an element into a max heap where the max heap is represented by an array, suppose we perform a binary search on the path from the new leaf to the root to find the position for the newly inserted element, the number of comparisons performed is:
(A) $\theta(\log n)$ (B) $\theta(\log \log n)$
(C) $\theta(n)$ (D) $\theta(n \log n)$

14. Consider the following algorithm for searching a given number 'X' in an unsorted array $A[1 \cdots n]$ having 'n' distinct values:
(1) Choose an 'i' uniformly at random from $1 \cdots n$
(2) If $A[i] = x$
Then stop
else
goto(1);
Assuming that X is present in A, what is the expected number of comparisons made by the algorithm before it terminates.
(A) n (B) $n - 1$
(C) $2n$ (D) $n/2$

15. The recurrence equation for the number of additions $A(n)$ made by the divide and conquer algorithm on input size $n = 2^K$ is
(A) $A(n) = 2A(n/2) + 1$ (B) $A(n) = 2A(n/2) + n^2$
(C) $A(n) = 2A(n/4) + n^2$ (D) $A(n) = 2A(n/8) + n^2$

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1.

Input Array	Linear Search $W(n)$	Binary search $W(n)$
128 elements	128	8
1024 elements	1024	x

Find x value?
(A) 10 (B) 11
(C) 12 (D) 13

2. Choose the correct one
(i) $\log n$ (ii) n
(iii) $n \log n$ (iv) n^2
(a) A result of cutting a problem size by a constant factor on each iteration of the algorithm.
(b) Algorithm that scans a list of size 'n'.
(c) Many divide and conquer algorithms fall in this category.
(d) Typically characterizes efficiency of algorithm with two embedded loops.
(A) i – b, ii – c, iii – a, iv – d
(B) i – a, ii – b, iii – c, iv – d
(C) i – c, ii – d, iii – a, iv – b
(D) i – d, ii – a, iii – b, iv – c

3. Insertion sort analysis in worst case
(A) $\theta(n)$
(B) $\theta(n^2)$
(C) $\theta(n \log n)$
(D) $\theta(2^n)$

4. From the recurrence relation. Of merge sort $T(n) = 2T(n/2) + \theta(n)$.
Which option is correct?
I. $n/2$ II. 2T III. $\theta(n)$
(a) Extra work (divide and conquer)
(b) Sub-problem size
(c) Number of sub-problems
(A) III – b, II – a, I – c (B) I – b, II – c, III – a
(C) I – a, II – c, III – b (D) I – c, II – a, III – b

5. What is the number of swaps required to sort 'n' elements using selection sort, in the worst case?
(A) $\theta(n)$ (B) $\theta(n^2)$
(C) $\theta(n \log n)$ (D) $\theta(n^2 \log n)$

6. In a binary max heap containing 'n' numbers, the smallest element can be found in time
(A) $O(n)$ (B) $O(\log n)$
(C) $O(\log \log n)$ (D) $O(1)$

7. What is the worst case complexity of sorting 'n' numbers using quick sort?
(A) $\theta(n)$ (B) $\theta(n \log n)$
(C) $\theta(n^2)$ (D) $\theta(n\,!)$

8. The best case analysis of quick sort is, if partition splits the array of size n into
(A) $n/2 : n/m$ (B) $n/2 : n/2$
(C) $n/3 : n/2$ (D) $n/4 : n/2$

9. What is the time complexity of powering a number, by using divide and conquer methodology?
(A) $\theta(n^2)$ (B) $\theta(n)$
(C) $\theta(\log n)$ (D) $\theta(n \log n)$

10. Which one of the following in-place sorting algorithm needs the minimum number of swaps?
(A) Quick sort (B) Insertion sort
(C) Selection sort (D) Heap sort

11. As the size of the array grows what is the time complexity of finding an element using binary search (array of elements are ordered)?
(A) $\theta(n \log n)$ (B) $\theta(\log n)$
(C) $\theta(n^2)$ (D) $\theta(n)$

12. The time complexity of heap sort algorithm is
(A) $n \log n$ (B) $\log n$
(C) n^2 (D) None of these.

13. As part of maintenance work, you are entrusted with the work of rearranging the library books in a shelf in a proper order, at the end of each day. The ideal choices will be_____.
(A) Heap sort (B) Quick sort
(C) Selection sort (D) Insertion sort

14. The value for which you are searching is called
(A) Binary value
(B) Search argument
(C) Key
(D) Serial value

15. To sort many large objects and structures it would be most efficient to _____.
(A) Place them in an array and sort the array
(B) Place the pointers on them in an array and sort the array
(C) Place them in a linked list and sort the linked list
(D) None of the above

Previous Years' Questions

1. What is the number of swaps required to sort n elements using selection sort, in the worst case? **[2009]**
(A) $\theta(n)$
(B) $\theta(n \log n)$
(C) $\theta(n^2)$
(D) $\theta(n^2 \log n)$

2. Which one of the following is the tightest upper bound that represents the number of swaps required to sort n numbers using selection sort? **[2013]**
(A) $O(\log n)$ (B) $O(n)$
(C) $O(n \log n)$ (D) $O(n^2)$

3. Let P be a quick sort program to sort numbers in ascending order using the first element as the pivot. Let t_1 and t_2 be the number of comparisons made by P for the inputs [1 2 3 4 5] and [4 1 5 3 2] respectively. Which one of the following holds? **[2014]**
(A) $t_1 = 5$ (B) $t_1 < t_2$
(C) $t_1 > t_2$ (D) $t_1 = t_2$

4. The minimum number of comparisons required to find the minimum and the maximum of 100 numbers is ———. **[2014]**

5. Suppose P, Q, R, S, T are sorted sequences having lengths 20, 24, 30, 35, 50 respectively. They are to be merged into a single sequence by merging together two sequences at a time. The number of comparisons that will be needed in the worst case by the optimal algorithm for doing this is ———. **[2014]**

6. You have an array of n elements. Suppose you implement quick sort by always choosing the central element of the array as the pivot. Then the tightest upper bound for the worst case performance is **[2014]**
(A) $O(n^2)$ (B) $O(n \log n)$
(C) $\theta(n \log n)$ (D) $O(n^3)$

7. What are the worst-case complexities of insertion and deletion of a key in a binary search tree? **[2015]**

(A) $\theta(\log n)$ for both insertion and deletion
(B) $\theta(n)$ for both insertion and deletion
(C) $\theta(n)$ for insertion and $\theta(\log n)$ for deletion
(D) $\theta(\log n)$ for insertion and $\theta(n)$ for deletion

8. The worst case running times of *Insertion sort, Merge sort* and *Quick sort*, respectively, are: **[2016]**
(A) $\Theta(n \log n)$, $\Theta(n \log n)$,and $\Theta(n^2)$
(B) $\Theta(n^2)$, $\Theta(n^2)$,and $\Theta(n \log n)$
(C) $\Theta(n^2)$, $\Theta(n \log n)$,and $\Theta(n \log n)$
(D) $\Theta(n^2)$, $\Theta(n \log n)$,and $\Theta(n^2)$

9. An operator delete(i) for a binary heap data structure is to be designed to delete the item in the i-th node. Assume that the heap is implemented in an array and i refers to the i-th index of the array. If the heap tree has depth d (number of edges on the path from the root to the farthest leaf), then what is the time complexity to re-fix the heap efficiently after the removal of the element? **[2016]**
(A) $O(1)$ (B) $O(d)$ but not $O(1)$
(C) $O(2^d)$ but not $O(d)$ (D) $O(d2^d)$ but not $O(2^d)$

10. Assume that the algorithms considered here sort the input sequences in ascending order. If the input is already in ascending order, which of the following are **TRUE**? **[2016]**
I. Quicksort runs in $\Theta(n^2)$ time
II. Bubblesort runs in $\Theta(n^2)$ time
III. Mergesort runs in $\Theta(n)$ time
IV. Insertion sort runs in Θ (n) time

(A) I and II only (B) I and III only
(C) II and IV only (D) I and IV only

11. A complete binary min - heap is made by including each integer in [1,1023] exactly once. The depth of a node in the heap is the length of the path from the root of the heap to that node. Thus, the root is depth 0. The maximum depth at which integer 9 can appear is _____ . **[2016]**

Divide-and-Conquer

Divide-and-conquer is a top down technique for designing algorithms that consists of dividing the problem into smaller sub problems hoping that the solutions of the sub problems are easier to find and then composing the partial solutions into the solution of the original problem.

Divide-and-conquer paradigm consists of following major phases:

- Breaking the problem into several sub-problems that are similar to the original problem but smaller in size.
- Solve the sub-problem recursively (successively and independently)
- Finally, combine these solutions to sub-problems to create a solution to the original problem.

Divide-and-Conquer Examples

- Sorting: Merge sort and quick sort
- Binary tree traversals
- Binary Search
- Multiplication of large integers
- Matrix multiplication: Strassen's algorithm
- Closest-pair and Convex-hull algorithm

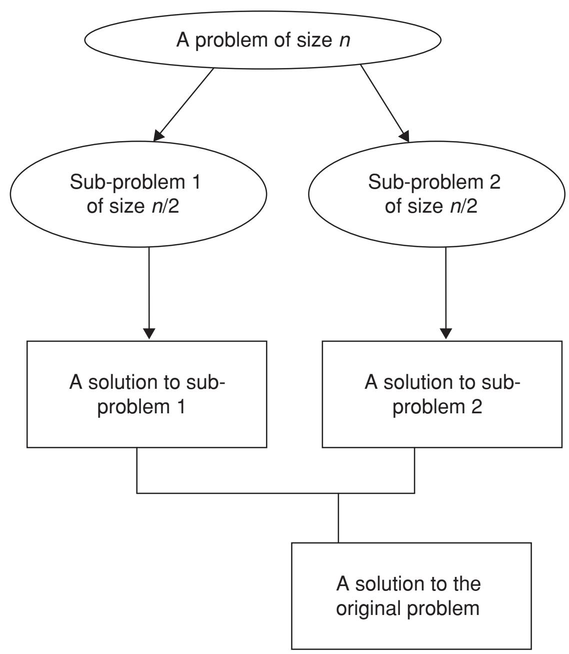

Figure 1 Divide-and-conquer technique.

Merge Sort

Merge sort is a sorting algorithm for rearranging lists (or any other data structure that can only be accessed sequentially, e.g., file streams) into a specified order.

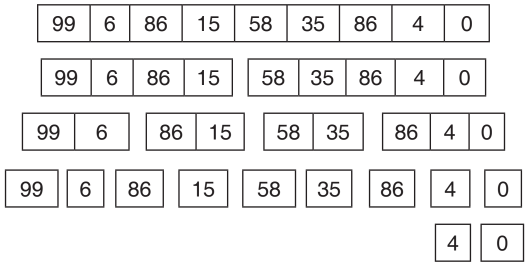
Merge sort works as follows:

1. Divide the unsorted list into two sub lists of about half the size.
2. Sort each of the two sub lists.
3. Merge the two sorted sub lists back into one sorted list
4. The key of merge sort is merging two sorted lists into one, such that if we have 2 lists
   $X(x_1 \le x_2 \le x_3 \cdots \le x_m)$ and
   $Y(y_1 \le y_2 \le y_3 \cdots \le y_n)$ the resulting list is $z\,(z_1 \le z_2 \le \cdots \le z_{m+n})$

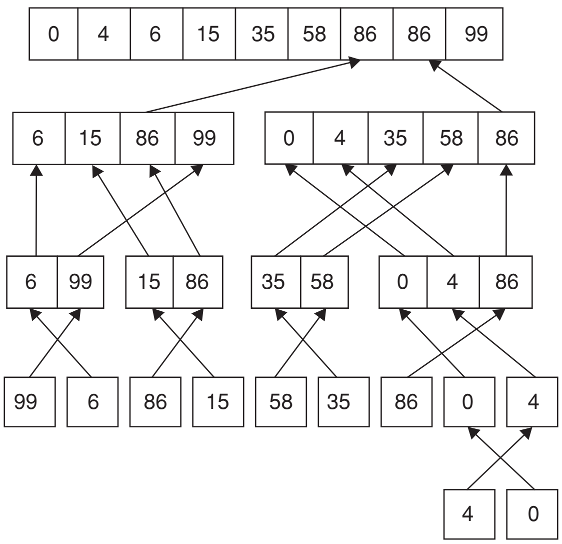
Example 1: $L_1 = \{3, 8, 9\}$, $L_2 = \{1, 5, 7\}$

Merge $(L_1, L_2) = \{1, 3, 5, 7, 8, 9\}$

Example 2:



Merge:



Implementing Merge Sort

Merging is done with a temporary array of the same size as the input array.

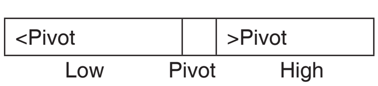
Pro: Faster than in-place since the temp array holds the resulting array until both left and right sides are merged into the temp array then the temp array is appended over the input array.

Con: The memory required is doubled. The double memory merge sort runs $O(N \log N)$ for all cases, because of its Divide-and-conquer approach.

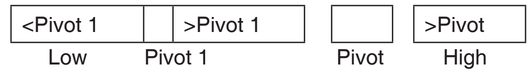
$$T(N) = 2T(N/2) + N$$
$$= O(N \log N)$$

Quick Sort

Quick sort is an example of Divide-and-conquer strategy. In Quick sort we divide the array of items to be sorted into two partitions and then call the quick sort procedure recursively to sort the two partitions, i.e., we divide the problem into two smaller ones and conquer by solving the smaller ones. The conquer part of the quick sort routine looks like this



Make bold



Divide: Partition the array A $[p - r]$ into 2 sub arrays A $[p - q - 1]$ and A $[q + 1 - r]$ such that each element of A $[p - q - 1]$ is less than or equal to A$[q]$, which is, in turn, less than or equal to each element of A $[q + 1 - r]$

Conquer: Sort the 2 sub arrays A $[p - q - 1]$ and A $[q + 1 - r]$ by recursive calls to quick sort.

Combine: Since the sub arrays are sorted inplace, no work is needed to combine them.

Sort left partition in the same way. For this strategy to be effective, the partition phase must ensure that the pivot, is greater than all the items in one part (the lower part) and less than all those in the other (upper) part. To do this, we choose a pivot element and arrange that all the items in the lower part are less than the pivot and all those in the upper part are greater than it. In the general case, the choice of pivot element is first element.

(Here $\lfloor$number of elements/2$\rfloor$ is pivot)

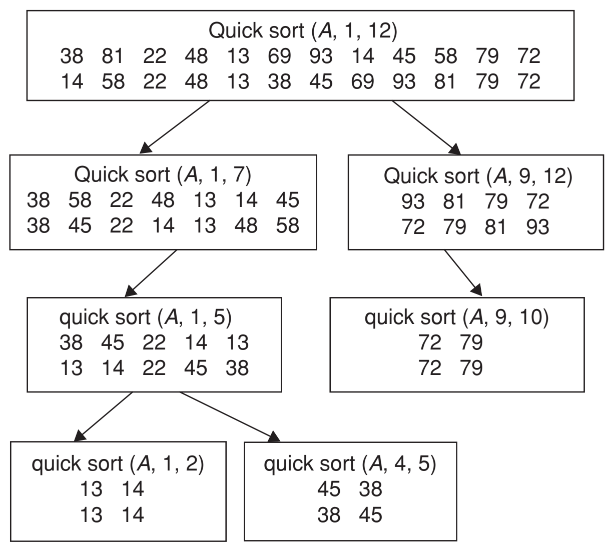


Figure 2 Tree of recursive calls to quick sort.

- Quick sort is a sorting algorithm with worst case running time $O(n^2)$ on an input array of n numbers. Inspite of this slow worst case running time, quick sort is often the best practical choice for sorting because it is efficient on the average: its expected running time is $O(n \log n)$ and the constants hidden in the O-notation are quite small
- Quick sort algorithm is fastest when the median of the array is chosen as the pivot element. This is because the resulting partitions are of very similar size. Each partition splits itself in two and thus the base case is reached very quickly.

Example: Underlined element is pivot.

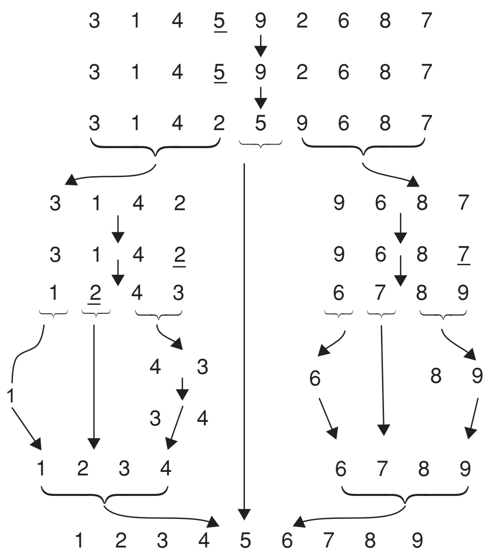

Figure 3 The ideal quick sort on a random array

Performance of Quick Sort

- Running time of quick sort depends on whether the partitioning is balanced or unbalanced, it depends on which elements are used for partitioning. If the partitioning is balanced, the algorithm runs asymptotically as fast as merge sort. If the partitioning is unbalanced, it runs as slowly as insertion sort.
- The worst case of quick sort occurs when the partitioning routine produces one sub-problem with $n - 1$ elements and one with '1' element. If this unbalanced partitioning arises in each recursive call, the partitioning costs $\theta(n)$ time.

Recurrence Relation

$$T(n) = T(n-1) + T(1) + \theta(n)$$
$$(\therefore\ T(0) = \theta(1))$$
$$= T(n-1) + \theta(n)$$

If we sum the costs incurred at each level of the recursion we get an arithmetic series, which evaluates to $\theta(n^2)$.

- Best case partitioning–PARTITION produces 2 sub problems, each of size no more than $n/2$, since one is of size $\lfloor n/2 \rfloor$ and one of size $\lceil n/2 \rceil - 1$

  The recurrence for the running time is then

$$T(n) \le 2T(n/2) + \theta(n)$$

The above Recurrence relation has the solution $T(n) = O(n \log n)$ by case 2 of the master theorem.

- The average–case time of quick sort is much closer to the best than to the worst case

For example, that the partitioning algorithm always produces a 8-to-2 proportional split, which at first seems unbalanced. The Recurrence relation will be

$$T(n) \le T(8n/10) + T(2n/10) + cn$$

The recursion tree for this recurrence has cost 'cn' at every level, until a boundary condition is reached at depth $\log_{10} n = \theta(\log n)$. The recursion terminates at depth $\log_{10/8} n = \theta(\log n)$. The total cost of quick sort is $O(n \log n)$

Searching

Two searching techniques are:

- Linear search
- Binary search

Linear Search

Linear search (or) sequential search is a method for finding a particular value in list that consists of checking every one of its elements, one at a time and in sequence, until the desired one is found. Linear search is a special case of brute force search. Its worst case cost is proportional to the number of elements in the list.

Implementation

```
boolean linear search (int [ ] arr, int target)
{
int i = 0;
while (i < arr. length) {
if (arr [i] = = target){
return true;
}
+ + i;
}
return false;
}
```

Example:

Consider the array

10	7	1	3	–4	2	20

Search for 3

10	7	1	3	–4	2	20
3?						

Move to next element

10	7	1	3	–4	2	20
	3?					

Move to next element

10	7	1	3	–4	2	20
		3?				

Move to next element

10	7	1	3	–4	2	20
			3?			

Element found; stop the search.

Binary Search

A binary search algorithm is a technique for finding a particular value in a linear array, by ruling out half of the data at each

step; a binary search finds the median, makes comparison, to determine whether the desired value comes before or after it, and then searches the remaining half in the same manner. A binary search is an example of Divide-and-conquer algorithm.

Implementation

function binary search (a, value, left, right)

```
{
if right < left
        return not found
      mid: = floor ((right -left)/2) + left
      if a [mid] = value
      return mid
      if value < a[mid]
```

return binary search (a, value, left, mid –1) else return binary search (a, value, mid + 1, right)

```
}
```

Example: Value being searched 123

2 6 7 34 76 123 234 567 677 986

First (1) mid(5) Last(10)

2 6 7 34 76 123 234 567 677 986

First (6) mid(8) Last(10)

2 6 7 34 76 123 234 567 677 986

First (6) Last(7)
Mid (6)

2 6 7 34 76 123 234 567 677 986

First, mid, last (6)

Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. How many comparisons are required to search an item 89 in a given list, using Binary search?

4	8	19	25	34	39	45	48	66	75	89	95
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

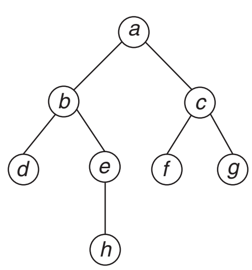
(A) 3 (B) 4
(C) 5 (D) 6

2. Construct a Binary search tree with the given list of elements:

300, 210, 400, 150, 220, 370, 450, 100, 175, 215, 250

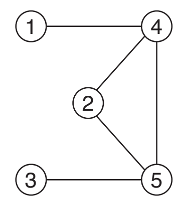
Which of the following is a parent node of element 250?
(A) 220
(B) 150
(C) 370
(D) 215

3. What is the breadth first search order of the given tree?



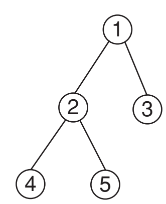
(A) acbhdefg (B) abcdefgh
(C) adbcefgh (D) aebcdfgh

4. What is the depth first search order of the given graph?



(A) 14325
(B) 12435
(C) 14253
(D) 12354

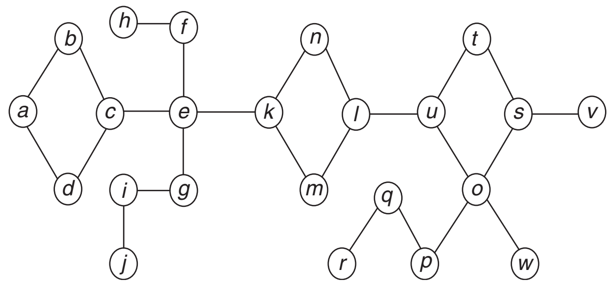
5. When pre-order traversal is applied on a given tree, what is the order of elements?



(A) 1 – 2 – 4 – 5 – 3
(B) 1 – 4 – 2 – 5 – 3
(C) 1 – 2 – 4 – 3 – 5
(D) 1 – 2 – 3 – 4 – 5

6. What is the order of post-order traversal and in-order traversals of graph given in the above question?
(A) 4 – 2 – 5 – 1 – 3 and 4 – 5 – 2 – 3 – 1
(B) 4 – 5 – 2 – 3 – 1 and 4 – 2 – 5 – 1 – 3
(C) 4 – 5 – 2 – 1 – 3 and 4 – 2 – 5 – 1 – 3
(D) 4 – 5 – 2 – 3 – 1 and 4 – 2 – 5 – 3 – 1

7. Find the number of bridges in the given graph

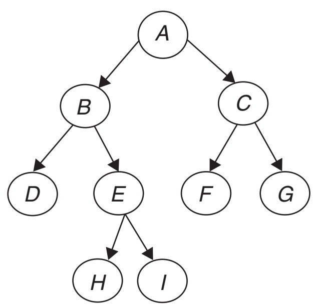


(A) 12 (B) 13
(C) 11 (D) 10

8. Match the following:

I.	In-order	1.	*ABCDEFGHI*
II.	Pre-order	2.	*DBHEIAFCG*
III.	Post-order	3.	*ABDEHICFG*
IV.	Level-order	4.	*DHIEBFGCA*

For the tree



(A) I – 2, II – 3, III – 4, IV – 1
(B) I – 3, II – 1, III – 4, IV – 2
(C) I – 1, II – 2, III – 3, IV – 4
(D) I – 4, II – 3, III – 2, IV – 1

9. A complete *n*-array tree in which each node has '*n*' children (or) no children.

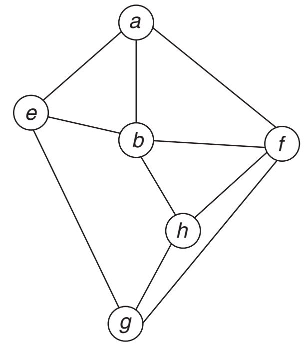
Let '*I*' be the number of internal nodes and '*L*' be the number of leaves in a complete *n*-ary tree.

If $L = 51$ and $I = 10$ what is the value of '*n*'?
(A) 4 (B) 5
(C) 6 (D) Both (A) and (B)

10. A complete *n*-ary tree is one in which every node has 0 (or) *n* children. If '*X*' is the number of internal nodes of a complete *n*-ary tree, the number of leaves in it is given by
(A) $X(n - 1) + 1$ (B) $Xn - 1$
(C) $Xn + 1$ (D) $X(n + 1) + 1$

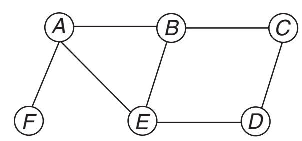
11. The numbers 7, 5, 1, 8, 3, 6, 0, 9, 4, 2 are inserted in the given order into an initially empty binary search tree. The binary search tree uses the usual ordering on natural numbers. What is the in-order traversal sequence of the resultant tree?
(A) 7 5 1 0 3 2 4 6 8 9
(B) 0 2 4 3 1 6 5 9 8 7
(C) 0 1 2 3 4 5 6 7 8 9
(D) 9 8 6 4 2 3 0 1 5 7

12. Consider the following graph:



Among the following sequences
I. *a b e g h f* II. *a b f e h g*
III. *a b f h g e* IV. *a f g h b e*
Which are depth first traversals of the above graph?
(A) I, II and IV only (B) I and IV only
(C) I, III only (D) I, III and IV only

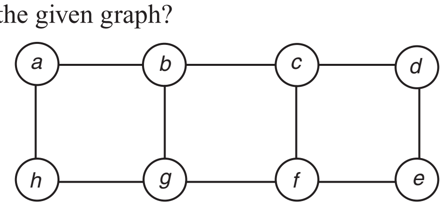
13. The breadth first search algorithm has been implemented using the queue data structure. One possible order of visiting the nodes is



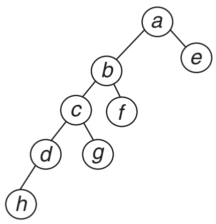
(A) *A B C D E F* (B) *B E A D C F*
(C) *E A B D F C* (D) Both (A) and (B)

14. An undirected graph *G* has '*n*' nodes. Its adjacency matrix is given by an $n \times n$ square matrix.
(i) Diagonal elements are 0's
(ii) Non-diagonal elements are 1's
Which of the following is true?
(A) Graph *G* has no minimum spanning tree
(B) Graph *G* has a unique minimum spanning tree of cost $(n - 1)$
(C) Graph *G* has multiple distinct minimum spanning trees, each of cost $(n - 1)$
(D) Graph *G* has multiple spanning trees of different cost.

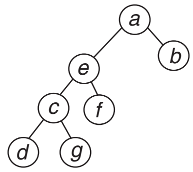
15. Which of the following is the breadth first search tree for the given graph?



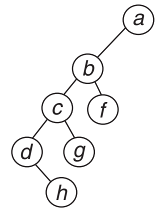
(A)



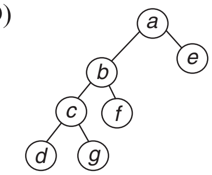
(B)



(C)



(D)



Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Which of the following algorithm design technique is used in finding all pairs of shortest distances in a graph?
(A) Divide-and-conquer
(B) Greedy method
(C) Back tracking
(D) Dynamic programming

2. Let LASTPOST, LASTIN and LASTPRE denote the last vertex visited in a post-order, in-order and pre-order traversals respectively of a complete binary tree. Which of the following is always true?
(A) LASTIN = LASTPOST
(B) LASTIN = LASTPRE
(C) LASTPRE = LASTPOST
(D) LASTIN = LASTPOST = LASTPRE

3. Match the following:

X : Depth first search

Y : Breadth first search

Z : Sorting

a : Heap

b : Queue

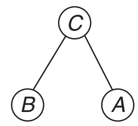
c : Stack

(A) X – a, Y – b, Z – c
(B) X – c, Y – a, Z – b
(C) X – c, Y – b, Z – a
(D) X – a, Y – c, Z – b

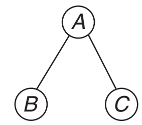
4. Let G be an undirected graph, consider a depth first traversal of G, and let T be the resulting DFS Tree. Let 'U' be a vertex in 'G' and let 'V' be the first new (unvisited) vertex visited after visiting 'U' in the traversal. Which of the following is true?
(A) $\{U, V\}$ must be an edge in G and 'U' is a descendant of V in T.
(B) $\{U, V\}$ must be an edge in 'G' and V is a descendant of 'U' in T.
(C) If $\{U, V\}$ is not an edge in 'G' then 'U' is a leaf in T.
(D) if $\{U, V\}$ is not an edge in G then U and V must have the same parent in T.

5. Identify the binary tree with 3 nodes labeled A, B and C on which preorder traversal gives the sequence C, B, A.

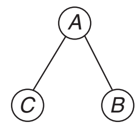
(A)



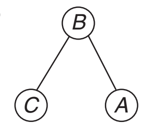
(B)



(C)



(D)

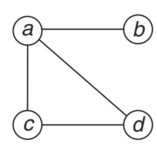


6. Consider an undirected unweighted graph G. Let a breadth first traversal of G be done starting from a node r. Let $d(r, u)$ and $d(r, v)$ be the lengths of the shortest paths from r to u and v respectively in 'G'. If u is visited before v during the breadth first travel, which of the following is correct?
(A) $d(r, u) < d(r, v)$
(B) $d(r, u) > d(r, v)$
(C) $d(r, u) \leq d(r, v)$
(D) None of these

7. In a complete 5-ary tree, every internal node has exactly 5 children. The number of leaves in such a tree with '3' internal nodes are:
(A) 15
(B) 20
(C) 13
(D) Can't predicted

8. Which of the following algorithm is single pass that is they do not traverse back up the tree for search, create, insert etc.
(A) Depth first search
(B) Pre-order traversal
(C) B-tree traversal
(D) Post-order traversal

9. Which of the following is the adjacency matrix of the given graph?



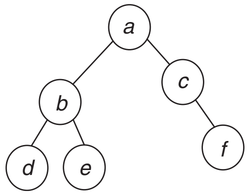
(A) $\begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{bmatrix}$

(B) $\begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$

(C) $\begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{bmatrix}$

(D) $\begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$

10. Which one of the following is the post-order traversal of the given tree?

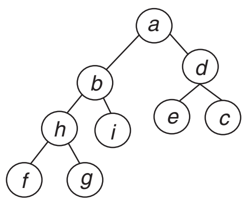


(A) *d e a f c b a* (B) *d e b f c a*
(C) *e b d f c a* (D) *a b c d e f*

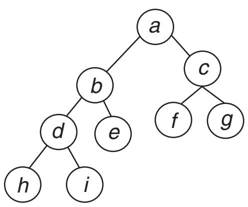
Common data for questions 11 and 12:

11. The pre-order traversal of a tree is *a b d h i e c f g*. Which of the following is the correct tree?

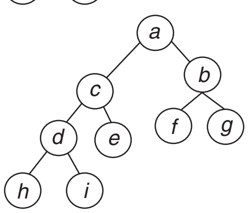
(A)



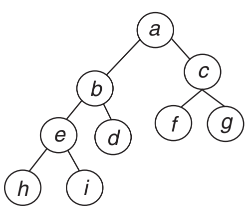
(B)



(C)



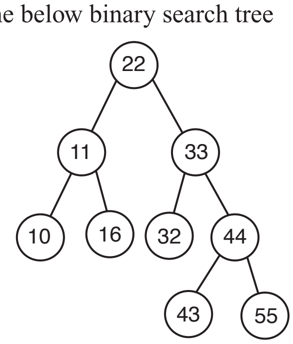
(D)



12. Which of the following is in-order traversal of the above tree?

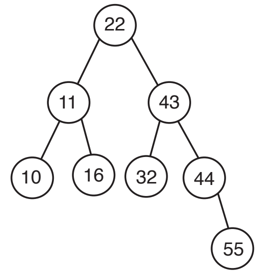
(A) *a b h d e i f g c* (B) *a b d h e i f g c*
(C) *h d i b e a f c g* (D) *i d h b e a f c g*

13. Consider the below binary search tree

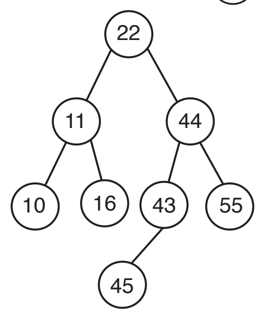


Which of the following is the resultant binary search tree after deletion of 33?

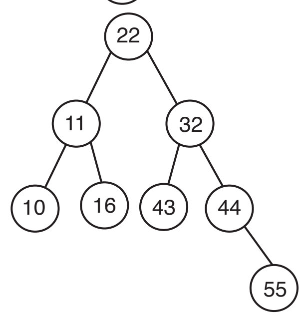
(A)



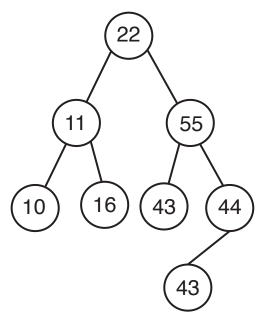
(B)



(C)



(D)



14. Match the following:

I.	Articulation Point	1.	An edge whose removal disconnects graph
II.	Bridge	2.	A vertex whose removal disconnects graph
III.	Bi connected component	3.	Maximal set of edges such that any two edges in the set lie on a common simple cycle

(A) I – 1, II – 2, III – 3 (B) I – 2, II – 1, III – 3
(C) I – 2, II – 3, III – 1 (D) I – 1, II – 2, III – 3

15. If x is the root of an n-node subtree, then the inorder-tree-walk takes

(A) $\theta(n)$ (B) $\theta(n^2)$
(C) $\theta(n^3)$ (D) $\theta(n \log n)$

Previous Years' Questions

1. Which one of the following is the tightest upper bound that represents the time complexity of inserting an object into a binary search tree of n nodes? **[2013]**

   (A) $O(1)$ (B) $O(\log n)$
   (C) $O(n)$ (D) $O(n \log n)$

2. Consider a rooted n node binary tree represented using pointers. The best upper bound on the time required to determine the number of sub trees having exactly 4 nodes is $O(n^a \log^b n)$. The value of $a + 10b$ is ________ **[2014]**

3. Which one of the following is the recurrence equation for the worst case time complexity of the Quicksort algorithm for sorting $n(\geq 2)$ numbers? In the recurrence equations given in the options below, c is a constant. **[2015]**

   (A) $T(n) = 2T(n/2) + cn$
   (B) $T(n) = T(n - 1) + T(1) + cn$
   (C) $T(n) = 2T(n - 1) + cn$
   (D) $T(n) = T(n/2) + cn$

4. Suppose you are provided with the following function declaration in the C programming language.

   int partition (int *a*[ ], int *n*);

   The function treats the first element of *a* [ ] as a pivot, and rearranges the array so that all elements less than or equal to the pivot is in the left part of the array, and all elements greater than the pivot is in the right part in addition, it moves the pivot so that the pivot is the last element of the left part. The return value is the number of elements in the left part.

   The following partially given function in the C programming language is used to find the *k*th smallest element in an array *a* [ ] of size *n* using the partition function. We assume *k* ″ *n*.

   int *k*th_smallest (int *a* [ ], int *n*, int *k*) **[2015]**

```
{
    int left_end = partition(a, n);
    if (left_end+1 == k) {
      return a [left_end];
    )
    if (left_end+1 > k) {
      return kth_smallest (___________);
    } else {
      return kth_smallest (___________);
    }
}
```

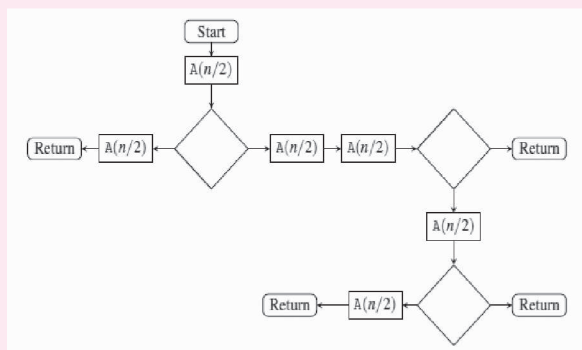
   The missing argument lists are respectively
   (A) (*a*, left_end, *k*) and (*a*+left_end+1, *n*-left_end-1, *k*-left_end-1)
   (B) (*a*, left_end, *k*) and (*a*, *n*-left_end-1, *k*-left_end-1)
   (C) (*a*+left_end+1, *n*-left_end-1, *k*-left_end-1) and (*a*, left_end, *k*)
   (D) (*a*, *n*-left_end-1, *k*-left_end-1) and (*a*, left_end, *k*)

5. Assume that a mergesort algorithm in the worst case takes 30 seconds for an input of size 64. Which of the following most closely approximates the maximum input size of a problem that can be solved in 6 minutes? **[2015]**

   (A) 256 (B) 512
   (C) 1024 (D) 2048

6. The given diagram shows the flowchart for a recursive function A(n). Assume that all statements, except for the recursive calls, have O (1) time complexity. If the worst case time complexity of this function is O (n^{α}), then the least possible value (accurate up to two decimal positions) of α is ____. **[2016]**

   Flowchart for Recursive Function A(n)



7. Let A be an array of 31 numbers consisting of a sequence of 0's followed by a sequence of 1's. The problem is to find the smallest index i such that $A[i]$ is 1 by probing the minimum number of locations in A. The *worst case* number of probes performed by an *optimal* algorithm is _______. **[2017]**

8. Match the algorithms with their time complexities:

Algorithm	Time complexity
(P) Towers of Hanoi with n disks	(i) $\Theta(n^2)$
(Q) Binary search given n sorted numbers	(ii) $\Theta(n \log n)$
(R) Heap sort given n numbers at the worst case	(iii) $\Theta(2^n)$
(S) Addition of two $n \times n$ matrices	(iv) $\Theta(\log n)$

[2017]

   (A) P → (iii), Q → (iv), R → (i), S → (ii)
   (B) P → (iv), Q → (iii), R → (i), S → (ii)
   (C) P → (iii), Q → (iv), R → (ii), S → (i)
   (D) P → (iv), Q → (iii), R → (ii), S → (i)

Chapter 4

Greedy Approach

LEARNING OBJECTIVES

- Greedy approach
- Knapsack problem
- Fractional knapsack problem
- Spanning trees
- Prim's algorithm
- Kruskal's algorithm
- Tree and graph traversals
- Back tracking
- Graph traversal
- Breadth first traversal
- Depth first search
- Huffman codes
- Task-scheduling problem
- Sorting and order statistics
- Simultaneous minimum and maximum
- Graph algorithms

Greedy Approach

In a greedy method, we attempt to construct an optimal solution in stages.

- At each stage we make a decision that appears to be the best (under some criterion) at the time.
- A decision made at one stage is not changed in a later stage, so each decision should assure feasibility.
- Some problems that use greedy approach are:

1. Knapsack problem
2. Minimum spanning tree
3. Prims algorithm
4. Kruskals algorithm

Knapsack Problem

The knapsack problem is a problem in combinatorial optimization: given a set of items, each with a weight and a value, determine the number of each item to include in a collection so that the total weight is less than or equal to a given limit and the total value is as large as possible. We have n kinds of items, 1 through n. Each kind of item i has a value V_i and a weight W_i, usually assume that all values and weights are non-negative. The maximum weight that we can carry in the bag is W.

Solved Examples

Example 1: (Making change)

Problem:	Accept n dollars, to return a collection of coins with a total value of n dollars.
Configuration:	A collection of coins with a total value of n.
Objective function:	Minimize number of coins returned.
Greedy solution:	Always return the largest coin you can.

- Coins are valued \$.30, \$.020, \$0.05, \$0.01 use a greedy choice property and make \$.40 by using 3 coins.

Solution: \$0.30 + \$0.05 + \$0.05 = \$0.40

Fractional Knapsack Problem

Given: A set S of n items, with each item i having

- b_i – *a* positive benefit
- w_i – *a* positive weight

Goal: Choose items with maximum total benefit but with weight atmost W.

If we are allowed to take fractional amounts, then this is the fractional knapsack problem.

- In this case, let x_i denote the amount we take of item i.
- Objective: Maximize $\sum_{i \in S} b_i(x_i/w_i)$
- Constraint: $\sum_{i \in S} x^i \leq W$

Example 2:

Items

Weight	4 ml	8 ml	2 ml	6 ml	1 ml
Benefit	\$12	\$32	\$40	\$30	\$50
Value (\$ per ml)	3	4	20	5	50

"Knapsack"

10 ml

Solution: 1 ml of 5, 2 ml of 3, 6 ml of 4, 1 ml of 2

- Greedy choice: Keep taking item with highest value (benefit to weight ratio).
- Correctness: suppose there is a better solution, there is an item i with higher value than a chosen item *j*. (i.e., $v_j < v_i$). If we replace some j with i, we get a better solution.

Thus there is no better solution than the greedy one.
$N = 3$, $m = 20$
$(P_1, P_2, P_3) = (25, 24, 15)$
$(W_1, W_2, W_3) = (18, 15, 10)$

Example 3:

	$X_1\ X_2\ X_3$	$\Sigma\ W_iX_i$	$\Sigma\ P_i\ X_i$
1.	1/2 1/3 1/4	9 + 5 + 2.5 = 16.5	12.5 + 8 + 3.75 = 24.25
2.	1 2/15 0	18 + 2 + 0 = 20	25 + 3.2 + 0 = 28.2
3.	0 2/3 1	0 + 10 + 10 = 20	0 + 16 + 15 = 31
4.	0 1 1/2	0 + 15 + 5 = 20	0 + 24 + 7.5 = 31.5

(1), (2), (3), (4) are feasible ones but (4) is the optimum solution.

Spanning Trees

A spanning tree of a graph is just a sub graph that contains all the vertices and is a tree. A graph may have many spanning trees.

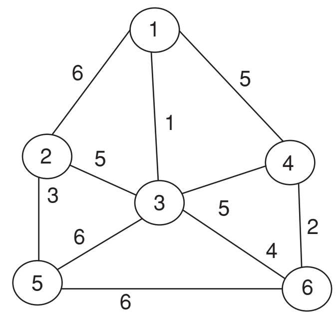
- A sub graph that spans (reaches out to) all vertices of a graph is called a spanning sub graph.
- A sub graph that is a tree and that spans all vertices of the original graph is called a spanning tree.
- Among all the spanning trees of a weighted and connected graph, the one (possibly more) with the least total weight is called a Minimum Spanning Tree (MST).

Prim's Algorithm

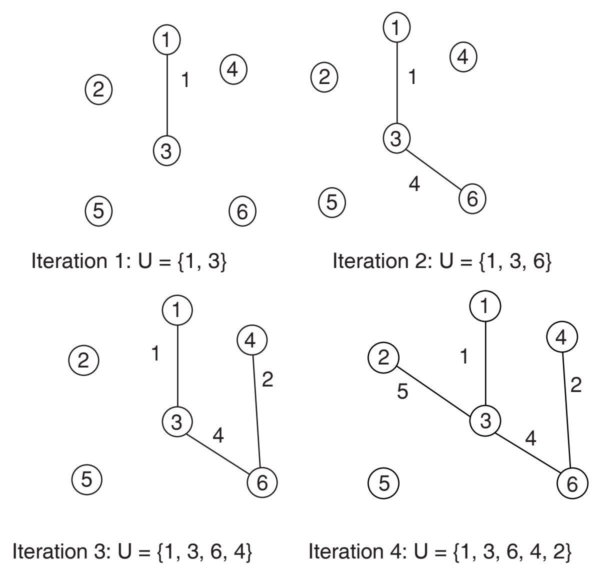
Prim's algorithm is a greedy algorithm that finds a minimum spanning tree for a connected weighted undirected graph. This means it finds a subset of the edges that forms a tree that includes every vertex, where the total weight of all the edges in the tree is minimized. The algorithm continuously increases the size, of a tree, one edge at a time starting with a tree consisting of a single vertex, until it spans all vertices.

- Using a simple binary heap data structure and an adjacency list representation, prim's algorithm can be shown to run in time $O(E \log V)$ where E is the number of edges and V is the number of vertices.

Example:



Start:



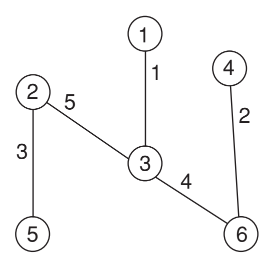


Figure 1 An example graph for illustrating prim's algorithm.

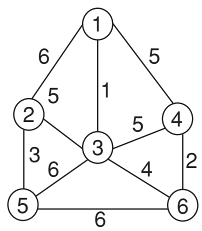
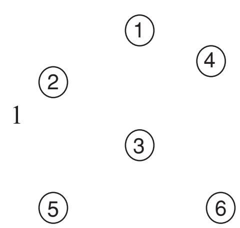
Kruskal's Algorithm

Like prim's algorithm, Kruskal's algorithm also constructs the minimum spanning tree of a graph by adding edges to the spanning tree one-by-one. At all points, during its execution the set of edges selected by prim's algorithm forms exactly one tree. On the other hand the set of edges selected by Kruskal's algorithm forms a forest of trees. Kruskals algorithm is conceptually simple. The edges are selected and added to the spanning tree in increasing order of their weights. An edge is added to the tree only if it does not create a cycle.

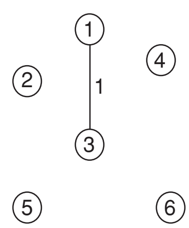
Example:



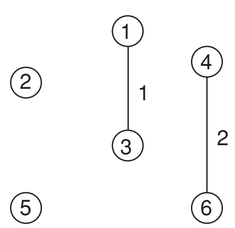
Start:



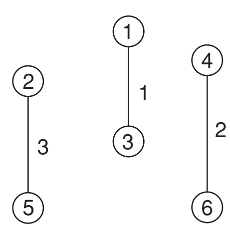
Initial configuration



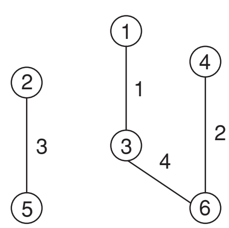
Setp 1: choose (1, 3)



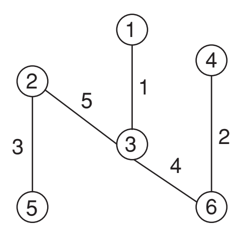
Setep 2: choose (4, 6)



Setep 3: choose (2, 5)



Setep 4: choose (3, 6)



Setep 6: choose (4, 3)

Tree and Graph Traversals

Back Tracking

Backtracking is a general algorithm technique that considers searching every possible combination in order to solve an optimization problem.

Backtracking is also known as depth first search (or) branch and bound. Backtracking is an important tool for solving constraint satisfaction problems, such as crosswords, verbal arithmetic, sudoku and many other puzzles. It is often the more convenient technique for parsing, for the knapsack problem and other combinational optimization problems.

- The advantage of backtracking algorithm is that they are complete, that is they are guaranteed to find every solution to every possible puzzle.

Graph Traversal

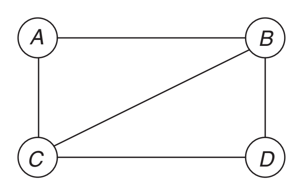
To traverse a graph is to process every node in the graph exactly once, because there are many paths leading from one node to another, the hardest part about traversing a graph is making sure that you do not process some node twice. There are general solutions to this difficulty.

1. When you first encounter a node, mark it as REACHED. When you visit a node, check if it is marked REACHED, if it is, just ignore it. This is the method our algorithms will use.
2. When you process a node, delete it from the graph. Deleting the node causes the deletion of all the arcs that lead to the node, so it will be impossible to reach it more than once.

General traversal strategy

1. Mark all nodes in the graph as NOT REACHED,
2. Pick a starting node, mark it as REACHED, and place it on the READY list.
3. Pick a node on the READY list. Process it remove it from READY. Find all its neighbors, those that are NOT REACHED should marked as REACHED and added to READY.
4. Repeat 3 until READY is empty.

Example:



Step I: $A = B = C = D =$ NOT REACHED
Step II: READY = {A} . A = REACHED
Step III: Process A. READY = {B, C}.
B = C = REACHED
Step IV: Process C. READY = {B, D}.
D = REACHED
Step V: Process B. READY = {D}
Step VI: Process D. READY = { }

The two most common traversal patterns are

- Breadth first traversal
- Depth first traversal

Breadth First Traversal

In breadth first traversal, READY is a QUEUE, not an arbitrary list. Nodes are processed in the order they are reached (FIFO), this has the effect of processing nodes according to their distance from the initial node. First, the initial node is processed. Then all its neighbors are processed. Then all of the neighbors etc.

- Since a graph has no root, we must specify the vertex at which to start the traversal.
- Breadth first tree traversal first visits all the nodes at depth zero (i.e., the root) then all the nodes at depth 1, and so on.

Procedure

First, the starting vertex is enqueued. Then, the following steps are repeated until the queue is empty.

1. Remove the vertex at the head of the queue and call it vertex.
2. Visit vertex
3. Follow each edge emanating from vertex to find the adjacent vertex and call it ‘t_o’. If ‘t_o’ has not already been put into the queue, enqueued it.

Notice, that a vertex can be put into the queue at most once. Therefore, the algorithm must some how keep track of the vertices that have been enqueued.

Procedure for BFS for undirected graph G(V, E)

To perform BFS over a graph, the data structures required are queue (Q) and the visited set (Visited), ‘V’ is the starting vertex.

Procedure for BFS(V)

Steps

1. Visit the vertex ‘V’
2. Enqueue the vertex V
3. while (Q is not Empty)
   (i) V = dequeue ();
   (ii) for all vertices ϑ adjacent to V
      (a) if not visited (ϑ)
         - Enqueue (ϑ)
         - Visit the vertex ‘ϑ’
         - end if.
         - end for
         - end while
         - Stop

Example:

A Unexplored vertex

A Visited vertex

Unexplored edge
Discovery edge
Cross edge

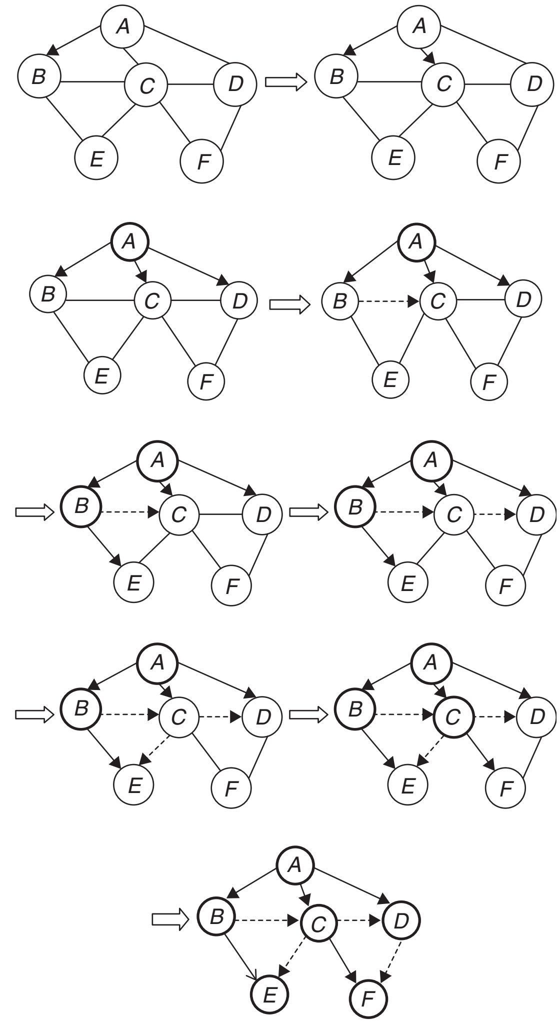


Figure 2 Breadth–first search

Depth First Search

A depth first traversal of a tree always starts at the root of the tree. Since a graph has no root, when we do a depth first traversal, we must specify the vertex at which to begin. A depth first traversal of a tree visits a node and then recursively visits the sub trees of that node similarly, depth first traversal of a graph visits a vertex and then recursively visits all the vertices adjacent to that node. A graph may contain cycles, but the traversal must visit every vertex at most once.

The solution to the problem is to keep track of the nodes that have been visited.

Procedure for DFS for undirected graph G(V, E)

To perform DFS over a graph, the data structures required are stack (S) and the list (visited), ‘V’ is the start vertex.

Procedure for DFS(V)

Steps

1. push the start vertex 'V' into the stack S
2. while (S is not empty)
   (i) pop a vertex V
   (ii) if 'V' is not visited
      (a) visit the vertex
      (b) Store 'V' in visited
      (c) push all the adjacent vertices of 'V' in to visited
   (iii) End if
3. End while
4. Stop.

Example:

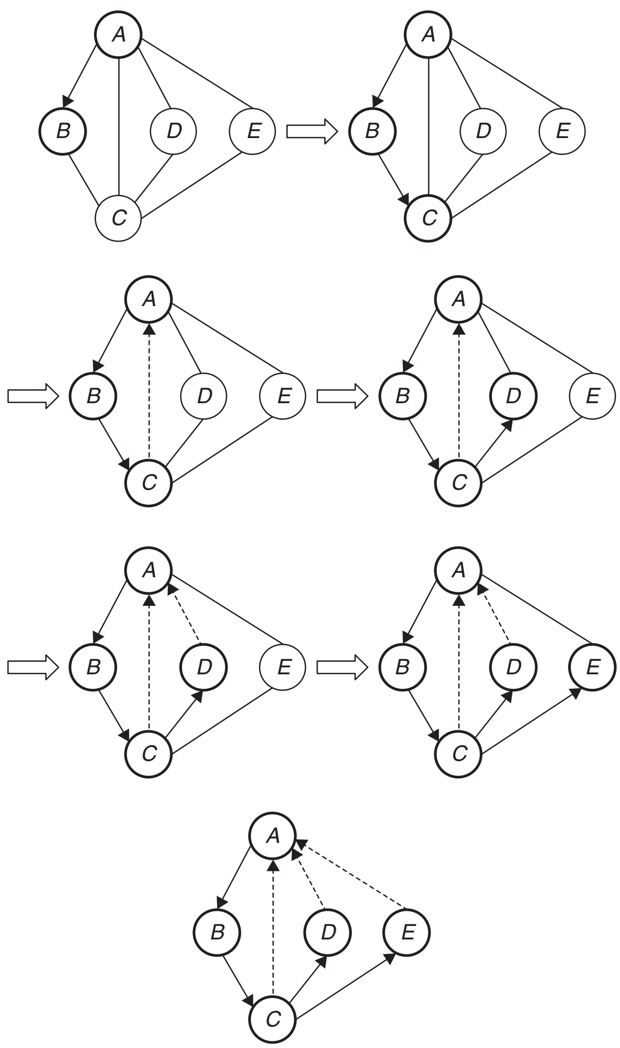

Figure 3 Depth first search

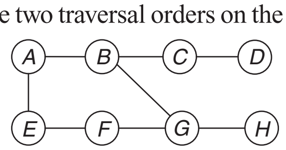
- Let us compare two traversal orders on the following graph:



Initial steps:

READY = [A]. process A. READY = [B, E]. process B.

It is at this point that two traversal strategies differ. Breadth first adds B's neighbors to the back of READY, depth first adds them to the front.

Breadth first

- READY = [E, C, G]
- Process E. READY = [C, G, F]
- Process C. READY = [G, F, D]
- Process G .READY = [F, D, H]
- Process F. READY = [D, H]
- Process D. READY = [H]
- Process H. READY = [ ]

Depth First

- READY = [C, G, E]
- Process C. READY = [D, G, E]
- Process D. READY = [G, E]
- Process G. READY = [H, F, E]
- Process H. READY = [F, E]
- Process F. READY = [E]
- Process E. READY = [ ]

Connected Components

A graph is said to be connected if every pair of vertices in the graph are connected. A connected component is a maximal connected sub graph of 'G'. Each vertex belongs to exactly one connected component as does each edge.

- A graph that is not connected is naturally and obviously decomposed into several connected components (Figure 4). Depth first search does this handily. Each restart of the algorithm marks a new connected component.
- The directed graph in (Figure 5) is "Connected" Part of it can be "Pulled apart" (so to speak, without "breaking" any edges).
- Meaningful way to define connectivity in directed graph is:

'Two nodes U and V of a directed graph $G = (V, E)$ connected if there is a path from U to V', and one from V to U. This relation between nodes is reflective, symmetric and transitive. As such, it partitions V into disjoint sets, called the strongly connected components of the graph. In the directed graph of figure 2 there are four strongly connected components.

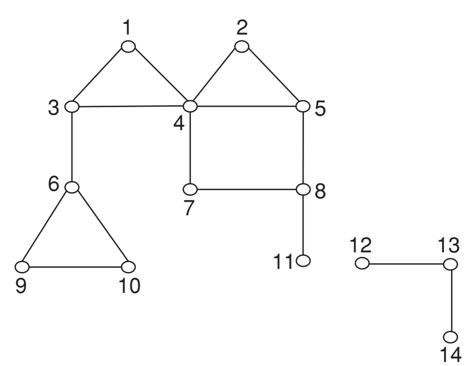


Figure 4 Undirected graph.

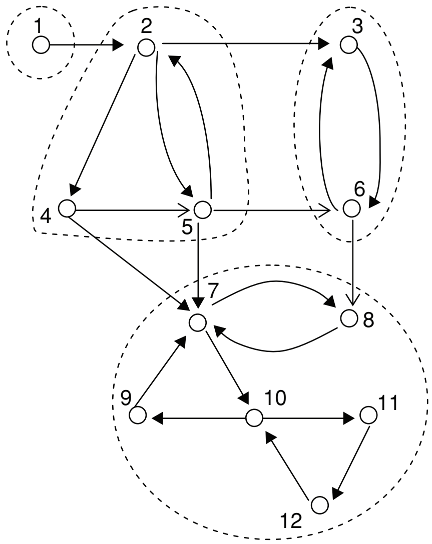

Figure 5 A directed graph and its strongly connected components

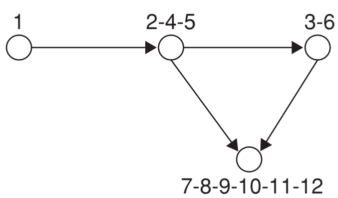
If we shrink each of these strongly connected components down to a single node and draw an edge between two of them if there is an edge from some node in the first to some node in the second, the resulting directed graph has to be a directed acyclic graph (DAG) – it has no cycles (figure 6). The reason is simple.

A cycle containing several strongly connected components would merge them all to a single strongly connected component.



Every directed graph is a DAG of its strongly connected components.

Huffman Codes

For compressing data, a very effective and widely used technique is Huffman coding. We consider the data to be a sequence of characters. Huffmans's greedy algorithm uses a table of the frequencies of occurrence of the characters to build up an optimal way of representing each character as a binary string.

Example: Suppose we have a 1,00,000 – character data file, that we wish to store compactly. The characters in the file occur with the frequencies given below:

Character	a	b	c	d	e	f
Frequency	47	12	11	14	10	6

Solution: Two methods are used for compression of data are:

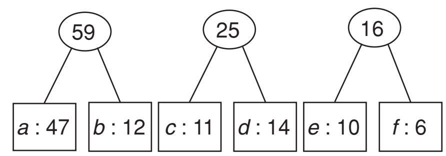
Fixed Length Coding

- Arrange all the characters in sequence (no particular order is followed)
- $a = 47, b = 12, c = 11, d = 14, e = 10, f = 6$

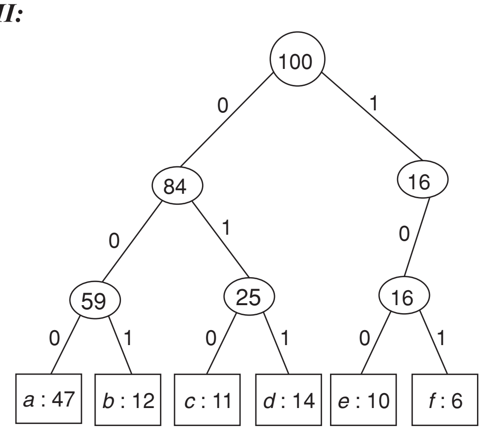
Step I:

a : 47	b : 12	c : 11	d : 14	e : 10	f : 6

Step II:



Step III:



We interpret the binary code word for a character as the path from the root to that character where '0' means 'go to the left child', and 1 means 'go to the right child'.

The above tree is not binary search tree, since the leaves need not appear in sorted order.

Constructing Huffman Code

This algorithm builds the tree T corresponding to the optimal code in a bottom-up manner. It begins with set of $|C|$ leaves and performs a sequence of $|C|$-1 'merging' operations to create the final tree.

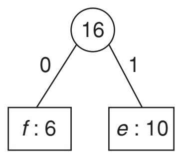
- A min-priority queue Q, keyed on f, is used to identify the 2 least – frequent objects to merge together. The result of the merger of 2 objects is a new object whose frequency is the sum of the frequencies of the 2 objects that were merged.
- In the given example, there are 6 alphabets the initial queue size is $n = 6$, and 5 merge steps are required to build the tree. The final tree represents the optimal prefix code. The code word for a letter is the sequence of edge labels on the path from the root to the letter.

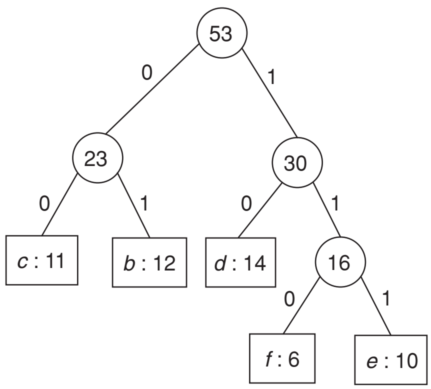
$a = 47, b = 12, c = 11, d = 14, e = 10, f = 6$

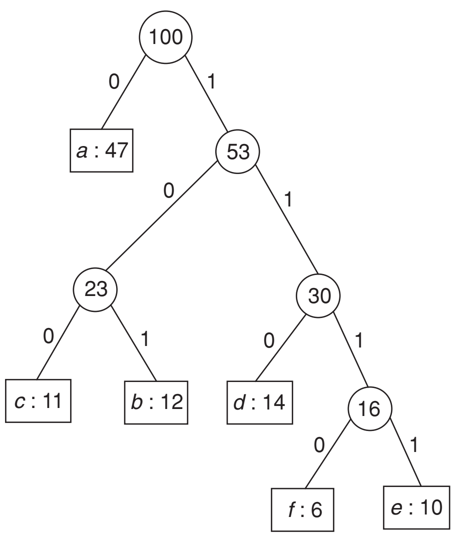
Step I: Arrange the characters in non-decreasing order according to their frequencies

f : 6	e : 10	c : 11	b : 12	d : 14	a : 47

Let x and y be 2 characters in C having the lowest frequencies. Then there exists an optimal prefix code for C in which the code words for x and y have the same length and differ only in the last bit







Analysis: The analysis of the running time of Huffman's algorithm assumes that Q is implemented as a binary min-heap for a set C of 'n' characters, the initialization of Q can be performed in $O(n)$ time using the BUILD – MIN HEAP procedure.

Each heap operation requires $O(\log n)$ time, and this will be performed exactly $(n - 1)$ times, it contributes to $O(n \log n)$ running time. Thus the total running time of HUFFMAN on a set of 'n' characters is $O(n \log n)$.

Task-scheduling problem

This is the problem of optimally scheduling unit – time tasks on a single processor, where each task has a deadline, along with a penalty that must be paid if the deadline is missed. The problem looks complicated, but it can be solved in simple manner using a greedy algorithm.

- A unit – time task is a job, such as a program to be run on a computer, that requires exactly one unit of time to complete.
- Given a finite set S of unit – time tasks, a schedule for S is a permutation of S specifying the order in which these tasks are to be performed.
- The first task in the schedule begins at time '0' and finishes at time 1, the second task begins at time 1 and finishes at time 2, and so on
- The problem of scheduling unit – time tasks with deadlines and penalties for a single processor has the following inputs:

1. A set $S = \{a_1, a_2, \ldots an\}$ of n unit – time tasks:
2. A set of n integer deadlines $d_1, d_2, \ldots d_n$ such that each d_i satisfies $1 \le d_i \le n$ and task a_i is supposed to finish by time d_i.
3. A set of n non-negative weights or penalties w_1, $w_2, \ldots w_n$, such that we incur a penalty of w_i if task a_i is not finished by time d_i and we incur no penalty if a task finishes by its deadline.

Example: Consider the following 7 tasks, T_1, T_2, T_3, T_4, T_5 T_6, T_7. Every task is associated with profit and deadline.

Tasks	T_1	T_2	T_3	T_4	T_5	T_6	T_7
Deadline	4	2	4	3	1	4	5
Profit	75	65	55	45	40	35	30

45	65	55	75	30			
T_4	T_2	T_3	T_1	T_7			
0	1	2	3	4	5	6	7

T_1 has highest profit, so it will be executed first and the deadline of T_1, is '4' so T_1 has to be executed within 4 slots of time, same procedure is applied to other tasks also.

The tasks which are not executed by CPU are T_5 and T_6.

Profit: sum up the profits made by executing the tasks. Profit = 45 + 65 + 55 + 75 + 30 = 270

Analysis: We can use a greedy algorithm to find a maximum weight independent set of tasks. We can then create an optimal schedule having the tasks in A as its early tasks.

This method is an efficient algorithm for scheduling unit – time tasks with deadlines and penalties for a single processor. The running time is $O(n^2)$ using GREEDY METHOD, since each of the $O(n)$ independent checks made by that algorithm takes time $O(n)$.

Sorting and Order Statistics

Minimum and Maximum

This algorithm determines, how many comparisons are necessary to find minimum or maximum of a set of 'n' elements. Usually we can obtain maximum or minimum, by performing

$(n - 1)$ comparisons; examine each element of the set in turn and keep track of the smallest element seen so far.

Consider the following procedure.

Assume that the set of elements reside in an array A where length $[A] = n$

MINIMUM (A)
Min $\leftarrow A[1]$
For $i \leftarrow 2$ to length $[A]$
Do if min $> A[i]$
Then min $\leftarrow A[i]$
Return min.

Simultaneous minimum and maximum

In some applications, we must find both the minimum and the maximum of a set of 'n' elements.

We can find the minimum and maximum independently using $(n - 1)$ comparisons for each, for a total of $(2n - 2)$ comparisons.

- In fact, atmost $3\lfloor n/2 \rfloor$ comparisons are sufficient to find both the minimum and the maximum.
- The strategy is to maintain the minimum and maximum elements seen so far.
- Rather than processing each element of the input by comparing it against the current minimum and maximum at a cost of 2 comparisons per element, we process elements in pairs.
- Compare pairs of elements from the input with each other, and then we compare smaller to the current minimum and the larger to the current maximum, at a cost of 3 comparisons for every 2 elements.
- Setting up initial values for the current minimum and maximum depends on whether 'n' is odd or even. If 'n' is odd, we set both the minimum and maximum to the value of the first element, and then we process the rest of the elements in pairs.
- If 'n' is even, we perform 1 comparison on the first 2 elements to determine the initial values of the minimum and maximum and then process the rest of the elements in pairs.

Analysis: If 'n' is odd the total number of comparisons would be $3\lfloor n/2 \rfloor$.

If 'n' is even, we need 1 initial comparison followed by $\frac{3(n-2)}{2}$ comparisons, for a total of $\frac{3n}{2} - 2$.

$\therefore$ The total number of comparisons is atmost $3\lfloor n/2 \rfloor$

Graph Algorithms

Single Source Shortest Path

In a shortest-path problem, we are given a weighted directed graph $G = (V, E)$ with weight function $W : E \rightarrow R$ mapping edges to real-valued weights. The weight of path $P = < V_O, V_1 \ldots V_K >$ is the sum of the weights of its constituent edges. Shortest-path weight from U to V is defined by

$$\delta(U,V) = \begin{cases} \{\min\{W(P): u \rightarrow v\} & \text{if there is a path from} \\ \infty & \text{'}U\text{' to '}V\text{' otherwise} \end{cases}$$

Edge weights can be interpreted as metrics other than distances. They are often used to represent time, cost, penalties, loss, or any other quantity.

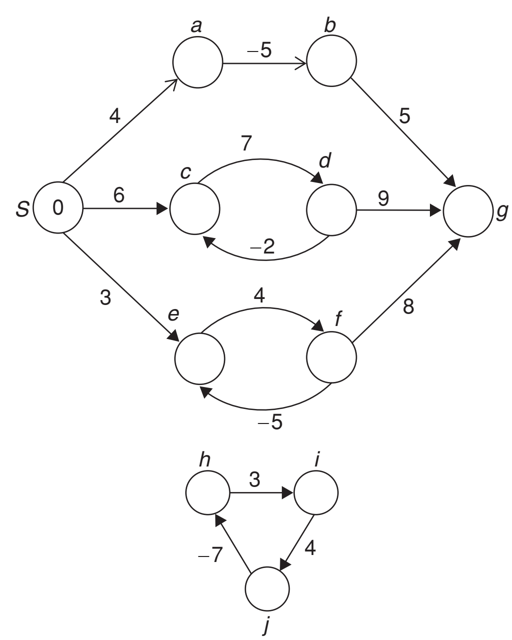
- The breadth first search algorithm is a shortest-path algorithm that works on un weighted graphs, that is, graphs in which each edge can be considered to have unit weight.

Negative-weight edges

Some of the instances of the single-source-shortest-paths problem, there may be edges whose weights are negative.

- If the graph $G = (V, E)$ contains no negative weight cycles reachable from source S, then for all $v \in V$, the shortest – path weight $d(S, V)$ remains well defined, even if it has a negative value.
- If there is a negative-weight cycle reachable from S, shortest-path weights are not well defined.
- No path from 'S' to a vertex on the cycle can be a shortest path - a lesser weight path can always be found that follows the proposed 'shortest' path and then traverses the negative-weight cycle.
- If there is a negative-weight cycle on some path form 'S' to 'V', we define $\delta(S,V) = -\infty$.

Example: Consider the following graph, calculate the shortest distance to all vertices from sources 'S'.



Solution:

- Shortest path from S to a is $\delta(S, a) = W(S, a) = 4$ (because there is only one path from 'S' to 'a')
- Similarly, there is only one path from 's' to 'b' $\delta(S, a) = W(S, a) + W(a, b) = 4 + (-5) = -1$
- Shortest-path from 's' to 'c'

There are infinitely many paths from 'S' to 'c'

1. $<S, c>$
2. $<S, c, d, c>$
3. $<S, c, d, c, d, c>$ and so on

$\delta <S, c> = 6$

$\delta (S, d, d, c) = 6 + 7 - 2 = 11$

$\delta (S, c, d, c, d, c) = 6 + 7 - 2 + 7 - 2 = 16$

$\delta (S, c, d, c, d, c, d, c)$

$= 6 + 7 - 2 + 7 - 2 + 7 - 2 = 21$

The cycle $<c, d, c>$ has weight $= 7 + (-2) = 5 > 0$

The shortest path from 'S' to 'c' is $<s, c>$ with weight $\delta (S, c) = 6$ similarly, the shortest-path from 'S' to 'd' is $<s, c, d>$, with weight $\delta (S, d) = w (S, c) + W(c, d) = 13$

May there are infinitely paths from 'S' to 'e'

1. $<s, e>$
2. $<s, e f, e>$
3. $<s, e, f, e, f, e>$ and so on

Since the cycle $<e, f, e>$ has weight $4 + (-5) = -1 < 0$. However, there is no shortest path from 'S' to 'e' by traversing the negative-weight cycle $<e, f, e>$ arbitrarily many times, we can find paths from 's' to 'e' with arbitrarily large negative weights,

So $\delta(S, e) = -\infty$

Similarly, $\delta(S, f) = -\infty$

- The shortest path from 'S' to 'g':
  'g' can be reachable from 'f'; we can also find paths with arbitrarily large negative weights from 's' to 'g' and $\delta(s, g) = -\infty$
- Vertices 'h', 'i' and 'j' also form a negative - weight cycle. They are not reachable from 'S' so, $\delta(S, h) = \delta(S, i) = \delta(S, j) = \infty$

Dijkstra's Algorithm

Dijkstra's algotithm solves the single-source shortest-path problem on a weighted, directed graph $G = (V, E)$, for the case in which all edge weights are non-negative.

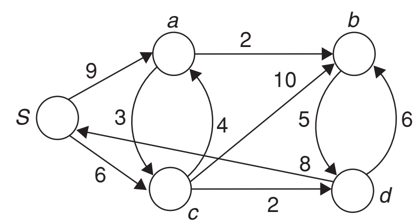
- The running time of Dijkstra's algorithm is lower than that of the Bellman–Ford algorithm.
- Dijkstra's algorithm maintains a set 's' of vertices whose final shortest-path weights from the source 'S' have already been determined.
- The algorithm repeatedly selects the vertex $u \in (V - S)$ with the minimum shortest-path estimate, adds 'u' to 'S'

DIJKSTRA (G, W, S)
INITIALIZE – SINGLE – SOURCE (G, S)
$S \leftarrow \varnothing$
$S \leftarrow V[G]$
While $Q \neq 0$
do $u \leftarrow$ EXTRACT – MIN(Q)
$S \leftarrow S \, U\{u\}$
For each vertex $v \in \text{Adj}[u]$
do RELAX (u, v, w)

The algorithm maintains the invariant that $Q = V - S$ at the start of each iteration of the while loop. Initially the min – priority queue Q contains all the vertices in V. ($\because S = \varnothing$). Each time through the while loop, a vertex 'u' is extracted from $Q = V - S$ and added to set S.

- Each vertex is extracted from Q and added to S exactly once, so the contents of while loop will be executed exactly $|v|$ times.
- Dijkstra's algorithm always chooses the 'closest' or 'lightest' vertex in $(V - S)$ to add to set S, we say that it uses a greedy strategy.

Example: Consider the following graph, what is the shortest path?



Solution:

S	V – S
S	a b c d
S c	a b d
S c d	a b
S c d a	b
S c d a b	∅

Distance from S to all vertices of $(V - S)$

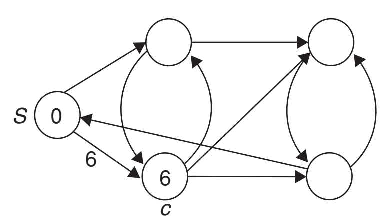
$d[a] = 9$

$d[b] = \infty$

$d[c] = 6$

$d[d] = \infty$

$9, \infty, 6, \infty$ values are given to MIN-PRIORITY Queue 'Q', '6' is returned.

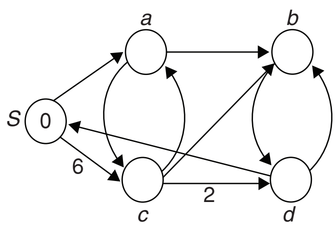


Distance from [Sc] to all vertices of $(V - S)$

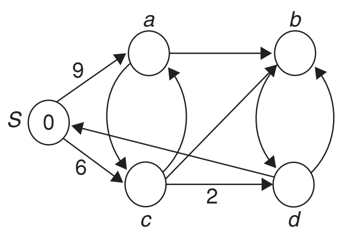
$d[b] = (S - c - b) = 6 + 10 = 16$

$d[a] = \min\{(S - a) = 9, (s - c - a) = 10\} = 9$

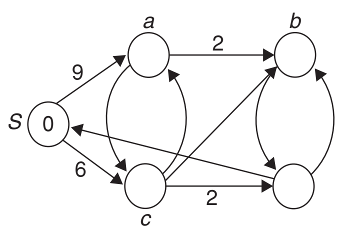
$d[d] = \min\{\infty, (S - c - d) = 6 + 2 = 8\} = 8$



Distance from [s c d] to [ab]
$d[a] = \min\{9, (S - c - d - S - a) = 25\} = 9$
$d[b] = \min\{16, (S - c - d - b) = 14\} = 14$



$d[a] = \min\{14, (s - a - b) = 9 + 2 = 11\} = 11$



Analysis: It maintains the min-priority queue 'Q' by calling three priority-queue operations: INSERT, EXTRACT-MIN, and DECREASE-KEY. We maintain the min-priority queue by taking the vertices being numbered 1 to $|v|$. We store $d[v]$ in the vth entry of an array. Each INSERT and DECREASE-KEY operation takes $O(1)$ time, and each EXTRACT- MIN operation takes $O(v)$ time ($\therefore$ we have to search through the entire array) for a total time of $O(v^2 + E) = O(v^2)$.

- If we implement the min - priority queue with a binary min-heap. Each EXTRACT-MIN operation takes time $O(\log V)$, there are $|V|$ such operations.
- The time to build the binary min-heap is $O(v)$. Each DECREASE-KEY operation takes time $O(\log V)$, and there are still atmost $|E|$ such operations. The total running time is $O((V + E) \log V)$, which is $O(E \log V)$ if all vertices are reachable form the source.
- We can achieve a running time of $O(V \log V + E)$ by implementing the min-priority queue with a Fibonacci heap.

Bellman–Ford Algorithm

Bellman–Ford algorithm solves the single-source shortest-path problems in the case in which edge weights may be negative.

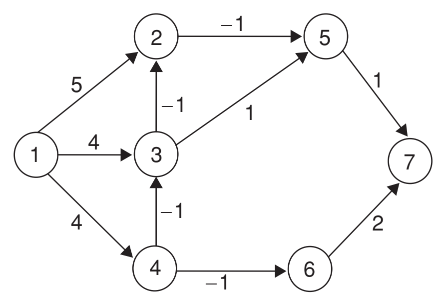
- When negative edge lengths are permitted, we require that the graph have no cycles of negative length. This is necessary to ensure that shortest-paths consist of a finite number of edges.
- When there are no cycles of negative length, there is a shortest-path between any two vertices of an n-vertex graph that has atmost $(n - 1)$ edges on it.
- A path that has more than $(n - 1)$ edges must repeat atleast one vertex and hence must contain a cycle
- Let $\text{dist}^x[u]$ be the length of a shortest-path from the source vertex 'v' to vertex 'u' under the constraint that the shortest-path contains atmost 'x' edges. Then $\text{dist}'[u] = \text{cost}[v, u]$ $1 \le u \le n$ when there are no cycles of negative length we can limit our search for shortest-paths to paths with at most $(n - 1)$ edges. Hence, $\text{dist}^{n-1}[u]$ is the length of an unrestricted shortest-path from 'v' to 'u'.

The Recurrence Relation for dist is:

$$\text{Dist}^k[u] = \min\{\text{dist}^{k-1}[u], \min\{\text{dist}^{k-1}[i] + \text{cost}[i, u]\}\}$$

This recurrence can be used to compute dist^k from dist^{k-1}, for $k = 2, 3, \ldots, n - 1$.

Example: Consider the given directed graph



Find the shortest path from vertex '1' to all other vertices using Bellman–Ford algorithm?

Solution: Source vertex is '1' the distance from '1' to '1' in all '6' iterations will be zero. Since the graph has '7' vertices, the shortest-path can have atmost '6' edges. The following figure illustrates the implementation of Bellman–Ford algorithm:

	1	2	3	4	5	6	7
1	0	5	4	4	∞	∞	∞
2	0	3	3	4	4	3	∞
3	0	2	3	4	2	3	5
4	0	2	3	4	1	3	3
5	0	2	3	4	1	3	2
6	0	2	3	4	1	3	2
7	0	2	3	4	1	3	2

Analysis

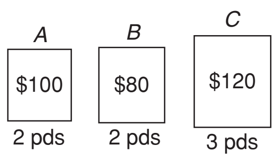
- Each iteration takes $O(n^2)$ time if adjacency matrices are used and $O(e)$ time if adjacency lists are used. Here 'e' is the number of edges in the graph.
- The time complexity is $O(n^3)$ when adjacency matrices are used and $O(N * E)$ when adjacency lists are used.

Exercises

Practice Problems 1

Directions for questions 1 to 14: Select the correct alternative from the given choices.

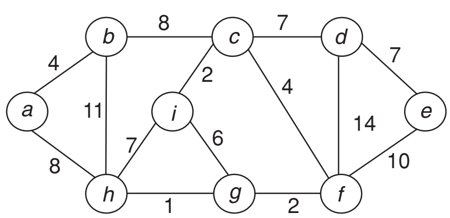
1. A thief enters a store and sees the following:



His knapsack can hold 4 pounds, what should he steal to maximize profit? (Use 0–1 Knapsack).
(A) *A* and *B* (B) *A* and *C*
(C) *B* and *C* (D) *A*, *B* and *C*

2. By using fractional Knapsack, calculate the maximum profit, for the data given in the above question?
(A) 180 (B) 170
(C) 160 (D) 150

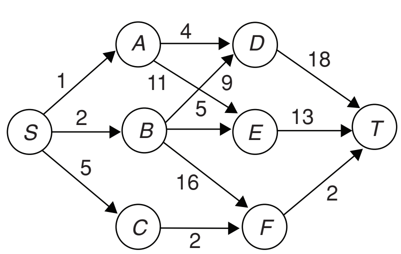
3. Consider the below figure:



What is the weight of the minimum spanning tree using Kruskals algorithm?
(A) 34 (B) 35
(C) 36 (D) 38

4. Construct a minimum spanning tree for the figure given in the above question, using prim's algorithm. What are the first three nodes, added to the solution set respectively (consider '*a*' as starting node).
(A) *b*, *c*, *i* (B) *h*, *b*, *c*
(C) *c*, *i*, *b* (D) *h*, *c*, *b*

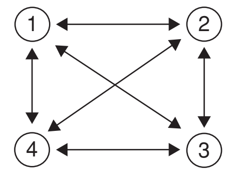
5. Consider the below graph, calculate the shortest distance from '*S*' to '*T*'?



(A) 23 (B) 9
(C) 20 (D) 22

6. Solve the travelling salesman problem, with the given distances in the form of matrix of graph, which of the following gives optimal solution?

C	1	2	3	4
1	0	15	20	25
2	10	0	14	15
3	11	18	0	17
4	13	13	14	0



(A) 1 – 2 – 4 – 3 – 1 (B) 2 – 3 – 4 – 1 – 2
(C) 1 – 4 – 2 – 3 – 1 (D) 2 – 4 – 3 – 1 – 2

7. Calculate the maximum profit using greedy strategy, knapsack capacity is 50. The data is given below:
$n = 3$
$(w_1, w_2, w_3) = (10, 20, 30)$
$(p_1, p_2, p_3) = (60, 100, 120)$ (dollars)? (0/1 knapsack)
(A) 180 (B) 220
(C) 240 (D) 260

Common data for questions 8 and 9: Given that

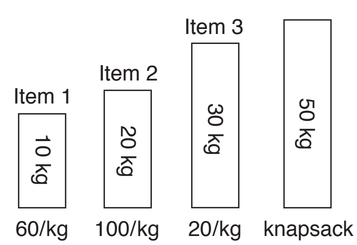
	a	b	c	d	e	f
Frequency	45	13	12	16	9	5
Fixed length code word	000	001	010	011	100	101

8. Using Huffman code, find the path length of internal nodes.
(A) 8 (B) 100
(C) 100 × 8 (D) 100/8

9. Using above answer, external path length will be
(A) 18 (B) 108
(C) 8 (D) None of these

Common data for questions 10 and 11:

10.



Using 0–1 knapsack select a subset of the three items shown, whose weight must not exceed 50 kg. What is the value?
(A) 2220 (B) 2100
(C) 2600 (D) 2180

11. Which of the following gives maximum profit, using fractional knapsack?
(A) $x_1 = 1, x_2 = 1, x_3 = 0$ (B) $x_1 = 1, x_2 = 1, x_3 = 2/3$
(C) $x_1 = 1, x_2 = 0, x_3 = 1$ (D) $x_1 = 1, x_2 = 1, x_3 = 1/3$

12. Using dynamic programming find the longest common subsequence (LCS) in the given 2 sub sequences:

x [1, … , m]
y [1, … , n]
x : A B C B D A B
Y : B D C A B A

Find longest sequence sets common to both.
(A) (BDAB, BCAB, BCBA)
(B) (BADB, BCAB, BCBA)
(C) (BDAB, BACB, BCBA)
(D) (BDAB, BCAB, BBCA)

13. Let C_1, C_2, C_3, C_4 represent coins.

C_1 = 25 paisa
C_2 = 10 paisa
C_3 = 5 paisa
C_4 = 1 paisa

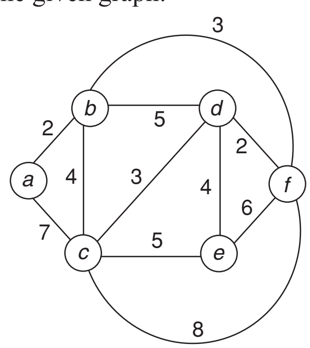
To represents 48 paisa, what is the minimum number of coins used, using greedy approach?
(A) 6 (B) 7
(C) 8 (D) 9

14. Worst-case analysis of hashing occurs when
(A) All the keys are distributed
(B) Every key hash to the same slot
(C) Key values with even number, hashes to slots with even number
(D) Key values with odd number hashes to slots with odd number.

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

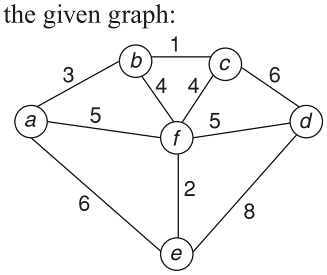
1. Consider the given graph:



Which one of the following cannot be the sequence of edges added, in that order, to a minimum spanning tree using Kruskal's algorithm?
(A) $(a-b)$, $(d-f)$, $(b-f)$, $(d-c)$, $(d-e)$
(B) $(a-b)$, $(d-f)$, $(d-c)$, $(b-f)$, $(d-e)$
(C) $(d-f)$, $(a-b)$, $(d-c)$, $(b-f)$, $(d-e)$
(D) $(d-f)$, $(a-b)$, $(b-f)$, $(d-e)$, $(d-c)$

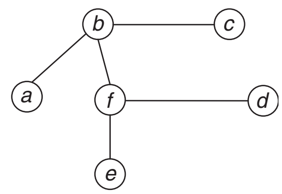
2. The worst case height analysis of B-tree is
(A) $O(n)$
(B) $O(n^2)$
(C) $O(\log n)$
(D) $O(n \log n)$

3. Consider the given graph:

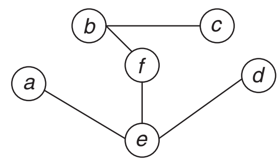


Which of the following is the minimum spanning tree. (If we apply Kruskal algorithm).

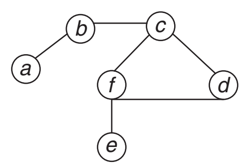
(A)



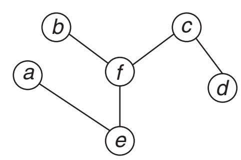
(B)



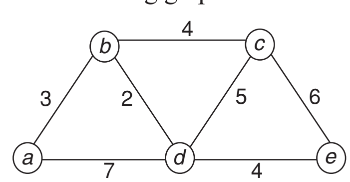
(C)



(D)



4. Consider the following graph:



Find the shortest path using Dijkstra's algorithm.
(A) a – b – d – e (B) a – b – c – d
(C) a – c – d – e (D) a – b – c – e

5. Which statement is true about Kruskal's algorithm?
(A) It is a greedy algorithm for the minimum spanning tree problem.
(B) It constructs spanning tree by selecting edges in increasing order of their weights.
(C) It does not accept creation of cycles in spanning tree.
(D) All the above

6. Dijkstra's algorithm bears similarity to which of the following for computing minimum spanning trees?
(A) Breadth first search (B) Prim's algorithm
(C) Both (A) and (B) (D) None of these

7. Which of the following algorithm always yields a correct solution for a graph with non-negative weights to compute shortest paths?
(A) Prim's algorithm (B) Kruskal's algorithm
(C) Dijkstra's algorithm (D) Huffman tree

8. Let the load factor of the hash table is number of keys is n, cells of the hash table is m then

(A) $\propto = n/m$ (B) $\propto = m/n$
(C) $\propto \dfrac{m+1}{n}$ (D) $\propto \dfrac{n+1}{m}$

9. To implement Dijkstra's shortest path algorithm on unweighted graphs so that it runs in linear time, the data structure to be used is:
(A) Queue
(B) Stack
(C) Heap
(D) B-tree

10. The development of a dynamic-programming algorithm can be broken into a sequence of four steps, which are given below randomly.
I. Construct an optimal solution from computed information.
II. Compute the value of an optimal solution in a bottom-up fashion.
III. Characterize the structure of an optimal solution.
IV. Recursively defines the value of an optimal solution.

The correct sequence of the above steps is
(A) I, II, III, IV (B) IV, III, I, II
(C) IV, II, I, III (D) III, IV, II I

11. Let V stands for vertex, E stands for edges.

For both directed and undirected graphs, the adjacency list representation has the desirable property that the amount of memory required is
(A) $\theta(V)$ (B) $\theta(E)$
(C) $\theta(V+E)$ (D) $\theta(V-E)$

12. Which of the following is false?
(A) Adjacency-matrix representation of a graph permits faster edge look up.
(B) The adjacency matrix of a graph requires $\theta(v^2)$ memory, independent of the number of edges in the graph.
(C) Adjacency-matrix representation can be used for weighted graphs.
(D) All the above

13. Dynamic programming is a technique for solving problems with
(A) Overlapped sub problems
(B) Huge size sub problems
(C) Small size sub problems
(D) None of these

14. The way a card game player arranges his cards, as he picks them up one by one is an example of _____.
(A) Bubble sort (B) Selection sort
(C) Insertion sort (D) None of the above

15. You want to check whether a given set of items is sorted. Which method will be the most efficient if it is already in sorted order?
(A) Heap sort (B) Bubble sort
(C) Merge sort (D) Insertion sort

Previous Years' Questions

Data for question 1: We are given 9 tasks $T_1, T_2 \ldots T_9$. The execution of each task requires one unit of time. We can execute one task at a time. Each task T_i has a profit P_i and a deadline D_i. Profit P_i is earned if the task is completed before the end of the D_ith unit of time.

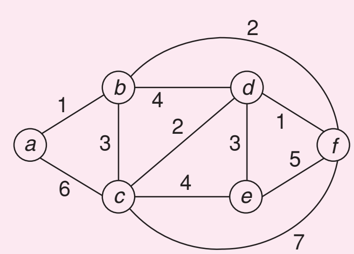
Task	T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9
Profit	15	20	30	18	18	10	23	16	25
Deadline	7	2	5	3	4	5	2	7	3

1. What is the maximum profit earned? **[2005]**
(A) 147 (B) 165
(C) 167 (D) 175

2. Consider a weighted complete graph G on the vertex set $\{v_1, v_2, \ldots, v_n\}$ such that the weight of the edge (v_i, v_j) is $2|i-j|$. The weight of the minimum spanning tree is: **[2006]**
(A) $n-1$ (B) $2n-2$
(C) $\binom{n}{2}$ (D) n^2

3. To implement Dijkstra's shortest path algorithm on unweighted graphs so that it runs in linear time, the data structure to be used is: **[2006]**
(A) Queue
(B) Stack
(C) Heap
(D) B-Tree

4. Consider the following graph: **[2006]**



Which one of the following cannot be the sequence of edges added, in that order, to a minimum spanning tree using Kruskal's algorithm?

(A) (a – b), (d – f), (b – f), (d – c), (d – e)
(B) (a – b), (d – f), (d – c), (b – f), (d – e)
(C) (d – f), (a – b), (d – c), (b – f), (d – e)
(D) (d – f), (a – b), (b – f), (d – e), (d – c)

Common data for questions 5 and 6: A 3-ary max-heap is like a binary max-heap, but instead of 2 children, nodes have 3 children. A 3-ary heap can be represented by an array as follows: The root is stored in the first location, $a[0]$, nodes in the next level, from left to right, is stored from $a[1]$ to $a[3]$. The nodes from the second level of the tree from left to right are stored from $a[4]$ location onward. An item x can be inserted into a 3-ary heap containing n items by placing x in the location $a[n]$ and pushing it up the tree to satisfy the heap property.

5. Which one of the following is a valid sequence of elements in an array representing 3-ary max-heap? **[2006]**

(A) 1, 3, 5, 6, 8, 9 (B) 9, 6, 3, 1, 8, 5
(C) 9, 3, 6, 8, 5, 1 (D) 9, 5, 6, 8, 3, 1

6. Suppose the elements 7, 2, 10 and 4 are inserted, in that order, into the valid 3-ary max-heap found in the above question, Q-76. Which one of the following is the sequence of items in the array representing the resultant heap? **[2006]**

(A) 10, 7, 9, 8, 3, 1, 5, 2, 6, 4
(B) 10, 9, 8, 7, 6, 5, 4, 3, 2, 1
(C) 10, 9, 4, 5, 7, 6, 8, 2, 1, 3
(D) 10, 8, 6, 9, 7, 2, 3, 4, 1, 5

7. In an unweighted, undirected connected graph, the shortest path from a node S to every other node is computed most efficiently, in terms of *time complexity*, by **[2007]**

(A) Dijkstra's algorithm starting from S.
(B) Warshall's algorithm
(C) Performing a DFS starting from S.
(D) Performing a BFS starting from S.

8. A complete n-ary tree is a tree in which each node has n children or no children. Let I be the number of internal nodes and L be the number of leaves in a complete n-ary tree. If $L = 41$, and $I = 10$, what is the value of n? **[2007]**

(A) 3 (B) 4
(C) 5 (D) 6

9. Consider the following C program segment where CellNode represents a node in a binary tree: **[2007]**

```
struct CellNode {
  struct CellNode *leftChild;
     int element;
   struct CellNode *rightChild;
};
```

```
int GetValue (struct CellNode *ptr) {
   int value = 0;
   if (ptr != NULL) {
       if ((ptr->leftChild == NULL) &&
            (ptr->rightChild == NULL))
          value = 1;
   else
  value = value + GetValue(ptr->leftChild)
           + GetValue(ptr->rightChild);
     }
  return(value);
```

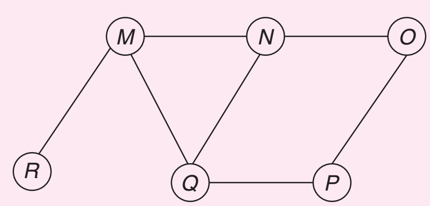
The value returned by GetValue when a pointer to the root of a binary tree is passed as its argument is:

(A) The number of nodes in the tree
(B) The number of internal nodes in the tree
(C) The number of leaf nodes in the tree
(D) The height of the tree

10. Let w be the minimum weight among all edge weights in an undirected connected graph. Let e be a specific edge of weight w. Which of the following is FALSE? **[2007]**

(A) There is a minimum spanning tree containing e.
(B) If e is not in a minimum spanning tree T, then in the cycle formed by adding e to T, all edges have the same weight.
(C) Every minimum spanning tree has an edge of weight w.
(D) e is present in every minimum spanning tree.

11. The Breadth first search algorithm has been implemented using the queue data structure. One possible order of visiting the nodes of the following graph is **[2008]**



(A) MNOPQR (B) NQMPOR
(C) QMNPRO (D) QMNPOR

12. G is a graph on n vertices and $2n - 2$ edges. The edges of G can be partitioned into two edge-disjoint spanning trees. Which of the following is NOT true for G? **[2008]**

(A) For every subset of k vertices, the induced subgraph has atmost $2k - 2$ edges
(B) The minimum cut in G has atleast two edges
(C) There are two edge-disjoint paths between every pair of vertices
(D) There are two vertex-disjoint paths between every pair of vertices

13.

Dijkstra's single source shortest path algorithm when run from vertex a in the above graph, computes the correct shortest path distance to **[2008]**

(A) Only vertex *a*
(B) Only vertices *a*, *e*, *f*, *g*, *h*
(C) Only vertices *a*, *b*, *c*, *d*
(D) all the vertices

14. You are given the post-order traversal, *P*, of a binary search tree on the n elements 1, 2,…, *n*. You have to determine the unique binary search tree that has *P* as its post-order traversal. What is the time complexity of the most efficient algorithm for doing this? **[2008]**

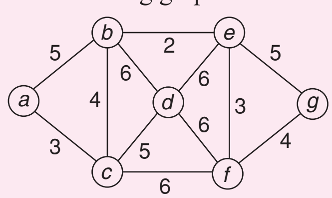
(A) $\Theta(\log n)$
(B) $\Theta(n)$
(C) $\Theta(n \log n)$
(D) None of the above, as the tree cannot be uniquely determined

15. Which of the following statement(*s*) is/are correct regarding Bellman–Ford shortest path algorithm? **[2009]**

P. Always finds a negative weighted cycle, if one exists.
Q. Finds whether any negative weighted cycle is reachable from the source.

(A) P only (B) Q only
(C) Both P and Q (D) Neither P nor Q

16. Consider the following graph: **[2009]**



Which one of the following is NOT the sequence of edges added to the minimum spanning tree using Kruskal's algorithm? **[2009]**

(A) (b, e) (e, f) (a, c) (b, c) (f, g) (c, d)
(B) (b, e) (e, f) (a, c) (f, g) (b, c) (c, d)
(C) (b, e) (a, c) (e, f) (b, c) (f, g) (c, d)
(D) (b, e) (e, f) (b, c) (a, c) (f, g) (c, d)

Common data for questions 17 and 18: Consider a binary max-heap implemented using an array.

17. Which one of the following array represents a binary max-heap? **[2009]**

(A) {25, 12, 16, 13, 10, 8, 14}
(B) {25, 14, 13, 16, 10, 8, 12}
(C) {25, 14, 16, 13, 10, 8, 12}
(D) {25, 14, 12, 13, 10, 8, 16}

18. What is the content of the array after two delete operations on the correct answer to the previous question? **[2009]**

(A) {14, 13, 12, 10, 8} (B) {14, 12, 13, 8, 10}
(C) {14, 13, 8, 12, 10} (D) {14, 13, 12, 8, 10}

Common data for questions 19 and 20: Consider a complete undirected graph with vertex set {0, 1, 2, 3, 4}. Entry W_{ij} in the matrix W below is the weight of the edge $\{i, j\}$.

$$W = \begin{pmatrix} 0 & 1 & 8 & 1 & 4 \\ 1 & 0 & 12 & 4 & 9 \\ 8 & 12 & 0 & 7 & 3 \\ 1 & 4 & 7 & 0 & 2 \\ 4 & 9 & 3 & 2 & 0 \end{pmatrix}$$

19. What is the minimum possible weight of a spanning tree *T* in this graph such that vertex 0 is a leaf node in the tree *T*? **[2010]**

(A) 7 (B) 8
(C) 9 (D) 10

20. What is the minimum possible weight of a path *P* from vertex 1 to vertex 2 in this graph such that *P* contains at most 3 edges? **[2010]**

(A) 7 (B) 8
(C) 9 (D) 10

Common data for questions 21 and 22: A hash table of length 10 uses open addressing with hash function $h(k) = k \bmod 10$, and linear probing. After inserting 6 values into an empty hash table, the table is as shown below:

0	
1	
2	42
3	23
4	34
5	52
6	46
7	33
8	
9	

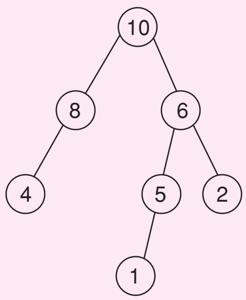
21. Which one of the following choices gives a possible order in which the key values could have been inserted in the table? **[2010]**

(A) 46, 42, 34, 52, 23, 33
(B) 34, 42, 23, 52, 33, 46
(C) 46, 34, 42, 23, 52, 33
(D) 42, 46, 33, 23, 34, 52

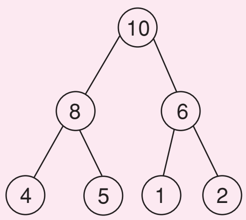
22. How many different insertion sequences of the key values using the same hash function and linear probing will result in the hash table shown above? **[2010]**
(A) 10 (B) 20
(C) 30 (D) 40

23. A max-heap is a heap where the value of each parent is greater than or equal to the value of its children. Which of the following is a max-heap? **[2011]**

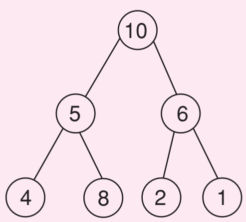
(A)



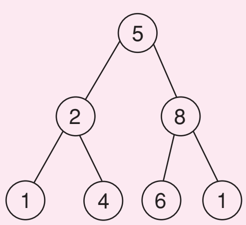
(B)



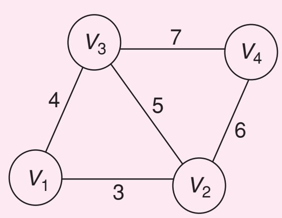
(C)



(D)



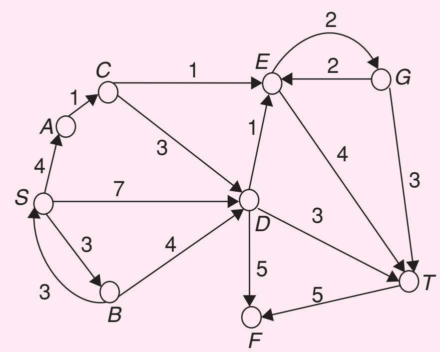
Common data for questions 24 and 25: An undirected graph $G(V, E)$ contains $n(n > 2)$ nodes named $V_1, V_2, \ldots, V_n$. Two nodes V_i, V_j are connected if and only if $0 < |i - j| \leq 2$. Each edge (V_i, V_j) is assigned a weight $i + j$. A sample graph with $n = 4$ is shown below.



24. What will be the cost of the minimum spanning tree (MST) of such a graph with n nodes? **[2011]**
(A) $\frac{1}{12}(11n^2 - 5n)$ (B) $n^2 - n + 1$
(C) $6n - 11$ (D) $2n + 1$

25. The length of the path from V_5 to V_6 in the MST of previous question with $n = 10$ is **[2011]**
(A) 11 (B) 25
(C) 31 (D) 41

26. Consider the directed graph shown in the figure below. There are multiple shortest paths between vertices S and T. Which one will be reported by Dijkstra's shortest path algorithm? Assume that, in any iteration, the shortest path to a vertex v is updated only when a strictly shorter path to v is discovered. **[2012]**



(A) SDT (B) SBDT
(C) SACDT (D) SACET

27. Let G be a weighted graph with edge weights greater than one and G^1 be the graph constructed by squaring the weights of edges in G. Let T and T^1 be the minimum spanning trees of G and G^1, respectively, with total weights t and t^1. Which of the following statements is **TRUE**? **[2012]**
(A) $T^1 = T$ with total weight $t^1 = t^2$
(B) $T^1 = T$ with total weight $t^1 < t^2$
(C) $T^1 \neq T$ but total weight $t^1 = t^2$
(D) None of the above

28. What is the time complexity of Bellman–Ford single-source shortest path algorithm on a complete graph of n vertices? **[2013]**
(A) $\Theta(n^2)$ (B) $\Theta(n^2 \log n)$
(C) $\Theta(n^3)$ (D) $\Theta(n^3 \log n)$

29. Consider the following operation along with Enqueue and Dequeue operations on queues, where k is a global parameter.

```
MultiDequeue(Q) {
m = k
```

```
while (Q is not empty) and (m > 0) {
          Dequeue (Q)
          m = m - 1
    }
}
```

What is the worst case time complexity of a sequence of n queue operations on an initially empty queue? **[2013]**

(A) $\Theta(n)$ (B) $\Theta(n + k)$
(C) $\Theta(nk)$ (D) $\Theta(n^2)$

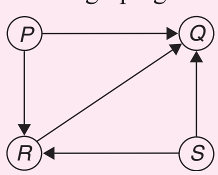
30. The preorder traversal sequence of a binary search tree is 30, 20, 10, 15, 25, 23, 39, 35, 42. Which one of the following is the post order traversal sequence of the same tree? **[2013]**

(A) 10, 20, 15, 23, 25, 35, 42, 39, 30
(B) 15, 10, 25, 23, 20, 42, 35, 39, 30
(C) 15, 20, 10, 23, 25, 42, 35, 39, 30
(D) 15, 10, 23, 25, 20, 35, 42, 39, 30

31. Let G be a graph with n vertices and m edges. What is the tightest upper bound on the running time of depth first search on G, when G is represented as an adjacency matrix? **[2014]**

(A) $\theta(n)$ (B) $\theta(n + m)$
(C) $\theta(n^2)$ (D) $\theta(m^2)$

32. Consider the directed graph given below. **[2014]**



Which one of the following is TRUE?

(A) The graph does not have any topological ordering.
(B) Both PQRS and SRQP are topological orderings.
(C) Both PSRQ and SPRQ are topological orderings.
(D) PSRQ is the only topological ordering.

33. There are 5 bags labeled 1 to 5. All the coins in a given bag have the same weight. Some bags have coins of weight 10 gm. Others have coins of weight 11 gm. I pick 1, 2, 4, 8, 16 coins respectively from bags 1 to 5. Their total weight comes out to 323 gm. Then the product of the labels of the bags having 11 gm coins is ___ **[2014]**

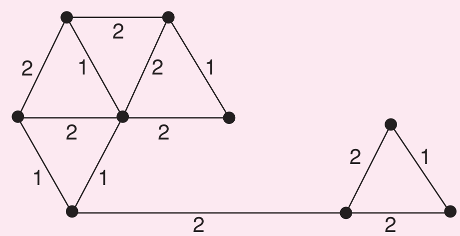
34. A priority queue is implemented as a max-heap. Initially it has 5 elements. The level-order traversal of the heap is : 10, 8, 5, 3, 2. Two new elements 1 and 7 are inserted into the heap in that order. The level-order traversal of the heap after the insertion of the elements is **[2014]**

(A) 10, 8, 7, 3, 2, 1, 5 (B) 10, 8, 7, 2, 3, 1, 5
(C) 10, 8, 7, 1, 2, 3, 5 (D) 10, 8, 7, 5, 3, 2, 1

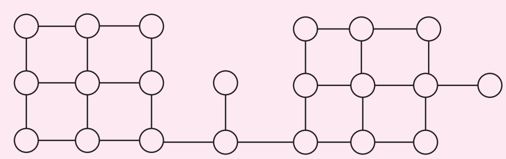
35. Consider the tree arcs of a BFS traversal from a source node W in an unweighted, connected, undirected graph. The tree T formed by the tree acrs is a data structure for computing **[2014]**

(A) The shortest path between every pair of vertices
(B) The shortest path from W to every vertex in the graph
(C) The shortest paths from W to only those nodes that are leaves of T.
(D) The longest path in the graph

36. The number of distinct minimum spanning trees for the weighted graph below is _______. **[2014]**

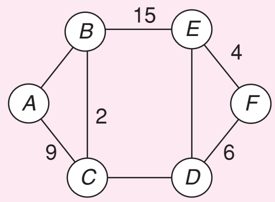


37. Suppose depth first search is executed on the graph below starting at some unknown vertex. Assume that a recursive call to visit a vertex is made only after first checking that the vertex has not been visited earlier. Then the maximum possible recursion depth (Including the initial call) is _______. **[2014]**



38. Suppose we have a balanced binary search tree T holding n numbers. We are given two numbers L and H and wish to sum up all the numbers in T that lie between L and H. suppose there are m such numbers in T. If the tightest upper bound on the time to compute the sum is $O(n^a \log^b n + m^c \log^d n)$, the value of $a + 10b + 100c + 1000d$ is ———. **[2014]**

39. The graph shown below has 8 edges with distinct integer edge weights. The minimum spanning tree (MST) is of weight 36 and contains the edges: $\{(A, C), (B, C), (B, E), (E, F), (D, F)\}$. The edge weights of only those edges which are in the MST are given in the figure shown below. The minimum possible sum of weights of all 8 edges of this graph is _______ **[2015]**



40. Consider two decision problems Q_1, Q_2 such that Q_1 reduces in polynomial time to 3-SAT and 3-SAT reduces in polynomial time to Q_2. Then which one of the following is consistent with the above statement? **[2015]**

(A) Q_1 is in NP, Q_2 is NP hard.
(B) Q_2 is in NP, Q_1 is NP hard.
(C) Both Q_1 and Q_2 are in NP.
(D) Both Q_1 and Q_2 are NP hard.

41. Given below are some algorithms, and some algorithm design paradigms.

1. Dijkstra's Shortest Path	i. Divide and Conquer
2. Floyd-Warshall algorithm to compute all pairs shortest path	ii. Dynamic Programming
3. Binary search on a sorted array	iii. Greedy design
4. Backtracking search on a graph	iv. Depth-first search
	v. Breadth-first search

Match the above algorithms on the left to the corresponding design paradigm they follow.

(A) 1–i, 2–iii, 3–i, 4–v
(B) 1–iii, 2–iii, 3–i, 4–v
(C) 1–iii, 2–ii, 3–i, 4–iv
(D) 1–iii, 2–ii, 3–i, 4–v

42. A Young tableau is a 2D array of integers increasing from left to right and from top to bottom. Any unfilled entries are marked with ∞, and hence there cannot be any entry to the right of, or below a ∞. The following Young tableau consists of unique entries.

1	2	5	14
3	4	6	23
10	12	18	25
31	∞	∞	∞

When an element is removed from a Young tableau, other elements should be moved into its place so that the resulting table is still a Young tableau (unfilled entries maybe filled in with a ∞). The minimum number of entries (other than 1) to be shifted, to remove 1 from the given Young tableau is _______ **[2015]**

43. Which one of the following hash functions on integers will distribute keys most uniformly over 10 buckets numbered 0 to 9 for i ranging from 0 to 2020? **[2015]**

(A) $h(i) = i^2 \bmod 10$
(B) $h(i) = i^3 \bmod 10$
(C) $h(i) = (11 * i^2) \bmod 10$
(D) $h(i) = (12 * i) \bmod 10$

44. Let G be a weighted connected undirected graph with distinct positive edge weights. If every edge weight is increased by the same value, then which of the following statements is/are TRUE? **[2016]**

P : Minimum spanning tree of G does not change.

Q : Shortest path between any pair of vertices does not change.

(A) P only
(B) Q only
(C) Neither P nor Q
(D) Both P and Q

45. Let G be a complete undirected graph on 4 vertices, having 6 edges with weights being 1,2,3,4,5, and 6. The maximum possible weight that a minimum weight spanning tree of G can have is _____ . **[2016]**

46. G = (V,E) is an undirected simple graph in which each edge has a distinct weight, and e is a particular edge of G. Which of the following statements about the minimum spanning trees (MSTs) of G is/ are **TRUE**? **[2016]**

I. If e is the lightest edge of some cycle in G, then every MST of G includes e

II. If e is the heaviest edge of some cycle in G, then every MST of G excludes e

(A) I only
(B) II only
(C) both I and II
(D) neither I nor II

47. Breadth First Search (BFS) is started on a binary tree beginning from the root vertex. There is a vertex t at a distance four from the root. If t is the n-th vertex in this **BFS** traversal, then the maximum possible value of n is _____. **[2016]**

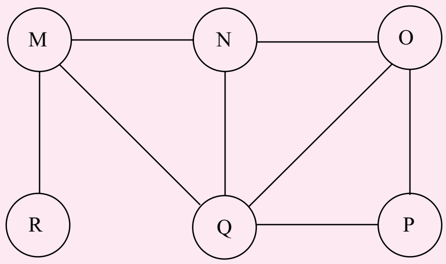
48. Let $G = (V,E)$ be *any* connected undirected edge-weighted graph. The weights of the edges in E are positive and distinct. Consider the following statements:

(I) Minimum spanning Tree of G is always unique.
(II) Shortest path between any two vertices of G is always unique.

Which of the above statements is/are necessarily true? **[2017]**

(A) (I) only
(B) (II) only
(C) both (I) and (II)
(D) neither (I) nor (II)

49. The Breadth First Search (BFS) algorithm has been implemented using the queue data structure. Which one of the following is a possible order of visiting the nodes in the graph below? **[2017]**



(A) MNOPQR
(B) NQMPOR
(C) QMNROP
(D) POQNMR

50. A message is made up entirely of characters from the set $X = \{P, Q, R, S, T\}$. The table of probabilities for each of the characters is shown below:

Character	Probability
P	0.22
Q	0.34
R	0.17
S	0.19
T	0.08
Total	1.00

If a message of 100 characters over X is encoded using Huffman coding, then the expected length of the encoded message in bits is ________. **[2017]**

51. Let G be a simple undirected graph. Let T_D be a depth first search tree of G. Let T_B be a breadth first search tree of G.

Consider the following statements.

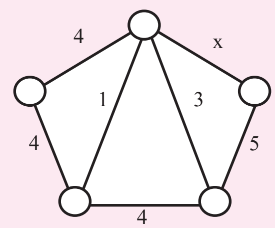
(I) No edge of G is a cross edge with respect to T_D. (A cross edge in G is between two nodes neither of which is an ancestor of the other in T_D.)

(II) For every edge (u, v) of G, if u is at depth i and v is at depth j in T_B, then $|i - j| = 1$.

Which of the statements above must necessarily be true? **[2018]**

(A) I only (B) II only
(C) Both I and II (D) Neither I nor II

52. Consider the following undirected graph G:



Choose a value for x that will maximize the number of minimum weight spanning trees (MWSTs) of G. The number of MWSTs of G for this value of x is ______. **[2018]**

Chapter 5

Dynamic Programming

LEARNING OBJECTIVES

- *Dynamic programming*
- *Multi-stage graph*
- *All pairs shortest path problem*
- *Hashing methods*
- *Mid-square method*
- *Folding method*
- *Resolving collisions*
- *Matrix chain multiplication*
- *Longest common subsequence*
- *Optimal substructure of LCS*
- *NP-hard and NP-complete*
- *P-problem*
- *NP-problem*
- *P, NP, and Co-NP*
- *Cooks theorem*
- *Non-deterministic search*

Dynamic Programming

Dynamic programming is a method for solving complex problems by breaking them down into simpler sub problems. It is applicable to problems exhibiting the properties of overlapping sub problems which are only slightly smaller, when applicable; the method takes far less time than naive method.

- The key idea behind dynamic programming is to solve a given problem, we need to solve different parts of the problem (sub problems) then combine the solutions of the sub problems to reach an overall solution. Often, many of these sub problems are the same.
- The dynamic programming approach seeks to solve each sub problem only once, thus reducing the number of computations. This is especially useful when the number of repeating sub problems is exponentially large.
- There are two key attributes that a problem must have in order for dynamic programming to be applicable 'optimal sub structure' and 'overlapping sub-problems'. However, when the overlapping problems are much smaller than the original problem, the strategy is called 'divide-and-conquer' rather than 'dynamic programming'. This is why merge sort-quick sort are not classified as dynamic programming problems.

Dynamic programming is applied for:
- Multi stage graph
- All pairs shortest path

Principle of Optimality

It states that whatever the initial state is, remaining decisions must be optimal with regard to the state following from the first decision.

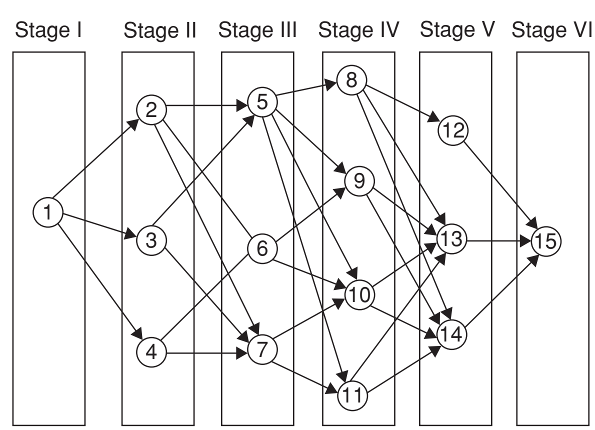
To solve a problem using dynamic programming strategy, it must observe the principle of optimality.

Multi-stage Graph

A multi-stage graph is a graph

- $G = (V, E)$ with V partitioned into $K >= 2$ disjoint subsets such that if (a, b) is in E, then a is in V_i, and b is in V_{i+1} for some sub sets in the partition;
- $|V_1| = |V_K| = 1$ the vertex S in V_1 is called the source; the vertex t is called the sink.
- G is usually assumed to be a weighted graph.
- The cost of a path from node V to node W is sum of the costs of edges in the path.
- The 'multi-stage graph problem' is to find the minimum cost path from S to t.

Example:



Costs of edges

$1 - 2 \rightarrow 10$

$1 - 3 \rightarrow 20$

1 – 4	$\rightarrow$	30
2 – 5	$\rightarrow$	10
2 – 6	$\rightarrow$	20
2 – 7	$\rightarrow$	30
3 – 5	$\rightarrow$	40
3 – 7	$\rightarrow$	50
4 – 6	$\rightarrow$	40
4 – 7	$\rightarrow$	30
5 – 8	$\rightarrow$	10
5 – 9	$\rightarrow$	20
5 – 10	$\rightarrow$	30
5 – 11	$\rightarrow$	40
6 – 9	$\rightarrow$	20
6 – 10	$\rightarrow$	30
7 – 10	$\rightarrow$	30
7 – 11	$\rightarrow$	20
8 – 12	$\rightarrow$	10
8 – 13	$\rightarrow$	20
8 – 14	$\rightarrow$	30
9 – 13	$\rightarrow$	20
9 – 14	$\rightarrow$	10
10 – 13	$\rightarrow$	10
10 – 14	$\rightarrow$	20
11 – 13	$\rightarrow$	10
11 – 14	$\rightarrow$	30
12 – 15	$\rightarrow$	20
13 – 15	$\rightarrow$	10
14 – 15	$\rightarrow$	30

Solution Using Backward Cost

Format: COST (Stage, node) = minimum cost of travelling to the node in stage from the source node (node 1)

Step I:

Cost (I, 1) = 0

Step II:

Cost (II, 2) = cost (I, 1) + cost (1, 2) = 0 + 10 = 10
Cost (II, 3) = cost (I, 1) + cost (1, 3) = 0 + 20 = 20
Cost (II, 4) = cost (I, 1) + cost (1, 4) = 0 + 30 = 30

Step III:

Cost (III, 5) = min {cost (II, 2) + cost (2, 5),
cost (II, 3) + cost (3, 5),
cost (II, 4) + cost (4, 5)
= min $\{10 + 10, 20 + 40, 30 + \infty\}$
= 20 $\rightarrow$ Via path 1 – 2 – 5

Cost (III, 6) = min {cost (II, 2) + cost (2, 6),
cost (II, 3) + cost (3, 6),
cost (II, 4) + cost (4, 6)}
= min $\{10 + 20, 20 + \infty, 30 + 40\}$
= 30 $\rightarrow$ via the path 1 – 2 – 6

Cost (III, 7) = min {cost(II, 2) + cost (2, 7),
Cost (II, 3) + cost (3, 7),
Cost (II, 4) + cost (4, 7)}
= min {10 + 30, 20 + 50, 30 + 30}
= 40 $\rightarrow$ Via the path 1 – 2 – 7

Step IV:

Cost (IV, 8) = min {cost (III, 5) + cost (5, 8),
Cost (III, 6) + cost (6, 8),
Cost (III, 7) + cost (7, 8)}
= min $\{20 + 10, 30 + \infty, 40 + \infty\}$
= 30 $\rightarrow$ Via path 1 – 2 – 5 – 8

Cost (IV, 9) = min {cost (III, 5) + cost (5, 9),
Cost (III, 6) + cost (6, 9),
Cost (III, 7) + cost (7, 9)}
= min $\{20 + 20, 30 + 20, 40 + \infty\}$
= 40 $\rightarrow$ Via the path 1 – 2 – 5 – 9

Cost (IV, 10) = min {cost (III, 5) + cost (5, 10),
Cost (III, 6) + cost (6, 10),
Cost (III, 7) + cost (7, 10}
= min {20 + 30, 30 + 30, 40 + 30}
= 50 $\rightarrow$ Via the path 1 – 2 – 5 – 10

Cost (IV, 11) = min {cost (III, 5) + cost (5, 11)
Cost (III, 6) + cost (6, 11),
Cost (III, 7) + cost (7, 11)}
= min $\{20 + 40, 30 + \infty, 40 + 20\}$
= 60 $\rightarrow$ Via the path 1 – 2 – 5 – 11
or Via the path 1 – 2 – 7 – 11

Step V:

Cost (V, 12) = min {cost (IV, 8) + cost (8, 12)
Cost (IV, 9) + cost (9, 12),
Cost (IV, 10) + cost (10, 12),
Cost (IV, 11) + cost (11, 12)}
= min $\{30 + 10, 40 + \infty, 50 + \infty, 60 + \infty\}$
= 40 $\rightarrow$ Via the path 1 − 2 − 5 – 8 – 12

Cost (V, 13) = min {cost (IV, 8) + cost (8, 13)
Cost (IV, 9) + cost (9, 13),
Cost (IV, 10) + cost (10, 13),
Cost (IV, 11) + cost (11, 13)}
= min {30 + 20, 40 + 20, 50 + 10, 60 + 10}
= 50 $\rightarrow$ Via the path 1 – 2 – 5 – 8 – 13

Cost (V, 14) = min {cost (IV, 8) + cost (8, 14)
Cost (IV, 9) + cost (9, 14),
Cost (IV, 10) + cost (10, 14),
Cost (IV, 11) + cost (11, 14)}
= min {30 + 30, 40 + 10, 50 + 20, 60 + 30}
50 $\rightarrow$ Via the path 1 – 2 – 5 – 9 – 14

Step VI:

Cost (VI, 15) = min {cost (V, 12) + cost (12, 15),
Cost (V, 13) + cost (13, 15),
Cost (V, 14) + cost (14, 15)}
= min {40 + 20, 50 + 10, 50 + 30}
= 60 → Via the path 1 – 2 – 5 – 8 – 13 – 15
(or) 1 – 2 – 5 – 8 – 12 – 15

All Pairs Shortest Path Problem (Floyd–Warshall Algorithm)

A weighted graph is a collection of points (vertices) connected by lines (edges), where each edge has a weight (some real number) associated with it.

Example: A graph in the real world is a road map. Each location is a vertex and each road connecting locations is an edge. We can think of the distance travelled on a road from one location to another as the weight of that edge.

- The Floyd–Warshall algorithm determines the shortest path between all pairs of vertices in a graph.
- The vertices in a graph be numbered from 1 to n. Consider the subset {1, 2, … K} of these n vertices.
- Finding the shortest path from vertex i to vertex j that uses vertex in the set {1, 2, … K} only. There are two situations.
  1. K is an intermediate vertex on the shortest path.
  2. K is not an intermediate vertex on the shortest path.

In the first situation, we can break down our shortest path into two paths: i to K and then K to j. Note that all the vertices from i to K are from the set {1, 2, … K – 1} and that all the intermediate vertices from K to j are from the set {1, 2, … K –1}. Also in the second situation, we simply have that all intermediate vertices are from the set {1, 2, ... K – 1}. Now define the function D for a weighted graph with the vertices {1, 2, … n} as follows.

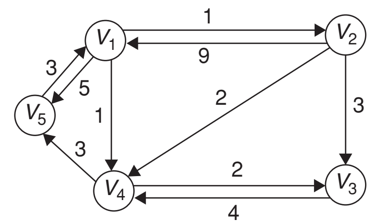
$D(i, j, K)$ = the shortest distance from vertex i to vertex j using the intermediate vertices. In the set {1, 2, … K}

Using the above idea, we can recursively define the function D.

$$D(i, j, K) = W(i, j) \text{ if } K = 0$$
$$\min (D(i, j, K-1), D(i, K, K-1) + D(K, j, K-1)) \text{ if } K > 0$$

- The first line says that if we do not allow intermediate vertices, then the shortest path between two vertices is the weight of the edge that connects them. If no such weightexists, we usually define this shortest path to be of length infinity.
- The second line pertains to allowing intermediate vertices. It says that the minimum path from i to j through vertices {1, 2, … K} is either the minimum path from i to j through vertices {1, 2, … K – 1} OR the sum of the minimum path from vertex i to K through {1, 2, … K – 1} plus the minimum path from vertex K to j through {1, 2, … K – 1}. Since this is the case, we compute both and choose the smaller of these.

Example:



The weight matrix will be

	1	2	3	4	5
1	0	1	∞	1	5
2	9	0	3	2	∞
3	∞	∞	0	4	∞
4	∞	∞	2	0	3
5	3	∞	∞	∞	0

Let $D^{(K)}[i, j]$ = weight of a shortest path from v_i to v_j using only vertices from $\{v_1, v_2, \ldots v_k\}$ as intermediate vertices in the path.

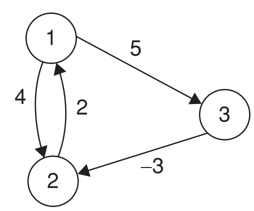
- $D^{(0)} = W$
- $D^{(n)} = D$ which is the goal matrix.

How to compute $D^{(K)}$ from $D^{(K-1)}$?

Case I: A shortest path from v_i to v_j restricted to using only vertices from $\{v_1, v_2, \ldots v_K\}$ as intermediate vertices does not use V_K.
Then $D^{(K)}[i, j] = D^{(K-1)}[i, j]$

Case II: A shortest path from v_i to v_j restricted to using only vertices from $\{v_1, v_2 \ldots v_K\}$ as intermediate vertices does use V_K. Then $D^{(K)}[i, j] = D^{(K-1)}[i, K] + D^{(K-1)}[K, j]$
Since $D^{(K)}[i, j] = D^{(K-1)}[i, j]$
or $D^{(K)}[i, j] = D^{(K-1)}[i, K] + D^{(K-1)}[K, j]$
We conclude: $D^{(K)}[i, j] = \min\{D^{(K-1)}[i, j], D^{(K-1)}[i, K] + D^{(K-1)}[K, j]\}$

Example: 1



$W = D^{\circ} =$

	1	2	3

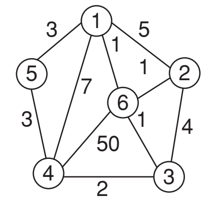
Example 2:



The final distance matrix and P

$D^6 =$

	1	2	3	4	5	6
1	0	2(6)	2(6)	4(6)	3	1
2	2(6)	0	2(6)	4(6)	5(6)	1
3	2(6)	2(6)	0	2	5(4)	1
4	4(6)	4(6)	2	0	3	3(3)
5	3	5(4)	5(4)	3	0	4(1)
6	1	1	1	3(3)	4(1)	0

The values in parenthesis are the non-zero P values.

Table 1 *Divide and conquer vs dynamic programming.*

1. This design strategy divides the problem into sub problems, conquer the each sub problem recursively, finally combine all the sub problem solutions, for the original problem.	1. This design strategy chooses an optimal solution for the problem, by recursively defining the value of optimal solution, these values are computed in bottom up fashion or top down fashion.
2. each sub problem is solved recursively, and consumes more time at each sub problem	2. Each sub problem is solved only once and is stored in table
3. Sub problems are independent of each other e.g., Binary search	3. The sub problems are dependent e.g., Traveling sales person problem

Dynamic Programming vs Greedy Method

The main difference between greedy method (*GM*) and dynamic programming (*DP*) methodology is, *DP* considers all possible solutions for the given problem and picks the optimal one. Where as greedy, considers only one set of solutions to the problem.

The other difference between *GM* and *DP* is that, *GM* considers the choice, which is best at that step, which is done at each level of the sub problem. That is, it won't reconsider its choice. The choices reflect only present, won't consider the future choices, where as *DP* tries out all the best alternatives and finds the optimal solution. It implements principle of optimality. At each stage of the problem, it decides based on the previous decision made in the previous stage.

Hashing Methods

Uniform Hash Function

If the keys, K, are integers randomly distributed in [0, r] then hash function $H(K)$ is given as

$$H(K) = \left\lfloor \frac{mk}{r} \right\rfloor$$

$H(K)$ is a uniform hash function

Uniform hashing function should ensure

$$\sum_{K|h(K)=0} P(K) = \sum_{K|h(K)=1} P(K) = \cdots \sum_{K|h(K)=0} P(K) = \frac{1}{m}$$

$P(K)$ = probability that a key K, occurs that is the number of keys that map to each slot is equal.

Division method

Hashing an integer x is to divide x by M and then to use the remainder modulo M. This is called the division method of hashing. In this case the hash function is

$$\boxed{h(x) = x \bmod M}$$

Generally this approach is quite good for just about any value of M. However, in certain situations some extra care is needed in the selection of a suitable value for M. For example, it is often convenient to make M an even number. But this means that $h(x)$ is even if x is even, and $h(x)$ is odd of x is odd. If all possible keys are equiprobable, then this is not a problem. However, if say even keys are more likely than odd keys, the function $h(x) = x \bmod M$ will not spread the hashed values of those keys evenly.

- Let M be a power of two, i.e., $M = 2^k$ for some integer $k > 1$. In this case, the hash function $h(x) = x \bmod 2^k$ simply extracts the bottom k-bits of the binary representation of x. While this hash function is quite easy to compute, it is not a desirable function because it does not depend on all the bits in the binary representation of x.
- For these reasons M is often chosen to be a prime number. Suppose there is bias in the way the keys are created that makes it more likely for a key to be a multiple of some small constant, say two or three. Then making M a prime increases the likelihood that those keys are spread out evenly. Also if M is a prime number, the division of x by that prime number depends on all the bits of x, not just the bottom k-bits, for some small constant k.

Example: Hash table size = 10

Key value = 112

Hash function = $h(k) = k \bmod M$

$= 112 \bmod 10 = 2$

Disadvantage: A potential disadvantage of the division method is due to the property that consecutive keys map to consecutive hash values.

$h(i) = i$

$h(i + 1) = i + 1 \pmod M$

$h(i + 2) = i + 2 \pmod M$

.

.

.

While this ensures that consecutive keys do not collide, it does not mean that consecutive array locations will be occupied. We will see that in certain implementations this can lead to degradation in performance.

Multiplication method

A variation on the middle-square method that alleviates its deficiencies is called, multiplication hashing method. Instead of multiplying the key x by itself, we multiply the key by a carefully chosen constant 'a' and then extract the middle k bits from the result. In this case, the hashing function is

$$\boxed{h(x) = \left\lfloor \frac{M}{W}(ax \bmod W) \right\rfloor}$$

if we want to avoid the problems that the middle-square method encounters with keys having a large number of leading (or) trailing zero's then we should choose an 'a' that has neither leading nor trailing zero's.

Furthermore, if we, choose an 'a' that is relatively prime to W, then there exists another number 'a' such that $aa' = 1 \pmod W$. Such a number has the nice property that if we take a key x, and multiply it by 'a' to get ax, we can recover the original key by multiplying the product again by a', since $a \times a' = aa'x = 1x$.

The multiplication method for creating a hash function operates in two steps:

Step 1: Multiply the key K by a constant A in the range $0 < A < 1$ and extract the fractional part of KA.

Step 2: Multiply this value by M and take the floor of the result.

In short the hash function is

$$h(k) = \lfloor M \cdot (KA \bmod 1) \rfloor$$

Where (KA mod 1) denotes the fractional part of KA, that is $KA \quad \lfloor KA \rfloor$

Example:

Let $m = 10000$, $K = 123456$ and $A = \frac{\sqrt{5}-1}{2}$

$= 0.618033$

Then $h(k) = \lfloor 10000 \cdot (123456 \cdot 0.61803 \bmod 1) \rfloor$

$= \lfloor 10000 \cdot (76300.00412 \bmod 1) \rfloor$

$= \lfloor 10000 \cdot 0.00412 \rfloor = 41$

Practical issues

- Easy to implement
  –On most machines multiplication is faster than division.
  –We can substitute one multiplication by shift operation.
  –We don't need to do floating-point operations.
- If successive keys have a large interval, $A = 0.6125423371$ can be recommended.

Mid-square method

A good hash function to use with integer key values is the mid-square method. The mid-square method squares the key value, and then takes out the middle 'r' bits of the result, giving a value in the range 0 to $2^r - 1$. This works well because most (or) all bits of the key value contribute to the result.

Example:
Consider records whose keys are 4-digit numbers in base 10. The goal is to hash these key values to a table of size 100(i.e., *a* range of 0 to 99).

This range is equivalent to two digits in base 10.

That is $r = 2$. If the input is the number 4567, squaring yields an 8-digit number, 20857489. The middle two digits of this result are 57. All digits of the original key value (equivalently, all bits when the number is viewed in binary) contribute to the middle two digits of the squared value. Thus, the result is not dominated by the distribution of the bottom or the top digit of the original key value. Of course, if the key values all tend to be small numbers, then their squares will only affect the low order digits of the hash value.

Example: To map the key 3121 into a hash table of size 1000, we square it $(3121)^2 = 97\underline{406}41$ and extract 406 as the hash value.

Folding method

The folding method breaks up a key into precise segments that are added to form a hash value, and still another technique is to apply a multiplicative hash function to each segment individually before folding.

Algorithm $H(x) = (a + b + c) \bmod m$. Where a, b, and c represent the preconditioned key broken down into three parts, m is the table size, and mod stands for modulo. In other words: The sum of three parts of the pre conditioned key is divided by the table size. The remainder is the hash key.

Example:
Fold the key 123456789 into a hash table of ten spaces (0 through 9)

We are given $x = 123456789$ and the table size (i.e., $m = 10$)

Since we can break x into three parts any way, we will break it up evenly.

Thus $a = 123$, $b = 456$ and $c = 789$

$H(x) = (a + b + c) \bmod M$

$H(123456789) = (123 + 456 + 789) \bmod 10$

$= 1368 \bmod 10 = 8$

123456789 are inserted into the table at address 8.

The folding method is distribution independent.

Resolving collisions In collision resolution strategy algorithms and data structures are used to handle two hash keys that hash to the same hash keys. There are a number of collision resolution techniques, but the most popular are open addressing and chaining.

- Chaining: An array of linked list, Separate chaining
- Open Addressing: Array based implementation:
  – Linear probing (Linear Search)
  – Quadratic probing (non-linear search)
  – Double hashing (use two hash functions)

Separate chaining Every linked list has each element that collides to the similar slot. Insertion need to locate the accurate slot and appending to any end of the list in that slot wherever, deletion needs searching the list and removal.

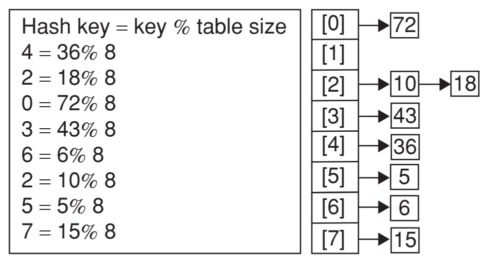


Figure 1 Separate chaining

Open addressing Open addressing hash tables are used to stock up the records straight inside the array. This approach is also known as closed hashing. This procedure is based on probing. Well known probe sequence include:

- Linear probing: In which the interval between probes is fixed often at 1.
- Quadratic probing: In which the interval between probes increases proportional to the hash value (the interval thus increasing linearly and the indices are described by a quadratic function).
- Double hashing: In which the interval between probes is computed by another hash function.

(i) **Linear probing:** Linear probing method is used for resolving hash collisions of values of hash functions by sequentially searching the hash table for a free location. The item will be stored in the next available slot in the table in linear probing. Also an assumption is made that the table is not already full.

This is implemented via a linear search for an empty slot, from the point of collision.

If the physical end of table is reached during the linear search, the search will again get start around to the beginning of the table and continue from there. The table is considered as full, if an empty slot is not found before reaching the point of collision.

[5]	10
[6]	6
[7]	7

Figure 2 Linear probing

Limitation: A problem with linear probe method is primary clustering. In primary clustering blocks of data may possibly be able to form collision. Several attempts may be required by any key that hashes into the cluster to resolve the collision.

(ii) Quadratic probing: To resolve the primary clustering problem, quadratic probing can be used. With quadratic probing, rather than always moving one spot, move i^2 spots from the point of collision where i is the number of attempts needed to resolve the collision.

[0]	49
[1]	
[2]	58
[3]	69
[4]	
[5]	
[6]	
[7]	
[8]	18
[9]	89

89% 10 = 9
18% 10 = 8
49% 10 = 9 → 1 attempt needed → 1^2 = 1 spot
58% 10 = 8 → 2 attempts needed → 2^2 = 4 spot
69% 10 = 9 → 2 attempts needed → 2^2 = 4 spot

Limitation: Maximum half of the table can be used as substitute locations to resolve collisions. Once the table gets more than half full, its really hard to locate an unfilled spot. This new difficulty is recognized as secondary clustering because elements that hash to the same hash key will always probe the identical substitute cells.

(iii) Double hashing: Double hashing uses the idea of applying a second hash function to the key when a collision occurs, the result of the second hash function will be the number of positions from the point of collision to insert. There are some requirements for the second function:

1. It must never evaluate to zero
2. Must make sure that all cells can be probed.

A popular second hash function is:
Hash(key) = R-(Key mod R) where R is a prime number smaller than the size of the table.

Table size = 10 elements
Hash1(key) = key %10
Hash 2(key) = 7 – (key %7)
Insert keys: 89, 18, 49, 58 and 69
Hash key (89) = 89% 10 = 9
Hash key (18) = 18% 10 = 8
Hash key (49) = 49% 10 = 9 (collision)
= (7 – (49% 7)
= (7 – (0))
= 7 positions from [9]

Matrix-chain Multiplication

We are given a sequence of n matrices $m_1, m_2 \dots m_n$ to be multiplied. If the chain matrices is $< m_1, m_2, m_3, m_4>$, the product m_1, m_2, m_3, m_4 can be fully parenthesized in 5 distinct ways:

1. $(m_1 (m_2 (m_3 m_4)))$
2. $(m_1 ((m_2 m_3) m_4))$
3. $((m_1 m_2) (m_3 m_4))$
4. $((m_1 (m_2 m_3)) m_4)$
5. $(((m_1 m_2) m_3) m_4)$

The way we parenthesize a chain of matrices can have a dramatic impact on the cost of evaluating the product. We can multiply 2 matrices A and B only if they are compatible i.e., the number of columns of A must equal the number of rows of B. If A is a $(p \times q)$ matrix and B is a $(q \times r)$ matrix, the resulting matrix C is a $(p \times r)$ matrix. The time to compute C is the number of scalar multiplications, which is (pqr).

Example: Consider the problem of a chain $<m_1, m_2, m_3>$ of three matrices. Suppose that the dimensions of the matrices are (6 × 8), (8 × 14), (14 × 20) respectively. Which parenthesization will give least number of multiplications?

Soluation:

(i) $((m_1\, m_2)\, m_3)$

$[m_1]_{6\times 8} \times [m_2]_{8\times 14} = [m_1\, m_2]_{6\times 14}$

Number of multiplications performed

$= 6 \times 8 \times 14 = 672$

$[m_1\, m_2]_{6\times 14} \times [m_3]_{14\times 20} = ((m_1\, m_2)\, m_3)_{6\times 20}$

Number of multiplications performed

$= 6 \times 14 \times 20 = 1680$

Total number of multiplications

$= 672 + 1680 = 2352$

(ii) $(m_1\, (m_2\, m_3))$

$[m_2]_{8\times 14} \times [m_3]_{14\times 20} = [m_2\, m_3]_{8\times 20}$

Number of multiplications performed

$= 8 \times 14 \times 20 = 2240$

$[m_1]_{6\times 8} \times [m_2\, m_3]_{8\times 20} = (m_1\, (m_2\, m_3))_{6\times 20}$

Number of multiplications performed

$= 6 \times 8 \times 20 = 960$

Total number of multiplications $= 960 + 2240 = 3200$

$\therefore$ $((m_1\, m_2)\, m_3)$ gives least number of multiplications.

We need to define the cost of an optimal solution recursively in terms of the optimal solutions to sub problems. For Matrix-chain multiplication problem, we pick as our sub problem the problems of determining the minimum cost of a parenthesization of $A_i\, A_{i+1} \ldots A_j$ for $1 \le i \le j \le n$ let $m[i, j]$ be the minimum number of scalar multiplications needed to compute the matrix $A_{i} \ldots_{j}$; for the full problem, the cost of a cheapest way to compute $A_{1} \ldots_{N}$ would be $m[1, n]$. We can define $m[i, j]$ recursively as follows:

$$\boxed{m\,[i, j] = m\,[i, k] + m\,[k + 1, j] + P_{i-1}\, P_k\, P_j}$$

If $i = j$, the problem is trivial. The chain consists of just one matrix $A_{i} \ldots_{i} = A_i$, so that no scalar multiplications are necessary to compute the product.

Minimum cost of parenthesizing the product $A_i\, A_{i+1} \ldots A_j$ becomes

$$m[i, j] = \begin{cases} 0 \quad if\ i = j \\ \min\{m[i,k] + m[k+1, j] \\ +\ p_{i-1} p_k p_i\} \quad if\ i < j, i \le k < j \end{cases}$$

The $m[i, j]$ values give the costs of optimal solutions to sub problems.

At this point, to write a recursive algorithm based on recurrence to compute the minimum cost $m[1, n]$ for multiplying $A_1\, A_2 \ldots A_n$. However, this algorithm takes exponential time, which is not better than the brute force method of checking each way of parenthesizing the product. The important observation we can make at this point is that we have relatively few sub problems, one problem for each choice of i and j satisfying $1 \le i \le j \le n$ (or) $\binom{n}{2} + n = \theta(n^2)$ in all. The property of overlapping sub problems is the second hallmark of the applicability of dynamic programming.

The first hall mark being optimal substructure.

Algorithm

```
n ← length [p] – 1
for i ← 1 to n
do m[i, i] ← 0
for i ← 2 to n
do for i ← 1 to n – i + 1
do j ← i + i – 1
m[i, j] ← ∞
for k ← i to j – 1
do q ← m [i, k] + m [k + 1, j] + P_(i – 1) P_k P_j
if q < m [i, j]
then m [i, j] ← q
S[i, j] ← k
return m and S
```

It first computes $m[i, j] \leftarrow 0$ for $i = 1, 2 \ldots n$ (the minimum costs for chains of length 1). To compute $m[i, i + 1]$ for $i = 1, 2, \ldots n - 1$(the minimum costs for chains of length $\lambda = 2$ and so on). At each step, the $m[i, j]$ cost computed depends only on table entries $m[i, k]$ and $m[k + 1, j]$ already computed. An entry $m[i, j]$ is computed using the products $P_{i-1}\, P_k\, P_j$ for $k = i, i + 1, \ldots j - 1$. A simple inspection of the nested loop structure of the above algorithm yields a running time of $O(n^3)$ for the algorithm.

Longest Common Subsequence

A sub sequence of a given sequence is just the given sequence with 0 or more elements left out. Formally, given a sequence $x = <x_1, x_2 \cdots x_m>$, another sequence $z = <z_1, z_2 \cdots z_k>$ is a subsequence of x if there exists a strictly increasing sequence $<i_1, i_2 \ldots i_k>$ of indices of x such that for all $j = 1, 2 \cdots k$, we have $x_{ij} = z_j$

Example: $z = < B, C, D, B >$ is a subsequence of $x = <A, B, C, B, D, A, B>$ with corresponding index sequence <2, 3, 5, 7>

Example: Given 2 sequences x and y, we say that a sequence z is a common sub sequence of x and y if z is a sub sequence of both x and y.

If $x = <A, B, C, B, D, A, B>$

$y = <B, D, C, A, B, A>$

The sequence $<B, C, A>$ is a common subsequence of both x and y.

The sequence $<B, C, A>$ is not a longest common subsequence (LCS) of x and y since it has length '3' and the sequence $<B, C, B, A>$, which is also common to both x and y, has length 4. The sequence $<B, C, B, A>$ is an LCS of x and y, as is the sequence $<B, D, A, B>$, since there is no common subsequence of length 5 or greater.

- In the longest-common-sub sequence problem, we are given 2 sequences $x = <x_1, x_2, x_3 \ldots x_m>$ and $y = <y_1, y_2 \ldots y_n>$ and wish to find a maximum length common subsequence of x and y.
- LCS problem can be solved efficiently using dynamic programming.
- A brute force approach to solve the LCS problem is to enumerate all subsequences of x and check each subsequence to see if it is also a subsequence of y, keeping track of the longest subsequence found. Each subsequence of x corresponds to a subset of the indices $\{1, 2 \ldots m\}$ of x. There are 2^m subsequences of x, so this approach requires exponential time, making it impractical for long sequences.
- The classes of sub problems correspond to pairs of 'pre fixes' of 2 input sequences:

Given a sequence $x = <x_1, x_2 \cdots x_m>$, we define the ith prefix of x, for $i = 0, 1, \ldots m$, as

$$x_i = <x_1\, x_2 \ldots x_i>$$

Example: If $x = <A, B, C, B, D, A, D>$, then $x_4 = <A, B, C, B>$ and x_0 is the empty sequence. LCS problem has an optimal sub-structure property.

Optimal Substructure of LCS

Let $x = <x_1, x_2 \ldots x_m>$ and $y = <y_1, y_2 \ldots y_n>$ be sequences and let $z = <z_1, z_2 \ldots z_k>$ be any LCS of x and y then

1. If $x_m = y_n$, then $z_k = x_m = y_n$ and z_{k-1} is an LCS of x_{m-1} and y_{n-1}.
2. If $x_m \neq y_n$, then $z_k \neq x_m$ implies that z is an LCS of x_{m-1} and y.
3. If $x_m \neq y_n$, then $z_k \neq y_n$ implies that z is an LCS of x and y_{n-1}.

NP-HARD AND *NP*-COMPLETE

A mathematical problem for which, even in theory, no shortcut or smart algorithm is possible that would lead to a simple or rapid solution. Instead the only way to find an optimal solution is a computationally intensive, exhaustive analysis in which all possible outcomes are tested. Examples of NP-hard problems include the travelling salesman problem.

P-problem

A problem is assigned to the *P*(polynomial time) class if there exists at least one algorithm to solve that problem, such that number of steps of the algorithm is bounded by a polynomial in n, where n is the length of the input.

NP-problem

A problem is assigned to the *NP* (non-deterministic polynomial time) class if it is solvable in polynomial time by a non-deterministic turing machine.

A *P*-problem (whose solution time is bounded by a polynomial) is always also *NP*. If a problem is known to be *NP*, and a solution to the problem is somehow known, then demonstrating the correctness of the solution can always be reduced to a single *P* (polynomial time) verification. If *P* and *NP* are not equivalent then the solution of *NP*-problems requires (in the worst case) an exhaustive search.

A problem is said to be *NP*-hard, if an algorithm for solving it can be translated into one for solving any other *NP*-problem. It is much easier to show that a problem is *NP* than to show that it is *NP*-hard. A problem which is both *NP* and *NP*-hard is called an *NP*-complete problem.

P versus NP-problems

The *P* versus *NP* problem is the determination of whether all *NP*-problems are actually *P*-problems, if *P* and *NP* are not equivalent then the solution of *NP*-problem requires an exhaustive search, while if they are, then asymptotically faster algorithms may exist.

NP-complete problem

A problem which is both *NP* (verifiable in non-deterministic polynomial time) and *NP*-hard (any *NP*-problem can be translated into this problem). Examples of *NP*-hard problems include the Hamiltonian cycle and travelling sales man problems.

Example:

Circuit satisfiability is a good example of problem that we don't know how to solve in polynomial time. In this problem, the input is a Boolean circuit. A collection of and, or and not gates connected by wires. The input to the circuit is a set of m Boolean (true/false) values $x_1 \ldots x_m$. The output is a single Boolean value. The circuit satisfiability problem asks, given a circuit, whether there is an input that makes the circuit output TRUE, or conversely, whether the circuit always outputs FLASE. Nobody knows how to solve this problem faster than just trying all 2^m possible inputs to the circuit but this requires exponential time.

P, NP, and Co-NP

- *P* is a set of yes/no problems that can be solved in polynomial time. Intuitively *P* is the set of problems that can be solved quickly.
- *NP* is the set of yes/no problems with the following property: If the answer is yes, then there is a proof of this fact that can be checked in polynomial time. Intuitively *NP* is the set of problems where we can verify a YES answer quickly if we have the solution in front of us.

Example: The circuit satisfiability problem is in *NP*.

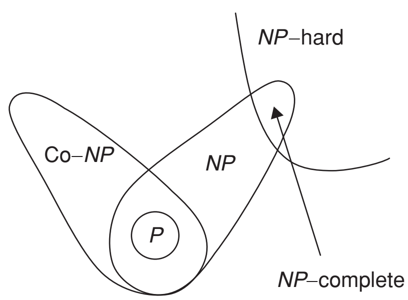
If the answer is yes, then any set of m input values that produces TRUE output is a proof of this fact, we can check the proof by evaluating the circuit in polynomial time.

- Co-*NP* is the exact opposite of *NP*. If the answer to a problem in co-*NP* is no, then there is a proof of this fact that can be checked in polynomial time.

- π is *NP*-hard $\Rightarrow$ if π can be solved in polynomial time, then $P = NP$.

This is like saying that if we could solve one particular *NP*-hard problem quickly, then we could solve any problem whose solution is easy to understand, using the solution to that one special problem as a subroutine. *NP*-hard problems are atleast as hard as any problem in *NP*.

- Saying that a problem is *NP*-hard is like saying 'If I own a dog, then it can speak fluent English'. You probably don't know whether or not I own a dog, but you're probably pretty sure that I don't own a talking dog. Nobody has a mathematical proof that dogs can't speak English. The fact that no one has ever heard a dog speak English is evidence as per the hundreds of examinations of dogs that lacked the proper mouth shape and brain power, but mere evidence is not a proof nevertheless, no sane person would believe me if I said I owned a dog that spoke fluent English. So the statement 'If I own a dog then it can speak fluent English' has a natural corollary: No one in their right mind should believe that I own a dog ! Likewise if a problem is *NP*-hard no one in their right mind should believe it can be solved in polynomial time.



Cooks Theorem

Cook's theorem states that CNFSAT is *NP*-Complete

It means, if the problem is in *NP*, then the deterministic Turing machine can reduce the problem in polynomial time.

The inference that can be taken from these theorems is, if deterministic polynomial time algorithm exists for solving satisfiability, then to all problems present in *NP* can be solved in polynomial time.

Non-deterministic Search

Non-deterministic algorithms are faster, compared to deterministic ones. The computations are fast as it always chooses right step

The following functions are used to specify these algorithms

1. Choice (A), which chooses a random element from set A
2. Failure (A), specifies failure
3. Success ( ), Specifies success

The non-deterministic search is done as follows.

Let us consider an array $S[1 \ldots n]$, $n \geq 1$ we need to get the indice of 'i' such that $S[i] = t$ (or) $i = 0$. The algorithm is given below.

Steps:

1. i = Choice $(1, n)$;
2. if $S[i] = t$, then
   (i) Print (i);
   (ii) Success ( );
3. Print (0)
   failure
4. Stop.

If the search is successful it returns the indice of array '*S*', otherwise it returns '0', the time complexity is $\Omega(n)$.

Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Hash the keys 12, 44, 13, 88, 23, 94, 11, 39, 20 using the hash function with chaining $(2k + 5) \bmod 11$, which of the following slots are empty?
(A) 0, 1, 2, 3, 4 (B) 0, 2, 3, 4, 8, 10
(C) 0, 1, 2, 4, 8, 10 (D) 0, 1, 2, 4, 8

2. Using linear probing on the list given in the above question with the same hash function, which slots are not occupied?
(A) 3, 4 (B) 4, 5
(C) 3, 6 (D) 4, 6

3. In hashing, key value 123456 is hashed to which address using multiplication method ($m = 10^4$)?
(A) 40 (B) 41
(C) 42 (D) 44

4. Insert element 14 into the given hash table with double hashing? $h_1(k) = k \bmod 13$, $h_2(k) = 1 + (k \bmod 11)$. The element will occupy, which slot?

5. Consider the below given keys:

257145368, 25842354, 12487654, 248645452. Find the hash values of keys using shift folding method?

(A) 770, 221, 153, 345 (B) 221, 770, 153, 345
(C) 760, 770, 153, 345 (D) 815, 770, 153, 345

6. Consider the following two problems on unidirected graphs.

β : Given $G(V, E)$, does G have an independent set of size $|V|-4$?

α : Given $G(V, E)$, does G have an independent set of size 5?

Which of the following is true?

(A) β is in P and α is in NP-Complete
(B) β is in NP-Complete and α is in P
(C) Both α and β are NP-Complete
(D) Both α and β are in P

7. Let S be an NP-complete problem and Q and R be two other problems not known to be in NP. Q is polynomial-time reducible to S and S is polynomial-time reducible to R. Which one of the following statements is true?

(A) R is NP-Complete (B) R is NP-Hard
(C) Q is NP-Complete (D) Q is NP-Hard

8. Let FHAM_3 be the problem of finding a Hamiltonian cycle in a graph $G = (V, E)$ with $|V|$ divisible by 3 and DHAM_3 be the problem of determining if a Hamiltonian cycle exists in such graphs. Which of the following is true?

(A) Both FHAM_3 and DHAM_3 are NP-hard
(B) FHAM_3 is NP-hard but DHAM_3 is not
(C) DHAM_3 is NP-hard but FHAM_3 is not
(D) Neither FHAM_3 nor DHAM_3 is NP-hard

9. Consider a hash table of size 7, with starting index '0' and a hash function $(3x + 4) \bmod 7$. Initially hash table is empty. The sequence 1, 3, 8, 10 is inserted into the table using closed hashing then what is the position of element 10?

(A) 1st (B) 2nd
(C) 6th (D) 0th

10. Place the given keys in the hash table of size 13, index from '0' by using open hashing, hash function is $h(k)$ mod 13.

Keys: A, FOOL, HIS, AND

(hint : Add the positions of a word's letters in the alphabet, take $A \to 1$, $B \to 2$, $C \to 3$. $D \to 4$ … $Z \to 26$).

Which of the following shows the correct hash addresses of keys?

(A) A – 1, FOOL – 10, HIS – 9, AND – 6
(B) A – 1, FOOL – 9, HIS – 10, AND – 6
(C) A – 0, FOOL – 6, HIS – 10, AND – 9
(D) A – 0, FOOL – 9, HIS – 9, AND – 6

11. Consider the following input (322, 334, 471, 679, 989, 171, 173, 199) and the hash function is x mod 10 which statement is true?

I. 679, 989, 199 hash to the same value
II. 471, 171, hash to the same value
III. Each element hashes to a different value
IV. All the elements hash to the same value

(A) I Only (B) II Only
(C) I and II (D) III

12. For the input 30, 20, 56, 75, 31, 19 and hash function $h(k) = k$ mod 11, what is the largest number of key comparisons in a successful search in the open hash table.

(A) 4 (B) 3
(C) 5 (D) 2

13. The keys 12, 18, 13, 2, 3, 23, 5 and 15 are inserted into an empty hash table of length 10 using open addressing with hash function, $h(k) = k$ mod 10 and linear probing.

15	9

14. Which one of the following is correct?

(A) Finding shortest path in a graph is solvable in poly-nomial time.
(B) Finding longest path from a graph is solvable in poly-nomial time.
(C) Finding longest path from a graph is solvable in polynomial time, if edge weights are very small values.
(D) Both (A) and (B) are correct

15. In the following pair of problems

$$\underset{\text{I}}{\underline{\text{2 CNF Satisfiability}}} \text{ Vs } \underset{\text{II}}{\underline{\text{3 CNF Satisfiability}}}.$$

(A) I is solvable in polynomial time, II is NP complete problem.
(B) II is solvable in polynomial time, I is NP complete problem.
(C) Both are solvable in polynomial time
(D) None can be solved in polynomial time.

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. For *NP*-complete problems
(A) Several polynomial time algorithms are available
(B) No polynomial time algorithm is discovered yet
(C) Polynomial time algorithms exist but not discovered
(D) Polynomial time algorithms will not exist, hence cannot be discovered

2. In the division method for creating hash functions, we map a key k into one of m slots by taking the remainder of k divided by m. That is, the hash function is
(A) $h(k) = m \bmod k$ (B) $h(k) = m \bmod m/k$
(C) $h(k) = k \bmod m$ (D) $h(k) = mk \bmod k$

3. In the division method for creating hash function, which of the following hash table size is most appropriate?
(A) 2 (B) 7
(C) 4 (D) 8

4. Which of the following techniques are commonly used to compute the probe sequence required for open addressing?
(A) Linear probing (B) Quadratic probing
(C) Double hashing (D) All the above

5. Which of the following problems is not *NP*-hard?
(A) Hamiltonian circuit problem
(B) The 0/1 knapsack problem
(C) The graph coloring problem
(D) None of these

6. For problems x and y, y is *NP*-complete and x reduces to y in polynomial time. Which of the following is true?
(A) If x can be solved in polynomial time, then so can y
(B) x is *NP*-hard
(C) x is *NP*-complete
(D) x is in *NP*, but not necessarily *NP*-complete

7. If P_1 is *NP*-complete and there is a polynomial time reduction of P_1 to $P_{2,}$ then P_2 is
(A) NP-complete
(B) Not necessarily NP-complete
(C) Cannot be *NP*-complete
(D) None of these

8. A problem is in *NP*, and as hard as any problem in *NP*. The given problem is
(A) *NP* hard
(B) *NP* complete
(C) *NP*
(D) *NP*-hard $\cap$ *NP*-complete

9. Which of the following is TRUE?
(A) All *NP*-complete problems are *NP*-hard.
(B) If an *NP*-hard problem can be solved in polynomial time, then all *NP*-complete problems can be solved in polynomial time.
(C) *NP*-hard problems are not known to be *NP*-complete.
(D) All the above

10. If a polynomial time algorithm makes polynomial number of calls to polynomial time subroutines, then the resulting algorithm runs in
(A) Polynomial time (B) No-polynomial time
(C) Exponential time (D) None of these

11. If a polynomial time algorithm makes atmost constant number of calls to polynomial time subroutines, then the resulting algorithm runs in
(A) Polynomial time (B) No-polynomial time
(C) Exponential time (D) None of these

12. When a record to be inserted maps to an already occupied slot is called
(A) Hazard
(B) Collision
(C) Hashing
(D) Chaining

13. Worst-case analysis of hashing occurs when
(A) All the keys are distributed
(B) Every key hash to the same slot
(C) Key values with even number, hashes to slots with even number
(D) Key values with odd number hashes to slots with odd number

14. Main difference between open hashing and closed hashing is
(A) Closed hashing uses linked lists and open hashing does not.
(B) Open hashing uses linked list and closed hashing does not
(C) Open hashing uses tree data structure and closed uses linked list
(D) None of the above

15. The worst case scenario in hashing occurs when
(A) All keys are hashed to the same cell of the hash table
(B) The size of hash table is bigger than the number of keys
(C) The size of hash table is smaller than the number of keys
(D) None of the above

Previous Years' Questions

1. Consider a hash table of size seven, with starting index zero, and a hash function $(3x + 4)$ mod7. Assuming the hash table is initially empty, which of the following is the contents of the table when the sequence 1, 3, 8, 10 is inserted into the table using closed hashing? Note that − denotes an empty location in the table. **[2007]**

   (A) 8, −, −, −, −, −, 10 (B) 1, 8, 10, −, −, −, 3
   (C) 1, −, −, −, −, −, 3 (D) 1, 10, 8, −, −, −, 3

Common data for questions 2 and 3: Suppose the letters a, b, c, d, e, f have probabilities $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}, \frac{1}{32}, \frac{1}{32}$, respectively.

2. Which of the following is the Huffman code for the letter a, b, c, d, e, f? **[2007]**
   (A) 0, 10, 110, 1110, 11110, 11111
   (B) 11, 10, 011, 010, 001, 000
   (C) 11, 10, 01, 001, 0001, 0000
   (D) 110, 100, 010, 000, 001, 111

3. What is the average length of the correct answer to above question? **[2007]**

   (A) 3 (B) 2.1875
   (C) 2.25 (D) 1.9375

4. The subset-sum problem is defined as follows: Given a set S of n positive integers and a positive integer W, determine whether there is a subset of S whose elements sum to W.

   An algorithm Q solves this problem in $O(nW)$ time. Which of the following statements is false? **[2008]**

   (A) Q solves the subset-sum problem in polynomial time when the input is encoded in unary
   (B) Q solves the subset-sum problem in polynomial time when the input is encoded in binary
   (C) The subset sum problem belongs to the class NP
   (D) The subset sum problem is NP-hard

5. Let π_A be a problem that belongs to the class NP. Then which one of the following is TRUE? **[2009]**

   (A) There is no polynomial time algorithm for π_A.
   (B) If π_A can be solved deterministically in polynomial time, then $P = NP$.
   (C) If π_A is NP-hard, then it is NP-complete.
   (D) π_A may be undecidable.

6. The keys 12, 18, 13, 2, 3, 23, 5 and 15 are inserted into an initially empty hash table of length 10 using open addressing with hash function $h(k) = k$ mod 10 and linear probing. What is the resultant hash table? **[2009]**

Common data for questions 7 and 8: A sub-sequence of a given sequence is just the given sequence with some elements (possibly none or all) left out. We are given two sequences $X[m]$ and $Y[n]$ of lengths m and n, respectively, with indexes of X and Y starting from 0.

7. We wish to find the length of the longest common sub-sequence (LCS) of $X[m]$ and $Y[n]$ as $l(m, n)$, where an incomplete recursive definition for the function $l(i, j)$ to compute the length of the LCS of $X[m]$ and $Y[n]$ is given below:
   $I(i, j) = 0$, if either $i = 0$ or $j = 0$
   = expr1, if $i, j > 0$ and $X[i - 1] = Y[j - 1]$
   = expr2, if $i, j > 0$ and $X[i - 1] \neq Y[j - 1]$

   Which one of the following options is correct? **[2009]**
   (A) expr1 $\equiv I(i - 1, j) + 1$
   (B) expr1 $\equiv I(i, j - 1)$
   (C) expr2 $\equiv \max(I(i - 1, j), I(i, j - 1))$
   (D) expr2 $\equiv \max(I(i - 1, j - 1), I(i, j))$

8. The values of $l(i, j)$ could be obtained by dynamic programming based on the correct recursive definition of $l(i, j)$ of the form given above, using an array $L[M, N]$, where $M = m + 1$ and $N = n + 1$, such that $L[i, j] = l(i, j)$.
   Which one of the following statements would be TRUE regarding the dynamic programming solution for the recursive definition of $l(i, j)$? **[2009]**
   (A) All elements of L should be initialized to 0 for the values of $l(i, j)$ to be properly computed.

(B) The values of $l(i, j)$ may be computed in a row major order or column major order of $L(M, N)$.
(C) The values of $l(i, j)$ cannot be computed in either row major order or column major order of $L(M, N)$.
(D) $L[p, q]$ needs to be computed before $L[r, s]$ if either $p < r$ or $q < s$.

9. The weight of a sequence $a_0, a_1, \cdots, a_{n-1}$ of real numbers is defined as $a_0 + a_1/2 + \cdots + a_{n-1}/2^{n-1}$. A subsequence of a sequence is obtained by deleting some elements from the sequence, keeping the order of the remaining elements the same. Let X denote the maximum possible weight of a subsequence of $a_0, a_1, \ldots, a_{n-1}$. Then X is equal to **[2010]**

(A) $\max(Y, a_0 + Y)$ (B) $\max(Y, a_0 + Y/2)$
(C) $\max(Y, a_0 + 2Y)$ (D) $a_0 + Y/2$

10. Four matrices M_1, M_2, M_3 and M_4 of dimensions $p \times q$, $q \times r$, $r \times s$ and $s \times t$ respectively, can be multiplied in several ways with different number of total scalar multiplications. For example when multiplied as $((M_1 \times M_2) \times (M_3 \times M_4))$, the total number of scalar multiplications is $pqr + rst + prt$. When multiplied $(((M_1 \times M_2) \times M_3) \times M_4)$ the total number of scalar multiplications is $pqr + prs + pst$.

If $p = 10$, $q = 100$, $r = 20$, $s = 5$ and $t = 80$, then the minimum number of scalar multiplications needed is **[2011]**

(A) 248000
(B) 44000
(C) 19000
(D) 25000

11. Assuming $P \neq NP$, which of the following is **TRUE**? **[2012]**

(A) NP-complete = NP
(B) NP-complete $\cap P = \varnothing$
(C) NP-hard = NP
(D) $P = NP$-complete

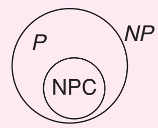
12. Which of the following statements are TRUE?

(i) The problem of determining whether there exists a cycle in an undirected graph is in P.
(ii) The problem of determining whether there exists a cycle in an undirected graph is in NP.
(iii) If a problem A is NP-Complete, there exists a non-deterministic polynomial time algorithm to solve A. **[2013]**

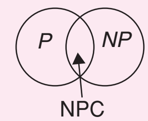
(A) 1, 2 and 3 (B) 1 and 2 only
(C) 2 and 3 only (D) 1 and 3 only

13. Suppose a polynomial time algorithm is discovered that correctly computes the largest clique in a given graph. In this scenario, which one of the following represents the correct Venn diagram of the complexity classes P, NP and NP-complete (NPC)? **[2014]**

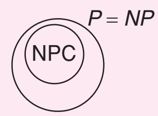
(A)



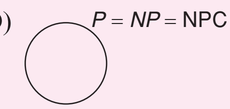
(B)



(C)



(D)



14. Consider a hash, table with 9 slots. The hash function is $h(K) = K \bmod 9$. The collisions are resolved by chaining. The following 9 keys are inserted in the order: 5, 28, 19, 15, 20, 33, 12, 17, 10. The maximum, minimum, and average chain lengths in the hash table, respectively, are **[2014]**

(A) 3, 0 and 1 (B) 3, 3 and 3
(C) 4, 0 and 1 (D) 3, 0 and 2

15. Consider two strings A = 'qpqrr' and B = 'pqprqrp'. Let x be the length of the longest common subsequence (not necessarily contiguous between A and B and let y be the number of such longest common subsequences between A and B. then $x + 10y$ = ______ **[2014]**

16. Suppose you want to move from 0 to 100 on the number line. In each step, you either move right by a unit distance or you take a *shortcut*. A shortcut is simply a pre-specified pair of integers i, j with $i < j$. Given a shortcut i, j if you are at position i on the number line, you may directly move to j. Suppose $T(k)$ denotes the smallest number of steps needed to move from k to 100. Suppose further that there is at most 1 shortcut involving any number, and in particular from 9 there is a shortcut to 15. Let y and z be such that $T(9) = 1 + \min(T(y), T(z))$. Then the value of the product yz is ______ **[2014]**

17. Consider the decision problem 2CNFSAT defined as follows: **[2014]**

$\{\phi \mid \phi$ is a satisfiable propositional formula in CNF with at most two literals per clause$\}$

For example, $\phi = (x_1 \vee x_2) \wedge (x_1 \vee x_3) \wedge (x_2 \vee x_4)$ is a Boolean formula and it is in 2CNFSAT.

The decision problem 2CNFSAT is

(A) NP-complete
(B) Solvable in polynomial time by reduction to directed graph reach ability.
(C) Solvable in constant time since any input instance is satisfiable.
(D) NP-hard, but not NP-complete

18. Consider a hash table with 100 slots. Collisions are resolved using chaining. Assuming simple uniform

hashing, what is the probability that the first 3 slots are unfilled after the first 3 insertions? **[2014]**

(A) $(97 \times 97 \times 97)/100^3$
(B) $(99 \times 98 \times 97)/100^3$
(C) $(97 \times 96 \times 95)/100^3$
(D) $(97 \times 96 \times 95)/(3! \times 100^3)$

19. Match the following **[2014]**

(P) prim's algorithm for minimum spanning tree	(i) Backtracking
(Q) Floyd-Warshall algorithm for all pairs shortest paths	(ii) Greedy method
(R) Mergesort	(iii) Dynamic programming
(S) Hamiltonian circuit	(iv) Divide and conquer

(A) P–iii, Q–ii, R–iv, S–i
(B) P–i, Q–ii, R–iv, S–iii
(C) P–ii, Q–iii, R–iv, S–i
(D) P–ii, Q–i, R–iii, S–iv

20. Given a hash table T with 25 slots that stores 2000 elements, the load factor ∝ for T is ________ **[2015]**

21. Language L_1 is polynomial time reducible to language L_2. Language L_3 is polynomial time reducible to L_2, which in turn is polynomial time reducible to language L_4. Which of the following is/are true? **[2015]**

(1) if $L_4 \in P$, then $L_2 \in P$
(2) if $L_1 \in P$ or $L_3 \in P$, then $L_2 \in P$
(3) $L_1 \in P$, if and only if $L_3 \in P$
(4) if $L_4 \in P$, then $L_1 \in P$ and $L_3 \in P$

22. The Floyd - Warshall algorithm for all -pair shortest paths computation is based on **[2016]**

(A) Greedy paradigm
(B) Divide-and-Conquer paradigm
(C) Dynamic Programming paradigm
(D) Neither Greedy nor Divide-and-Conquer nor Dynamic Programming paradigm.

23. Let A_1, A_2, A_3, and A_4 be four matrices of dimensions 10×5, 5×20, 20×10, and 10×5, respectively. The minimum number of scalar multiplications required to find the product $A_1 A_2 A_3 A_4$ using the basic matrix multiplication method is _____ . **[2016]**

24. Consider the following table:

Algorithms	Design Paradigms
(P) Kruskal	(i) Divide and Conquer
(Q) Quicksort	(ii) Greedy
(R) Floyd-Warshall	(iii) Dynamic Programming

Match the algorithms to the design paradigms they are based on. **[2017]**

(A) (P) ↔ (ii), (Q) ↔ (iii),(R) ↔ (i)
(B) (P) ↔ (iii), (Q) ↔ (i), (R) ↔ (ii)
(C) (P) ↔ (ii), (Q) ↔ (i), (R) ↔ (iii)
(D) (P) ↔ (i), (Q) ↔ (ii), (R) ↔ (iii)

25. Assume that multiplying a matrix G_1 of dimension $p \times q$ with another matrix G_2 of dimension $q \times \underline{r}$ requires pqr scalar multiplications. Computing the product of n matrices $G_1G_2G_3, ..., G_n$ can be done by parenthesizing in different ways. Define $G_i\ G_{i+1}$ as an explicitly computed pair for a given paranthesization if they are directly multiplied. For example, in the matrix multiplication chain $G_1G_2G_3G_4G_5G_6$ using parenthesization $(G_1(G_2G_3))(G_4(G_5G_6))$, G_2G_3 and G_5G_6 are the only explicitly computed pairs.

Consider a matrix multiplication chain $F_1F_2F_3F_4F_5$, where matrices F_1, F_2, F_3, F_4, and F_5 are of dimensions 2×25, 25×3, 3×16, 16×1 and 1×1000, respectively. In the parenthesization of $F_1F_2F_3F_4F_5$ that minimizes the total number of scalar multiplications, the explicitly computed pairs is/are: **[2018]**

(A) F_1F_2 and F_3F_4 only
(B) F_2F_3 only
(C) F_3F_4 only
(D) F_1F_2 and F_4F_5 only

26. Consider the weights and values of items listed below. Note that there is only one unit of each item.

Item no.	Weight (in Kgs)	Value (in Rupees)
1	10	60
2	7	28
3	4	20
4	2	24

The task is to pick a subset of these items such that their total weight is no more than 11 kgs and their total value is maximized. Moreover, no item may be split. The total value of items picked by an optimal algorithm is denoted by V_{opt}. A greedy algorithm sorts the items by their value-to-weight ratios in descending order and packs them greedily, starting from the first item in the ordered list. The total value of items picked by the greedy algorithm is denoted by V_{greedy}.

The value of $V_{opt} - V_{greedy}$ is ______. **[2018]**

Test

Algorithms (Part 2)

Time: 45 min.

Directions for questions 1 to 30: Select the correct alternative from the given choices.

1. The worst case running time of an algorithm means
(A) The algorithm will never take any longer.
(B) The algorithm will take less time than running time
(C) The algorithm will run in a finite time
(D) None of the above

2. Analyzing an algorithm involves
(A) Evaluating the complexity
(B) Validating the Algorithm
(C) Both A and B
(D) None of the above

3. $f(n) = \theta(g(n))$ is
(A) $g(n)$ is asymptotic lower bound for $f(n)$
(B) $g(n)$ is asymptotic tight bound for $f(n)$
(C) $g(n)$ is asymptotic upper bound for $f(n)$
(D) None of the above

4. Which case yields the necessary information about an algorithm's behaviour on a random input?
(A) Best-case (B) Worst-case
(C) Average-case (D) Both A and C

5. Algorithms that require an exponential number of operations are practical for solving.
(A) Only problems of very small size
(B) Problems of large size
(C) Problems of any size
(D) None of these

6. Problems that can be solved in polynomial time are called
(A) Tractable (B) Decidable
(C) Solvable (D) Computable

7. Problems that cannot be solved at all by any algorithm are known as
(A) Tractable (B) Undecidable
(C) Untractable (D) Unsolvable

8. Which of the following problems is decidable but intractable?
(A) Hamiltonian circuit (B) Traveling sales man
(C) Knapsack problem (D) All the above

9. Which method is used to solve recurrences?
(A) Substitution method
(B) Recursion-tree method
(C) Master method
(D) All the above

10. Consider the following
(i) Input
(ii) Output
(iii) Finiteness
(iv) Definiteness means clear and unambiguous
(v) Effectiveness
Which of the following is not a property of an algorithm?
(A) (iv) only (B) (iv) and (v) only
(C) (iii) and (iv) only (D) None of the above

11. Finiteness of an algorithm means
(A) The steps of the algorithm should be finite
(B) The algorithm should terminate after finite time
(C) Algorithm must terminate after a finite number of steps
(D) Algorithm should consume very less space

12. Asymptotic analysis on efficiency of algorithm means
(A) The efficiency of the algorithm on a particular machine
(B) How the running time of an algorithm increases as the size increases without bound
(C) How efficiently the algorithm is applied to solve a problem without thinking of input size.
(D) None of the above

13. What is the input size of a problem?
(A) Number of variables used to solve the problem
(B) Number of constants used to solve the problem
(C) it is problem specific that is in case of graph it is number of edges and vertices and so on.
(D) None of these

14. (i) An algorithm must take input
(ii) An algorithm must give out put
Which is true in the following options?
(A) (i) Only (B) (ii) Only
(C) (i) and (ii) Only (D) None of the above

15. As n θ°
Which of the following is efficient?
(A) $\theta(n^3)$ (B) $\theta(n^2)$
(C) $\theta(2^n)$ (D) $\theta(n^4)$

16. Suppose
$T_1(n) = O(f(n))$
$T_2(n) = O(f(n))$
which of the following is true,.
(A) $T_1(n) + T_2(n) = O(f(n))$ (B) $\dfrac{T_1(n)}{T_2(n)} = 0(1)$
(C) $T_1(n) = 0(T_2(n))$ (D) None of these

17. The following program computes n!
Find the complexity?
Input: A non-negative integer
Output: Value of n!
If $n = 0$ return 1
Else return $F(n - 1)\ \theta n$
(A) $\theta(n)$
(B) $\theta(n \log n)$
(C) $\theta(n^2)$
(D) $\theta(n^3)$

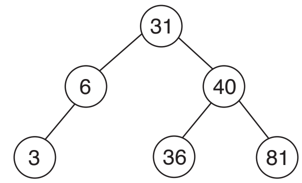
18. Which of the following functions are often referred as 'exponential growth function'?
(A) 2^n, $\log n$
(B) 2^n, $n!$
(C) $n!$, $n \log n$
(D) $n!$, $\log n$

19. Consider the following code
sort (a, n)
```
{
    for i = 1 to n do
    {
            j = i;
    for k = i + 1 to n do
            if (a[k] < a [j]) then j = k;
            t = a[i];
            a[i] = a[j];
            a[j] = t;
            }
    }
```
The above code implements which sorting?
(A) Merge sort
(B) selection sort
(C) Insertion sort
(D) Radix sort

20. Assume that the number of disks in a 'Towers of Hanoi problem' is 'n', with '3' towers, Initially all disks are placed on tower 1, to get the largest disk are placed on tower 1, to get the largest disk to the bottom of 2nd tower, How many moves are required? ($\theta n = 3$)
(A) n
(B) $(n - 1)$
(C) $(n + 1)$
(D) $2n$

21. Each new term in Fibonacci sequence is obtained by taking the sum of the two previous terms. The first term of the sequence is $f_0 = 0$, and the second term $f_1 = 1$. Which of the following gives Fibonacci sequence?
(A) $f_n = f_{n+1} + f_{n-2}$, $n \geq 2$
(B) $f_n = f_{n-1} + f_{n-2}$, $n \geq 2$
(C) $f_n = f_{n-1} + f_{n+1}$, $n \geq 2$
(D) All the above

22. Consider the binary search tree



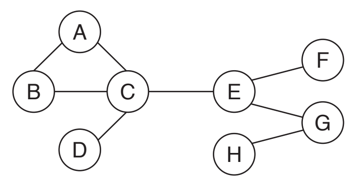
Delete node '31', what would be the parent node in the new binary search tree?
(A) 36
(B) 40
(C) 81
(D) 6

23. Consider the given array [4, 6, 7, 8, 21, 9, 3, 10, 13, 16, 31] after performing '1' delete max operation, on the max heap. What would be the sequence of elements in the array?
(A) 9, 21, 13, 16, 3, 7, 10, 8, 4, 6
(B) 21, 9, 13, 16, 7, 3, 10, 8, 4, 6
(C) 21, 9, 13, 16, 3, 7, 10, 8, 4, 6
(D) 21, 9, 13, 16, 7, 3, 10, 4, 8, 6

24. Consider the given Di-graph

How many strongly connected components does the above graph contain?
(A) 1
(B) 2
(C) 3
(D) many

25. Consider the given graph



Which of the following shows the adjacency matrix of the above graph?

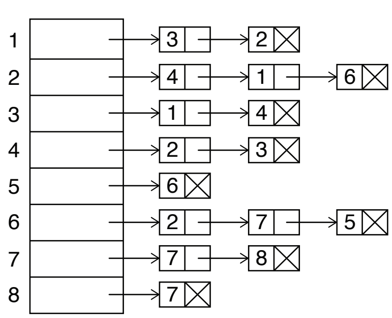
(A)
$$
\begin{array}{c|cccccccc|}
 & A & B & C & D & E & F & G & H \\
\hline
A & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\
B & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
C & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\
D & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
E & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 \\
F & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
G & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\
H & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0
\end{array}
$$

(B)
$$\begin{array}{cc} & \begin{matrix} A & B & C & D & E & F & G & H \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \\ E \\ F \\ G \\ H \end{matrix} & \begin{bmatrix} 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \end{bmatrix} \end{array}$$

(C)
$$\begin{array}{cc} & \begin{matrix} A & B & C & D & E & F & G & H \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \\ E \\ F \\ G \\ H \end{matrix} & \begin{bmatrix} 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix} \end{array}$$

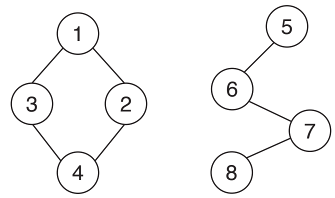
(D)
$$\begin{array}{cc} & \begin{matrix} A & B & C & D & E & F & G & H \end{matrix} \\ \begin{matrix} A \\ B \\ C \\ D \\ E \\ F \\ G \\ H \end{matrix} & \begin{bmatrix} 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 \end{bmatrix} \end{array}$$

26. Consider the given adjacency list

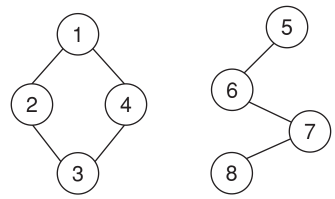


The above list is representation of which of the following graph?

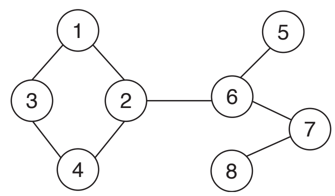
(A)



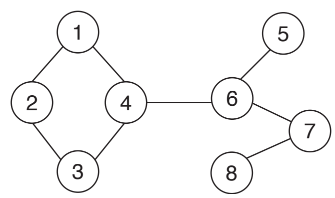
(B)



(C)



(D)



27. Which of the following is FALSE?

(A) In dynamic programming an optimal sequence of decisions is obtained by making explicit appeal to the principle of optimality

(B) In greedy method only one decision sequence is generated.

(C) In dynamic programming, many decision sequences may be generated.

(D) In greedy method many decision sequences are generated.

28. Consider an array $a[n]$ of 'n' numbers that has '$n/2$' distinct elements and '$n/2$' copies of another element, to identify that repeated element, how many steps are required in the worst case?

(A) $n/2$ (B) $n/2 + 1$

(C) $n/2 + 2$ (D) n

29. Match the following, for a very large value of 'n'

I. $36n^3 + 2n^2$

II. $5n^2 - 6n$

III. $n^{1.001} + n \log n$

P. $\theta(n^2)$

Q. $|(n^3)$

R. $\theta(n^{1.001})$

(A) I – P, II – Q, III – R (B) I – Q, II – P, III – R

(C) I – R, II – Q, III – P (D) I – R, II – P, III – R

30. Consider the following code

```
    T(a, n)
{
  for i = 1 to n - 1 do
     for j = i + 1 to n do
           {
                  t = a[i, j];
                  a[i, j] = a[j, i];
                  a[j, i] = t;
           }
  }
```

The above code performs

(A) Matrix multiplication
(B) Matrix addition
(C) Matrix transpose
(D) Matrix chain multiplication

Answers Keys

ALGORITHMS TEST I

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. Consider the given properties of Asymptotic Notations:
I. $f(n) = \theta(g(n))$ and $g(n) = \theta(h(n))$
$\Rightarrow$ $f(n) = \theta(h(n))$
II. $f(n) = \theta(g(n))$ if and only if $g(n) = \theta(f(n))$
III. $f(n) = O(g(n))$ if and only if $g(n) = \Omega(f(n))$
IV. $f(n) = O(g(n))$ if and only if $g(n) = O(f(n))$
Which of the following are valid?
(A) I, II only (B) I, II, III only
(C) II, III only (D) I, II, III and IV

2. Consider the given Recurrence Relation
$T(n) = 2^n\, T(n/3) + n$
Which of the following is TRUE?
(A) Master theorem cannot be applied because 'a' is not constant.
(B) It comes under case 1 of Master theorem.
(C) It comes under case 2 of Master theorem.
(D) It comes under case 3 of Master theorem.

3. Let 'n' be the number of elements in the queue, then What is the Time complexity of following operations respectively, Enqueue( ), Dequeue ( ), IsEmptyQueue ( ), Delete Queue( )?
(A) $O(n)$, $O(1)$, $O(1)$, $O(n)$
(B) $O(1)$, $O(1)$, $O(n)$, $O(1)$
(C) $O(1)$, $O(1)$, O(1), $O(1)$
(D) $O(n)$, $O(n)$, $O(n)$, $O(1)$

4. Which of the following are Applications of Binary Trees?
I. Huffman coding trees are used in data compression Algorithms.
II. Priority Queues support search and deletion of minimum or maximum on 'n' number of items in (log n) time.
III. Expression trees are used in compilers.
IV. Binary search Tree supports search, insertion and deletion on 'n' number of items in (log n) time (average case)
(A) I, II only (B) I, III, IV only
(C) I, II, III only (D) I, II, III and IV

5. A Traversal is defined as follows:
1. Visit the root
2. While traversing Level 'i', keep all the elements at level '$i + 1$' in queue.
3. Go to the next Level and visit all the nodes at that level.
4. Repeat this until all the levels are completed.
The above defined traversal is
(A) Depth First Traversal
(B) Level order Traversal
(C) Binary Tree Traversal
(D) Binary search Tree Traversal

6. How many different binary trees are possible with '8' nodes?
(A) 256 (B) 128
(C) 248 (D) 64

7. A binary search tree is generated by inserting in order the following integers 66, 72, 46, 48, 9, 8, 40, 36, 18, 7, 5, 91, 88, 49, 6. The number of nodes in the Left sub tree and Right sub tree of the root respectively.
(A) (8, 6) (B) (9, 5)
(C) (10, 4) (D) (11, 3)

8. For a Full Binary tree of height 'h', the sum of the heights of all nodes is ________ ('n' is number of nodes)?
(A) $n - (h - 1)$ (B) $n - (h + 1)$
(C) $n + (h - 1)$ (D) $n + (h + 1)$

9. A graph 'G' has 29 edges and its complement $\bar{G}$ has 7 edges, what is the number of vertices present in graph G?
(A) 7 (B) 8
(C) 9 (D) 10

10. Consider the given statements:
I. Uses priority queue to store unvisited vertices by distance from source.
II. It uses greedy method, means pick the next closest vertex to the source.
III. Does not work with negative weights.
The above statements describe
(A) Bellman Ford Algorithm
(B) Dijkstra's Algorithm
(C) Breadth First search Algorithm
(D) Kruskals Algorithm

11. A complete bipartite graph $k_{m,n}$ is a bipartite graph that has each vertex from one set is adjacent to each vertex to another set, what is the minimum 'vertex cover' for $k_{m,n}$ graphs?
(A) MAX(m, n) (B) MIN(m, n)
(C) m (D) n

12. What is the number of Regions present in the bipartite graph $K_{5,2}$?
(A) 4 (B) 5
(C) 6 (D) 7

13. Consider the following:

	Best Case	Average Case	Worst Case
I.	$O(n)$	$O(n^2)$	$O(n^2)$
II.	$O(n \log n)$	$O(n \log n)$	$O(n \log n)$

Which of the following is TRUE?
(A) Merge sort-II, Selection sort-II
(B) Merge sort-II, Heap sort-II
(C) Heap sort-I, Insertion sort-I
(D) Bubble sort-I, Insertion sort-II

14. Which of the following Algorithm uses Divide-and-Conquer strategy?
(A) Merge sort
(B) Quick sort
(C) Binary search and strassens multiplication
(D) All the above

15. For merging two sorted Lists of sizes 'K' and 'L' into a sorted list of size $K + L$, what is the number of comparisons required?
(A) $O(K)$ (B) $O(L)$
(C) $O(K*L)$ (D) $O(K + L)$

16. Consider the following:
$f(n) = n \log n$
$g(n) = \log (n!)$
$h(n) = 2^{\log_2^n}$
Which of the following is TRUE according to Rate of Growth?
(A) $g(n) \in \Omega\, h(n)$ and $g(n) \in O(f(n))$
(B) $g(n) \in O(f(n))$ and $f(n) \in \Omega(g(n))$
(C) $g(n) \in \Omega(f(n))$ and $f(n) \in \Omega(g(n))$
(D) $h(n) \in O(g(n))$ and $g(n) \in O(f(n))$

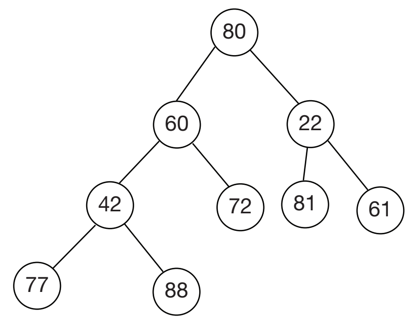
17. Consider the given code:
```
y = y + z;
for (i = 1; i < = n; i++)
k = k + 2;
for (i = 1; i < = n; i++)
{
for(j = 1; j < = n; j++)
x = x + 1;
}
```
What is the time complexity of the given code?
(A) $O(n^3)$ (B) $O(n^2)$
(C) $O(n \log n)$ (D) $O(n^2 \log n)$

18. Consider the given Recurrence Relation
$$T(n) = 3T\left(\frac{n}{9}\right) + n^{0.52}.$$
What is the Time complexity?
(A) $O(n)$ (B) $O(n^2)$
(C) $O(n^{0.52})$ (D) $O(\sqrt{n})$

19. Consider an empty stack of integers. The numbers 6, 7, 1, 4, 3, 2, 8, 9 are pushed on to the empty stack in the above given order from Right to Left. Let Z denote a PUSH operation and 'W' denote a *POP* operation. Which of the following is the sequence of integers Popped out after performing ZZZZWWZZWWZW?
(A) 3, 2, 4, 1, 7 (B) 3, 2, 1, 4, 9
(C) 3, 2, 1, 4, 8 (D) 3, 2, 1, 4, 7

20. The following sequence of operations is performed on a stack, PUSH(70), PUSH(50), POP, PUSH(30), PUSH(50), PUSH(70), POP, POP, PUSH(70), POP, POP, what is the sequence of values popped out?
(A) 50, 70, 50, 70, 70
(B) 50, 50, 70, 30, 70
(C) 50, 70, 50, 70, 30
(D) 50, 70, 50, 30, 70

21. Assume an algorithm for printing the level order data in Reverse order, for the Binary tree shown below:



(A) 80, 60, 22, 42, 72, 81, 61, 77, 88
(B) 80, 22, 60, 61, 81, 72, 42, 88, 77
(C) 77, 88, 42, 72, 81, 61, 60, 22, 80
(D) 88, 77, 61, 81, 72, 42, 22, 60, 80

22. Consider the given code:
```
int fun(struct BinaryTreeNode *root1,
struct Binary Tree Node *root2)
{
if(root1 = = NULL & & root2 = = NULL)
return 1;
if(root1 = = NULL || root2 = = NULL)
return 0;
return (root1 → data = = root2 →
   data &&
fun(root1 → left, root2 → left) &&
fun(root1 → right, root2 → right));
}
```
The above code describes, which of the following task?
(A) Finding the number of nodes with only one child
(B) Finding the number of nodes in a Tree.
(C) Finding, whether two binary trees are structurally identical or not
(D) Finding the number of Leaf nodes in a tree.

23. We are given a set of '6' distinct elements and an unlabelled binary tree with '6' nodes. In how many ways can we populate the tree with the given set, so that it becomes a binary search tree?
(A) 58 (B) 720
(C) 360 (D) 132

24. A binary tree is a tree data structure in which each node has atmost 2 children, that is, the degree of each node can be atmost '2'. If a binary tree has 'n' leaf nodes, then the number of nodes of degree 2 is?

(A) $n - 1$ (B) $2n - 1$
(C) $n + 1$ (D) $\frac{n}{2}$

25. For a 5-ary tree (each node can contain maximum of 5 children), what is the maximum possible height with 50 nodes, Assume that height of a single node is '0'?
(A) 25 (B) 30
(C) 49 (D) 50

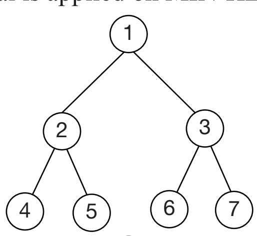
26. For a 7-ary tree (each node can contain maximum of 7 children), what is the maximum possible height with 60 nodes, If we have a restriction that atleast one node should have 7 children?
(A) 14 (B) 21
(C) 49 (D) 53

27. For a K-ary tree (each node can contain maximum of K children), what is the maximum possible nodes at height 'h'?
(A) Kh^{+1} (B) K^h
(C) Kh^{-1} (D) $2K^h$

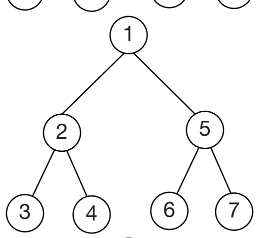
28. Consider any completer Binary tree, what are the minimum and maximum number of elements interms of height 'h'?
(A) 2^{h+1} and 2^{h+2} (B) 2^h and $2^{h+1} - 1$
(C) $2^{h+1} - 1$ and $2^{h+1} + 1$ (D) 2^h and 2^{h+1}

29. Which of the following MIN-HEAP displays the elements in sequence (ascending order) if preorder traversal is applied on MIN-HEAP?

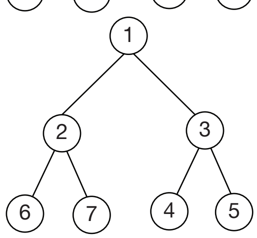
(A)



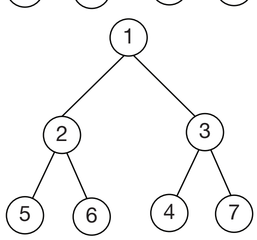
(B)



(C)

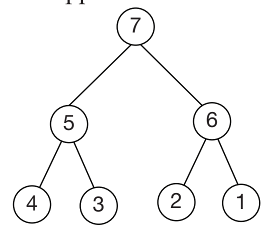


(D)

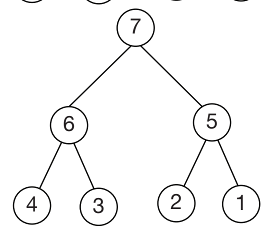


30. Which of the following MAX-HEAP displays the elements in sequence (descending order) if preorder traversal is applied on MAX-HEAP?

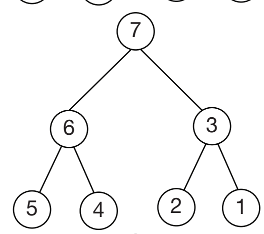
(A)



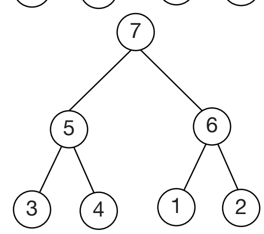
(B)



(C)



(D)



31. What is the minimum and maximum number of nodes that exist in MIN-HEAP/MAX-HEAP interms of height 'h'?
(A) 2^{h-1} and 2^{h+1} (B) 2^{h-1} and 2^h
(C) 2^h and $2^{h+1} - 1$ (D) $2^{h+1} - 1$ and 2^{h+1}

32. Which of the following cannot be the partition of array elements by using Quick sort Algorithm?

(A) $T(n) = T\left(\frac{6n}{10}\right) + T\left(\frac{4n}{10}\right) + \theta(n)$

(B) $T(n) = T\left(\frac{4n}{5}\right) + T\left(\frac{n}{5}\right) + \theta(n)$

(C) $T(n) = T(n-1) + T(1) + \theta(n)$

(D) $T(n) = T\left(\frac{4n}{5}\right) + T\left(\frac{4n}{5}\right) + \theta(n)$

33. A stable sorting is defined as, Assume that A is an array to be sorted, X and Y are having the same key and X appears earlier in the array than Y. That means X is at $A[i]$ and Y is at $A[j]$, where $i < j$, an algorithm is said to be stable if in the output X precedes Y. Which of the following is not stable sorting?
(A) Bubble sort (B) Insertion sort
(C) Merge sort (D) Quick sort

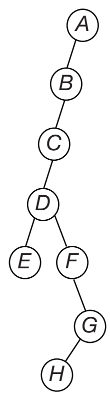
Common Data for Questions 34 and 35:
Consider the given Inorder, preorder, postorder traversals of a tree, but it is not known which is what order

I. *ABCDEGFH*
II. *EDGHFCBA*
III. *EHFGDCBA*

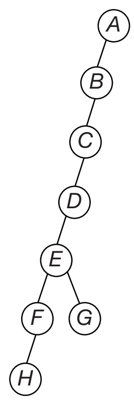
34. Which of the following is TRUE?
(A) I is pre order and II is post order
(B) I is pre order and III is In order
(C) I is pre order and II is In order
(D) II is post order and III is In order

35. Which of the following is the correct tree for the traversals given in the above question?

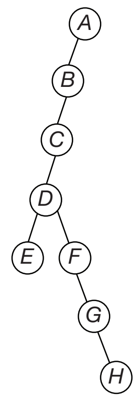
(A)



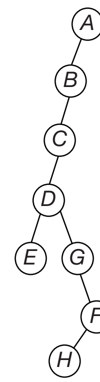
(B)



(C)



(D)



Answer Keys

1. B	**2.** A	**3.** C	**4.** D	**5.** B	**6.** C	**7.** D	**8.** B	**9.** C	**10.** B

Hints and Explanations

1. **Transitivity:**
$f(n) = \theta(g(n))$ and $g(n) = \theta(h(n))$
$\Rightarrow$ $f(n) = \theta(h(n))$ valid for Ω and O notations also.
Symmetry:
$f(n) = \theta(g(n))$ if and only if $g(n) = \theta(f(n))$
Transpose symmetry:
$f(n) = O(g(n))$ if and only if $g(n) = \Omega\ (f(n))$.
Choice (B)

2. $T(n) = aT(n/b) + f(n)$
'a' has to be constant. Choice (A)

3. Time complexity of EnQueue( ) = $O(1)$
Time complexity of DeQueue( ) = $O(1)$
Time complexity of IsEmptyQueue( ) = $O(1)$
Time complexity of DeleteQueue( ) = $O(1)$.
Choice (C)

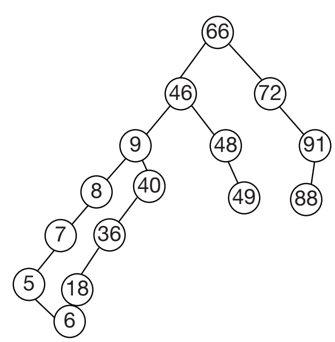
4. All the given statements I, II, III and IV are Applications of Binary Trees. Choice (D)

5. **Depth First Traversal:**
1. Pre order Traversal
2. In order Traversal
3. Post order Traversal

Breadth First Traversal:
1. Level order Traversal
The traversal defined in the given Questions is Level order traversal. Choice (B)

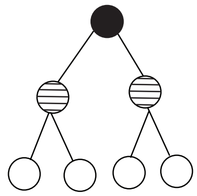
6. With 'n' nodes, it will have the maximum combinations of different trees.
$\Rightarrow$ $2^8 - 8 = 256 - 8 = 248$. Choice (C)

7. Root is '66', the numbers less than 66 will appear in Left sub tree and greater numbers appear in Right sub tree.
$\therefore$ (11, 3)

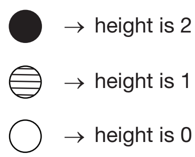


Choice (D)

8. Let us consider the following Full binary tree
$n = 7$ nodes



$n - (h + 1)$
$\Rightarrow \quad 7 - (2 + 1) = 7 - 3 = 4$
$h = 2$ (height)

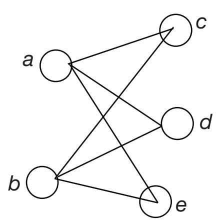


$2 + 1 + 1 + 0 + 0 + 0 + 0 = 4.$ Choice (B)

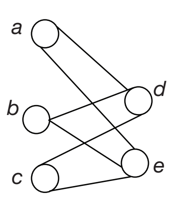
9. $\bar{G}(e) = \dfrac{V(V-1)}{2} - G(e)\; V^2 - V - 72 = 0$
$\Rightarrow \quad V(V - 9) + 8(V - 9) = 0$
$\Rightarrow \quad V = 9.$ Choice (C)

10. The given statements describe Dijkstra's Algorithm.
Choice (B)

11. Let us take
$k_{2,3}$



Minimum vertex cover = $\{a, b\}$
$K_{3,2}$



Minimum vertex cover = $\{d, e\}$
$\therefore \quad$ MIN(m, n). Choice (B)

12. Eulers formula: $|V| + |R| - |E| = 2$
$k_{5,2}$ is planar graph, As we know,
The number of vertices in $k_{m,n}$ graph is $m + n$
$\therefore \quad k_{5,2}$ has 7 vertices
The number of edges in $k_{m,n}$ graph is $m*n$
$\therefore \quad k_{5,2}$ has 10 edges
$|V| + |R| - |E| = 2$
$7 + R - 10 = 2$
$R - 3 = 2$
$R = 5$ Choice (B)

13. Merge sort - II
Heap sort - II
Insertion sort - I, Bubble sort - I, selection sort - I.
Choice (B)

14. All the algorithms follow Divide-and-conquer approach. Choice (D)

15. In the worst case, if there are 4 elements in each list, consider the following lists (if $(i < j)$
print 'i'
else
print 'j')

2 4 6 8	1 3 5 7
i	j

1 comparison

2 4 6 8	1 3 5 7
i	j

1 comparison

2 4 6 8	1 3 5 8
i	j

1 comparison

2 4 6 8	1 3 5 8
i	j

$\therefore \quad$ Almost $(K + L)$ comparisons are required.
Choice (D)

16. $n \log n \geq \log (n!) \geq 2^{\log_2^n}$
option (D) is true.
$2^{\log_2^n} \leq c * \log (n!)$
$\log (n!) \leq c * n \log n.$ Choice (D)

17. $y = y + 2$; // constant time
for ($i = 1$; $i <= n$; $i++$) //executed '$n + 1$' times
$k = k + 2$; // executes n times
for ($i = 1$; $i \leq n$; $i++$)//outer loop executed '$n + 1$' times
for ($j = 1$; $j <= n$; $j++$)//inner loop executed '$n(n + 1)$' times
$x = x + 1$; // executes n times
Total time $= C_0 + C_1 n + C_2 n^2 = O(n^2)$. Choice (B)

18. $T(n) = 3T\left(\dfrac{n}{9}\right) + n^{0.52}$

$T(n) = aT\left(\dfrac{n}{b}\right) + f(n)$

$a = 3, b = 9, f(n) = n^{0.52}$
compare
$n^{\log_b^a}$ Vs $f(n)$
$n^{\log_9^3}$ Vs $n^{0.52}$
$n^{\log_9^{\sqrt{9}}}$ Vs $n^{0.52}$ $f(n)$ is greater than $n^{\log_b^a}$
case 3 of master theorem, so the time complexity is
$T(n) = \theta(f(n))$
$\Rightarrow \quad \theta(n^{0.52})$. Choice (C)

19. Given Integers
6, 7, 1, 4, 3, 2, 8, 9
From Right to Left:
9, 8, 2, 3, 4, 1, 7, 6
Z Z Z Z(4 push operations)

3
2
8
9

2 pop operations
⇒ 3, 2
Again 2 push operations

1
4
8
9

2 pop operations
⇒ 1, 4
One push operation

7
8
9

One pop operation
⇒ 7
∴ popped integers are 3, 2, 1, 4, 7. Choice (D)

20.

50
70

⇒ pop '50'

70
50
30
70

⇒ pop 70, 50

70
30
70

⇒ pop 70, 30
∴ popped sequence = 50, 70, 50, 70, 30.
Choice (C)

21. Level order data in reverse means,
Bottom level data elements from Left to Right should be taken first.
Level order Traversal is, 77, 88, 42, 72, 81, 61, 60, 22, 80. Choice (C)

22. Given two binary trees,
Returns true if they are structurally identical.
∴ If both trees are NULL then return true.
∴ If both trees are not NULL, then compare data and recursively check left and right subtree structures.
Choice (C)

23. With '6' distinct elements and 6 unlabelled binary tree nodes, we can have,

$$n = 6,\ \frac{1}{n+1}\times 2n_{C_n}$$

$$\frac{1}{6+1}\times\frac{(2\times 6)!}{(12-6)!\times 6!}\ \frac{1}{7}\times\frac{12\times 11\times 10\times 9\times 8\times 7}{6\times 5\times 4\times 3\times 2}$$

$= 11 \times 2 \times 3 \times 2 = 132.$ Choice (D)

24. A binary tree with 'n' leaves have $(n-1)$ internal nodes. So $(n-1)$ nodes will have degree '2'. Choice (A)

25. In 5-ary tree each node can contain 0 to 5 children and to get maximum height, we have to keep only one child for each parent, with 50 nodes the maximum possible height we can get is 49. Choice (C)

26. If we have a restriction that atleast one node should have 7 children, then we keep one node with 7 children and remaining all nodes with 1 child. In this case, with 'n' nodes the maximum possible height is $(n-7)$.
∴ $60 - 7 = 53$. Choice (D)

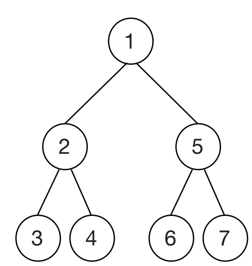
27. If we want to get minimum height, then we need to fill all nodes with maximum children.
Lets take a 4-ary tree.

Height (h)	Maximum Nodes at height, $h = 4^h$
0	1
1	4
2	4 × 4
3	4 × 4 × 4

Choice (B)

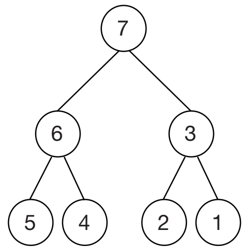
28. In a complete binary tree, all levels contain full nodes except possibly the lowest level.
Maximum = $2^{h+1} - 1$ elements
Minimum = 2^h. Choice (B)

29. Pre order traversal on the following Min-Heap produces elements in ascending order



∴ 1 2 3 4 5 6 7. Choice (B)

30. Pre order Traversal on the following MAX-HEAP produces elements in sequence (descending order)



∴ Pre order = 7 6 5 4 3 2 1. Choice (C)

31. A Heap is a complete binary tree. All the levels, except the lowest, are completely full. So the heap has atleast 2^h elements and atmost $2^{h+1} - 1$ elements. Choice (C)

32. The given array is partitioned into two non-empty sub arrays
In Option (D) 80 percent of elements are in First sub array that means in the second part of array there should be 20 percent elements that is $T\left(\frac{n}{5}\right)$ instead of $T\left(\frac{4n}{5}\right)$. Choice (D)

33. **Quick sort:**
The partitioning step can swap the location of records many times, and thus 2 elements with equal value could swap position in the final output.
Choice (D)

34. Pre order = $A\ B\ C\ D\ E\ G\ F\ H$
In order = $E\ D\ G\ H\ F\ C\ B\ A$
Post order = $E\ H\ F\ G\ D\ C\ B\ A$.
Choice (C)

35. The tree given in option (D) is correct.
Choice (D)

Algorithms Test 2

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. What is the worst case time complexity of search operation on unordered and ordered List, using Linear search Algorithm respectively?

(A) $O(n)$ and $O(1)$
(B) $O(n)$ and $O(\log n)$
(C) $O(n)$ and $O(n)$
(D) $O(\log n)$ and $O(\log n)$

2. Which of the following is the Recurrence relation for binary search and What is the time complexity of that Recurrence Relation respectively?

(A) $T(n) = T(n/2) + \theta(n)$ and $\theta(\log n)$
(B) $T(n) = T(n/2) + \theta(1)$ and $\theta(\log n)$
(C) $T(n) = T(n/2) + \theta(1)$ and $\theta(n \log n)$
(D) $T(n) = T(n/2) + \theta(n)$ and $\theta(n \log n)$

3. Given 'n' numbers randomly, what is the time complexity of calculating median?

(A) $O(\log n)$ (B) $O(n \log n)$
(C) $O(n^2)$ (D) $O(n^2 \log n)$

4. Given an array of 'n' elements, what is the time complexity of Finding a number which appears more than $(n/2)$ times in the given array (if it exists)?

(A) $O(n/2)$ (B) $O(n \log n)$
(C) $O(\log n)$ (D) $O(n^2)$

5. What is the number of comparisons performed to find the smallest and largest keys in an array A of even size and odd size of n and $(n + 1)$ elements respectively?

(A) $\frac{3n}{2} - 2$ and $\frac{3n}{2}$ (B) $\frac{3n}{2}$ and $\frac{3n}{2} - 2$
(C) $\frac{3n}{2} - 2$ and $\frac{3n}{2} - \frac{3}{2}$ (D) $\frac{3n}{2} - 2$ and $\frac{3n}{2} + 1$

6. What is the time complexity of an algorithm, for finding Fourth Largest element in the given input list of n elements?

(A) $2n - 3$ (B) $2n - 4$
(C) $2n - 5$ (D) $2(2n - 5)$

7. The Bellman-Ford algorithm solves the single-source shortest path problem in the case in which edge weights may be negative, what is the time complexity of running Bellman-Ford Algorithm?

(A) $O(V^2)$ (B) $O(V * E)$
(C) $O(V + E)$ (D) $O(E \log V)$

8. Construct a Hash table with size '8', hash function is $h(k) = (2k + 1) \bmod 8$, with elements 3, 8, 16, 9, 1, 4. What is the Location of key '4'?

(A) Location 1 (B) Location 2
(C) Location 4 (D) Location 5

9. Consider the given two strings str1 and str2.
Let str1 = < A B R A C A D A B R O A >
str2 = < Y A B B A D A B B A D O O B A >
Then the length of longest common subsequence would be ___________.

10. Which of the following is the regular expression to the string of the form $a^m b^{2n} c^{3p}$, where $m, n, p \geq 2$.

(A) $a^* b^* c^*$
(B) $aa^* (bb)(bb)^* ccc(ccc)^*$
(C) $aaa^* (bbbb)(bb)^* cccccc(ccc)^*$
(D) $aa(aa)^* (bbbb)(bbbb)^* cccccc (cccccc)^*$

11. Which of the following statements are TRUE.

(i) $3n + 1 \in O(3^n)$
(ii) $100n \log n \in O(n \log n)$
(iii) $2n \neq O(n^k)$; K is a constant.
(iv) $0 < i < j$; $n^j \in O(n^i)$

(A) (i, ii, iii) (B) (i, ii, iv)
(C) (ii, iii) (D) (i, ii)

12. Suppose that we want to encode strings over the 8-character alphabet $C = \{a, b, c, d, e, f, g, h\}$ by using Fixed Length Encoding, and the frequencies are given below:
$a - 11, b - 13, c - 12, d - 10, e - 9, f - 7, g - 5, h - 3$
The number of bits required to store string '*abfeg*' is _______.

13. In Depth First search Algorithm, _____ number of times all the vertices are accessed, in a graph $G(V, E)$:

(A) one (B) two
(C) three (D) four

14. What is the number of substrings of any length excluding empty string, of a given string of length 'n', that can be formed?

(A) n^2 (B) $n \log n$
(C) $\frac{n(n+1)}{2}$ (D) $\frac{n(n-1)}{2}$

15. What is the time complexity of running Bellman-Ford Algorithm on K-Regular graph ($K \geq 3$)?

(A) $O(n^2 \log n)$
(B) $O(n^3)$
(C) $O(2^n)$
(D) $O(n \log n)$

16. Consider the given array

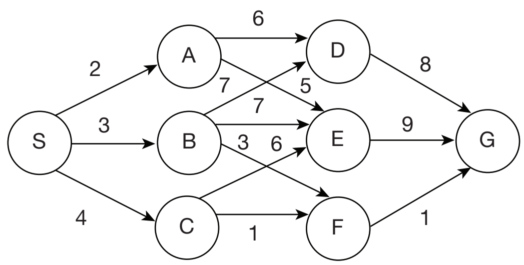
4	2	6	4	2	6

For finding the first element in the array which is repeated, which of the following is TRUE?

(A) Sort the given array, in this sorted array, the first element is the repeated element.
(B) Use brute force method, every element is checked with all the other elements, return the first element which is repeated.

(C) Sort the given array in descending order, in this sorted array the first element is the repeated element.
(D) Both (A) and (B)

17. Consider the given multi stage graph



What is the shortest path from node 'S' to node 'G' using Greedy Approach?

(A) 16 (B) 6
(C) 7 (D) 19

18. Consider the same graph given in the above question, What is the shortest path from node 'S' to node 'G' using Dynamic programming?

(A) 6 (B) 7
(C) 16 (D) 19

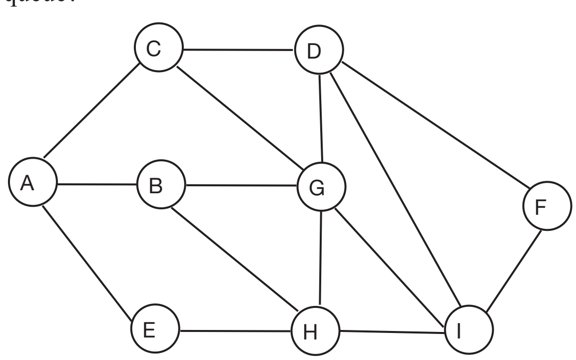
19. Consider the given Huffman code:

110 100 11110 110

Huffman code is constructed for the following set of letters whose frequencies are based on the first 8 Fibonacci numbers?
$a-1, b-1, c-2, d-3, e-5, f-8, g-13, h-21$
Which of the following sequence of letters correctly matches the given Huffman code?

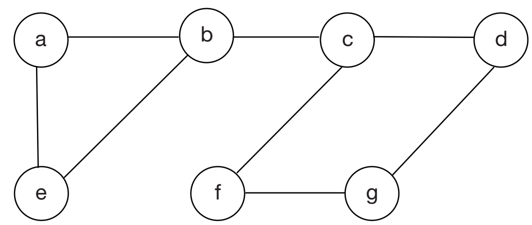
(A) $f\,g\,h\,a\,d$ (B) $f\,g\,h\,c\,e$
(C) $f\,g\,h\,d\,f$ (D) $f\,g\,h\,d\,e$

20. Implement Breadth-First search on the graph given below, starting at vertex A. Assume that the adjacency lists are in sorted order. Example when exploring vertex E, the algorithm considers the edge $E-B$, before $E-C$, $E-F$, $E-G$, or $E-H$. Which of the following is the order of vertices that are enqueued on the FIFO queue?



(A) A, B, C, E, G, H, I, D, F
(B) A, B, C, E, H, G, D, I, F
(C) A, B, C, D, E, G, H, I, F
(D) A, B, C, E, G, H, D, I, F

21. Consider the given graph



Implement Depth First search Algorithm on the given graph, which of the following cannot be the sequence of poped elements?

(A) a, b, c, d, g, f, e (B) c, d, g, f, b, a, e
(C) c, d, g, f, b, e, a (D) f, g, d, c, a, e, b

22. Consider the graph given in the above Question, Implement Breadth First search on the given graph, Which of the following cannot be the sequence of nodes Dequeued?

(A) d, c, g, f, b, a, e (B) g, f, d, c, b, a, e
(C) f, c, g, b, d, a, e (D) e, a, c, d, g, f, b

23. The keys 22, 31, 46, 42, 58, 61, 64, 71, 83, 97 are inserted into an initially empty hash table of length 10 using open addressing with hash function $h(k) = k$ mod 10 and Linear probing. What is the Resultant hash table?

(A)

0	1	2	3	4	5	6	7	8	9
83	31	22	42	61	64	46	71	58	97

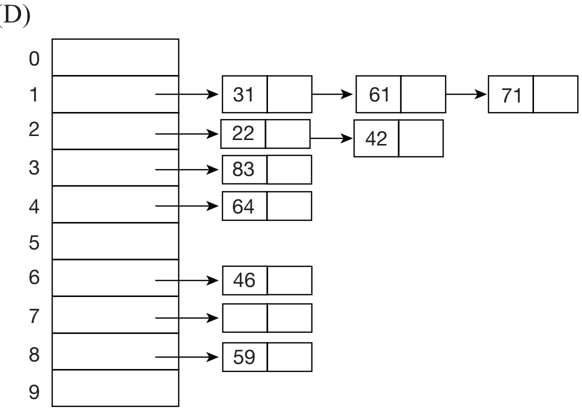
(B)

0	1	2	3	4	5	6	7	8	9
97	31	22	42	61	64	46	71	58	83

(C)

0	1	2	3	4	5	6	7	8	9
	31 61 71	22 42	83	64		46	97	58	

(D)



24. What is the number of bits required to store a file of 200 characters, The frequencies of *a*, *b*, *c*, *d* are as follows *a* – 25, *b* – 50, *c* – 100, *d* – 25 using Fixed Length Encoding?

(A) 200 bits (B) 800 bits
(C) 400 bits (D) 600 bits

25. Consider the data given in the above question what is the number of bits required to store the file using variable Length Encoding scheme?

(A) 200 bits (B) 250 bits
(C) 300 bits (D) 350 bits

26. Consider the tasks T_1, T_2, T_3, T_4, T_5. Following table shows, Deadlines and profits of the given tasks

Task	Deadline	Profit
T_1	2	20
T_2	2	50
T_3	1	30
T_4	1	40
T_5	4	60

Which tasks are not executed?

(A) T_1 and T_2 (B) T_1 and T_5
(C) T_1 and T_3 (D) T_2 and T_5

27. For the data given in the above question, what is the profit made from the tasks executed?

(A) 150 (B) 90
(C) 120 (D) 130

Common Data for questions 28 and 29:

```
Consider the given code:
int fun (int k[ ], int n)
{
int counter = 0, max = 0;
for (int i = 0; i<n; i ++)
{
counter = 0;
for (int j = 0; j <n; j++)
{
if (k[i] = = k[j])
counter ++;
}
if (counter >max)
max = counter;
}
return max;
}
```

28. What is the task performed by the given code?

(A) Counting the number of swaps.
(B) Finding the element which appears maximum number of times in the array.
(C) Finding the element which appears minimum number of times in the array.
(D) Counting the number of comparisons.

29. What is the time complexity in executing the given code?

(A) $O(\log n)$ (B) $O(n \log n)$
(C) $O(n^2)$ (D) $O\left(n\sqrt{n}\right)$

Common Data for Questions 30 and 31:

Consider the following code:

```
void fun1(int k[ ], int n, int X)
{
for (int i = 0; i < n; i++)
{
for (j = i; j < n; j++)
{
if (k[i] + k[j] = = X)
{
printf("Items found")
return;
}
}
}
printf("Items Not found");
}
```

30. The above code performs

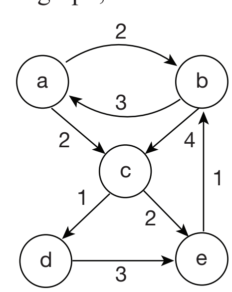
(A) The sum of 2 array elements is equal to given '*X*' value.
(B) Sum of adjacent elements whose sum is equal to given '*X*' value.
(C) The sum of adjacent elements if they are equal.
(D) The sum of adjacent elements which are equal and equal to given '*X*' value.

31. What is the time complexity of given code?

(A) $O(n \log n)$
(B) $O(n^2)$
(C) $O(n^3)$
(D) $O(\log n)$

Common Data for Questions 32 and 33:

Consider the given graph,



32. What is the eccentricity of node '*d*'?

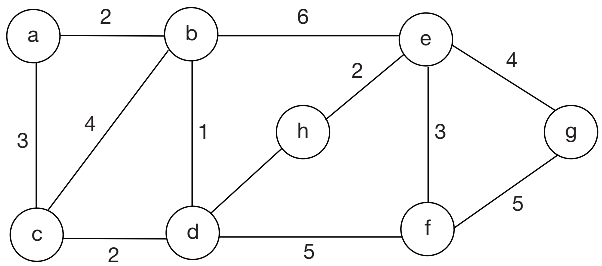
(A) 3 (B) 5
(C) 1 (D) 6

33. What is the center of given graph?

(A) Node '*a*' (B) Node '*c*'
(C) Node '*b*'
(D) Either Node '*d*' or Node '*e*'

Statement for linked Answer questions 34 and 35:

34. Consider the given graph



Which of the following can be the sequence of edges added to minimum spanning tree using "Prims Algorithm"?

(A) $(a-b), (b-d), (d-c), (d-f), (f-g), (f-e), (e-h)$
(B) $(a-b), (b-d), (d-c), (d-f), (f-e), (e-g), (e-h)$
(C) $(e-h), (e-f), (e-g), (f-d), (d-b), (b-a), (d-c)$
(D) $(e-h), (e-f), (e-g), (d-b), (f-d), (b-a), (d-c)$

35. What is the total weight of spanning tree (correct edge sequence) identified in the above question?

(A) 17 (B) 19
(C) 20 (D) 21

Answer Keys

1. C	**2.** B	**3.** B	**4.** D	**5.** C	**6.** D	**7.** B	**8.** D	**9.** 8	**10.** C
11. A	**12.** 15	**13.** B	**14.** C	**15.** B	**16.** B	**17.** A	**18.** A	**19.** C	**20.** D
21. D	**22.** D	**23.** B	**24.** C	**25.** D	**26.** C	**27.** A	**28.** B	**29.** C	**30.** A
31. B	**32.** D	**33.** C	**34.** C	**35.** B					

Hints and Explanations

1. In worst case Linear search takes $O(n)$ time, whether it is ordered list (or) unordered List. Choice (C)

2. Recurrence Relation for Binary search is $T(n) = T(n/2) + \theta(1)$. Time complexity of Binary search is $\theta(\log n)$. Choice (B)

3. Randomly given 'n' numbers are to be sorted first, which takes $O(n \log n)$ time and return the $(n/2)$th element, that is the median of given 'n' random elements. Choice (B)

4. The basic solution is to have two loops and keep track of maximum count for all different elements. If maximum count becomes greater than $n/2$ then break the loops and return the element having maximum count. If maximum count doesn't become more than $n/2$ then majority element doesn't exist.
2 loops(nested) $\Rightarrow O(n^2)$. Choice (D)

5. Number of comparisons

If 'n' is even $\frac{3n}{2} - 2$

If 'n' is odd $\frac{3n}{2} - \frac{3}{2}$. Choice (C)

6. To find First Largest element $(n - 1)$ comparisons are required, for second largest $(n - 2)$, for Third largest $(n - 3)$ and For fourth largest $(n - 4)$.

$\therefore$ Total $\Rightarrow (n - 1) + (n - 2) + (n - 3) + (n - 4)$
$\therefore$ $4n - 10 \Rightarrow 2(2n - 5)$.

Choice (D)

7. The algorithms makes $|V| - 1$ passes over the edges of the graph (E)

$(V - 1) * E$
$O(V * E)$.

Choice (B)

8. **Linear Probing:**

$h(k) = (2k + 1) \bmod 8$
$h(3) = 7 \bmod 8 = 7$
$h(8) = 17 \bmod 8 = 1$
$h(16) = 33 \bmod 8 = 1$
(collision occurred at location 1)
Search for next empty slot from the point of collision.
$h(9) = 19 \bmod 8 = 3$
$h(1) = 3 \bmod 8 = 3$ (collision)
$h(4) = 9 \bmod 8 = 1$ (collision). Choice (D)

9. str1 = A B R A C A D A B R O A

str2 = Y A B B A D A B B A D O O B A

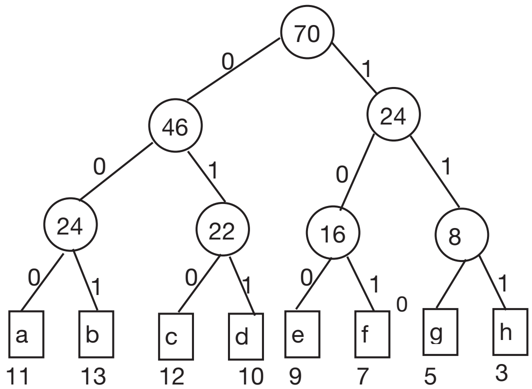
The longest common subsequence would be A B A D A B O A.
The length is '8'.

10. The string form is $a^m\, b^{2n}\, c^{3p}$, $m, n, p \geq 2$.
i.e., The strings are *aabbbbcccccc*, *aaabbbbbbcccccc-ccc*, ...
The regular expression will be
$(aa)a^*\ (bbbb)\ (bb)^*\ (cccccc)(ccc)^*$
(minimum two a's four b's, six c's will be there in the string). Choice (C)

11. $0 < i < j$
$n^j \leq c * n^i$ which is false.

Choice (A)

12. **Fixed length coding:**



If there are 8 characters, 7 merging operations would be performed. In fixed length coding each character takes same number of encoded bits, each character takes 3-bits.

'*a b f e g*', 5 characters ⇒ 5 × 3 = 15 bits.

13. In Depth First search Algorithm, First all elements (V) will be pushed onto stack and followed by (V) pop operations.

∴ Total $V * V = 2V$.

Choice (B)

14. Since the length of the given string is n, there are 'n' sub strings possible (excluding empty string) with first character. Similarly, (n – 1) substrings possible with second character and so on.

Choice (C)

15. K-Regular graph (K_{n+1}-graph) that is complete graph. Hence $O(n^3)$. Choice (B)

16.

4	2	6	4	2	6

Sorted array:

2	2	4	4	6	6

In the sorted array First repeating element is '2', but in the given array 4 is the first repeating element.

Sorted array in descending order:

6	6	4	4	2	2

In the sorted array (descending order), The first repeating element is '6'. Choice (B)

17. Greedy Approach, pick the least possible weight at each phase.

$$S \xrightarrow{2} A \xrightarrow{5} E \xrightarrow{9} G$$

⇒ 2 + 5 + 9 = 16. Choice (A)

18. Shortest distance from node 'u' to node 'v' is shown by $\delta(u, v)$ $\delta(A, G) = \min\{6 + \delta(D, G), 5 + \delta(E, G)\}$

$\delta(C, G) = \min\{1 + \delta(F, G), 6 + \delta(F, G)\}$

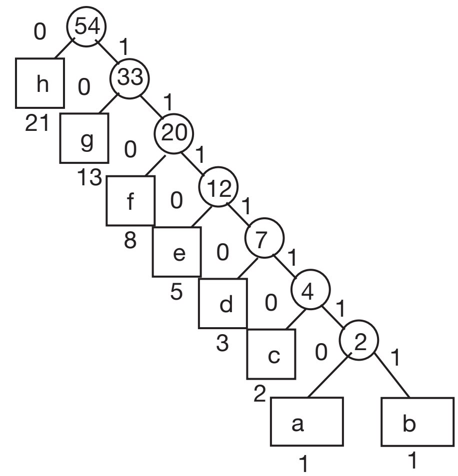
$\delta(E, G) = 9$

⇒ Back substitute the value

$\delta(E, G) = \min\{16, 4\} = 4$

$\delta(S, G) = \min\{16, 7, 6\} = 6.$ Choice (A)

19. $a – 1, b – 1, c – 2, d – 3, e – 5, f – 8, g – 13, h – 21$



Huffman codes

a – 1111110

b – 1111111

c – 111110

d – 11110

e – 1110

f – 110

g – 10

h – 0

Given code <u>110</u> <u>10</u> <u>0</u> <u>11110</u> <u>110</u>

f g h d f. Choice (C)

20. Queue

A

dequeue A, and enqueue its neighbours in lexicographic order

B	C	E

Dequeue B

C	E	G	H

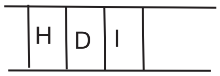
Dequeue C

E	G	H	D

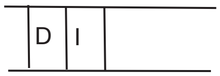
Dequeue E

G	H	D

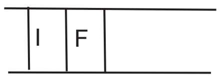
Dequeue *G*



Dequeue *H*



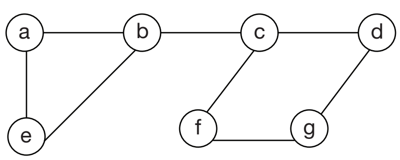
Dequeue *D*



Dequeue *I*

Dequeue *F* Choice (D)

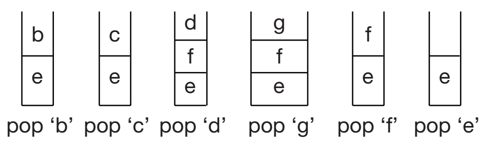
21.



Choice (A)

a, *b*, *c*, *d*, *g*, *f*, *e*

pop '*a*' and push its neighbours



popped elements ⇒ *a*, *b*, *c*, *d*, *g*, *f*, *e*
In the same way check all the options.
Choice (D) is incorrect.

Choice (D)

22. Option (A): *d*, *c*, *g*, *f*, *b*, *a*, *e*

dequeue 'd' and Enqueue its neighbours

dequeue 'c' and Enqueue its neighbours

dequeue 'g' and Enqueue its neighbours

dequeue 'f'

dequeue 'b'

dequeue 'a'

dequeue 'e'

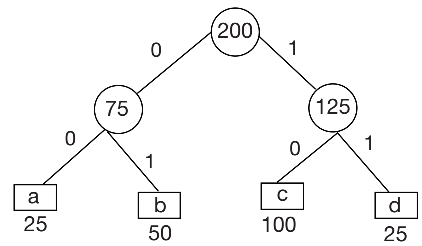
In the same way, check all the option, options (D) is incorrect. Choice (D)

23. $h(k) = k \bmod 10$

0	1	2	3	4	5	6	7	8	9
97	31	22	42	61	64	46	71	58	83

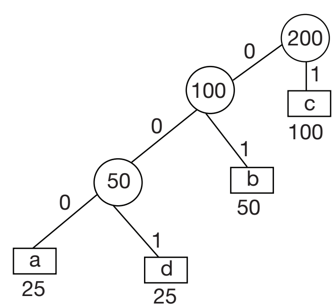
Linear Probing: when collision occurs, search for next empty slot from the place of collision, treat array as circular array. Choice (B)

24. $a - 25$, $b - 50$, $c - 100$, $d - 25$



After Encoding
$a - 00$(2 bits)
$b - 01$(2 bits)
$c - 10$(2 bits)
$d - 11$(2 bits)
Number of bits required
$= 25 \times 2 + 50 \times 2 + 100 \times 2 + 25 \times 2$
$= 50 + 100 + 200 + 50$
$= 400$ bits. Choice (C)

25. Variable Length Encoding is also called "Huffman coding"
Arrange the characters in increasing order
$a - 25$, $d - 25$, $b - 50$, $c - 100$



After Encoding:
$a - 000$ (3 bits)
$b - 01$ (2 bits)
$c - 1$ (1 bit)
$d - 001$ (3 bits)
Number of bits required
$= 25 \times 3 + 50 \times 2 + 25 \times 3 + 100 \times 1$
$= 75 + 100 + 75 + 100$
$= 350$ bits. Choice (D)

26. Arrange the tasks in decreasing order according to their profits.

T_5	T_2	T_4	T_3	T_1
4	2	1	1	2
60	50	40	30	20

T_4	T_2		T_5					

T_3 and T_1 cannot be executed because their deadlines are 1 and 2 respectively. Choice (C)

27. The executed Tasks are T_2, T_4 and T_5 and the profit made is 40 + 50 + 60 = 150. Choice (A)

28. The given code performs, For each input element, check whether there is any element with same value and for each such occurrence, increment the counter. Every time, check the current counter with the max and update it, if this value is greater than counter. Choice (B)

29. There are 2 nested loops, each loop will be executed 'n' times

$\therefore \quad n \times n = O(n^2)$. Choice (C)

30. The given code performs sum of 2 array elements which is equal to given 'X' value. Choice (A)

31. Outer loop executes '$n + 1$' times
Inner loop executes '$n - 1$' times
$\therefore O(n^2)$. Choice (B)

32. Eccentricity of a node is the maximum of minimum path from other nodes to the given node.

$$\max \begin{Bmatrix} \text{Min path } (a-d) = 3 \\ \text{Min path } (b-d) = 5 \\ \text{Min path } (c-d) = 1 \\ \text{Min path } (e-d) = 6 \end{Bmatrix}$$

Eccentricity = 6 Choice (D)

33. Center of a graph is a node with minimum eccentricity.
Eccentricity of Node 'a'

$$\max \begin{Bmatrix} \text{dist } (b-a) = 3 \\ \text{dist } (c-a) = 6 \\ \text{dis } (d-a) = 7 \\ \text{dist } (e-a) = 4 \end{Bmatrix} = 7$$

Eccentricity of Node 'b'

$$\max \begin{Bmatrix} \text{dist } (a-b) = 2 \\ \text{dist } (c-b) = 3 \\ \text{dist } (d-b) = 4 \\ \text{dist } (e-b) = 1 \end{Bmatrix} = 7$$

Eccentricity of Node 'c'

$$\max \begin{Bmatrix} \text{dist } (a-c) = 2 \\ \text{dist } (b-c) = 4 \\ \text{dist } (d-c) = 8 \\ \text{dist } (e-c) = 5 \end{Bmatrix} = 8$$

Eccentricity of Node 'd' is given in the above solution that is '6'
Eccentricity of Node 'e'

$$\max \begin{Bmatrix} \text{dist } (a-e) = 4 \\ \text{dist } (b-e) = 6 \\ \text{dist } (c-e) = 2 \\ \text{dist } (d-e) = 3 \end{Bmatrix} = 6$$

Center of a graph is min of all eccentricities min (7, 4, 8, 6, 6) = Node. Choice (C)

34. If we start Prims Algorithm with edge $(a - b)$ the sequence will be
$(a-b)$, $(b-d)$, $(d-c)$, $(d-f)$, $(f-e)$, $(e-h)$, $(e-g)$
If it starts with edge $(e-h)$ the sequence will be
$(e-h)(e-f)(e-g)$, $(f-d)$, $(d-b)$, $(b-a)$, $(d-c)$.
Choice (C)

35. For the correct sequence
$(e-h)$ $(e-f)$ $(e-g)$, $(f-d)$ $(d-b)$ $(b-a)$ $(d-c)$
2 + 3 + 4 + 5 + 1 + 2 + 2 = 19. Choice (B)

ALGORITHMS TEST 3

Number of Questions: 25 **Section Marks: 30**

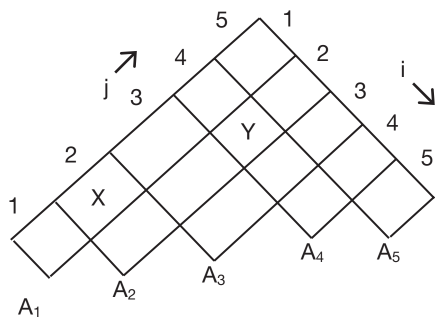
Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Given the following input 564, 816, 726, 903, 1321, 1345, 1498 and the Hash function is $h(k) = k \bmod 3$. Which of the following statements are CORRECT?
I. 564, 816, 726, 903 will hash to same Location.
II. 1321, 1345, 1498 will hash to same Location.
III. 816, 1345, 903 will hash to same Location.
(A) I and III (B) I and II
(C) II and III (D) I, II and III

2. Let M be an integer greater than 1. Which of the following represents the order of growth of the expression $\sum_{i=1}^{n} M^i$ as a function of 'n'?
(A) $\theta(n^M)$ (B) $\theta(M^{2n+1})$
(C) $\theta(M^{n \log n})$ (D) $\theta(M^n)$

Common Data For Questions 3 and 4:

To compute the Matrix product $M_1 M_2$, where M_1 has 'p' rows and 'q' columns and M_2 has 'q' rows and 'r' columns, takes time proportional to 'pqr', and result is a matrix of 'p' rows and 'r' columns. Consider the given 5 matrices, A_1, A_2, A_3, A_4 and A_5 and their dimensions are $P_0 \times P_1$, $P_1 \times P_2$, $P_2 \times P_3$, $P_3 \times P_4$, $P_4 \times P_5$, respectively. The values are $P_0 = 10$, $P_1 = 5$, $P_2 = 15$, $P_3 = 20$, $P_4 = 40$, $P_5 = 25$.



3. MATRIX-CHAIN-ORDER computes the rows from bottom to top and from left to right, The value of X (where $X = M[1, 2]$) is ________
(A) 600 (B) 750
(C) 800 (D) 900

4. The value of Y (where $Y = M[2, 4]$) is ________.
(A) 1500 (B) 5500
(C) 15000 (D) None of the above

5. Which of the following cannot be the time complexity of Quick sort algorithm, under any of the Average, Best, Worst cases?
(A) $O(n \log n)$ (B) $O(n^2)$
(C) $O(n^3)$ (D) $O(\log n)$

6. Consider the following:
I. If $f(n) = O(g(n))$ and $g(n) = O(h(n))$ then $f(n) = \Omega(h(n))$
II. The asymptotically tight upper bound for $T(n) = T(n-2) + 1$ is $O(\log n)$
Which of the following is correct?
(A) I–TRUE, II–TRUE (B) I–TRUE, II–False
(C) I–False, II–TRUE (D) I–False, II–False

7. Let
$$f(n) = 6n + 8n^2 + 200n^3,$$
$$g(n) = n^2 \log n$$
Which of the following is valid?
(A) $f(n) = O(g(n))$ (B) $f(n) = \theta(g(n))$
(C) $f(n) = \Omega(g(n))$ (D) $g(n) = \Omega(f(n))$

8. If $f(n) = n \log n$ then which of the following is FALSE?
(A) $f(n) = O(n^2 \log n)$
(B) $f(n) = \theta(n \log n)$
(C) $f(n) = \Omega(n^2)$
(D) $f(n) = \Omega(\log n * \log n)$

9. What is the average time complexity of the sequential search algorithm where the searched item is sequentially compared to each element in the list of 'n' elements?
(A) $\frac{n}{2}$ (B) $\log n$
(C) $\frac{n+1}{2}$ (D) $\frac{n-1}{2}$

10. Consider the given data:
— Let n be the number of elements
— Number of levels used in sorting: $O(\log n)$
— At each level $O(n)$ amount of work
The given data is related to:
(A) Heap sort (B) Merge sort
(C) Selection sort (D) Bubble sort

11. Consider a graph, with all distinct Edge weights, which of the following is TRUE?
(A) The shortest path is unique between every pair of vertices
(B) The maximal matching is unique
(C) The minimum spanning tree is unique
(D) All the above

12. The Hash function $h(k) = k \bmod 7$ with Linear probing is used to insert the keys 37, 38, 72, 68, 98, 11, 74 into hash table indexed (0 – 6), The location of Key 74 is ________.
(A) 1 (B) 2
(C) 3 (D) 4

13. Given an undirected graph $G = (V, E)$ and a positive integer 'K', does 'G' have 'K' vertices that form

a complete sub graph and if it does, then what is the minimum value of 'K'?

(A) 2 (B) 3
(C) 4 (D) None of the above

14. In the Build-Heap algorithm, the Heapify routine is invoked 'n' times. This indicates that Build-Heap Complexity is ______.

(A) $O(\log n)$ (B) $O(n)$
(C) $O(n \log n)$ (D) $O(n^2)$

15. Give asymptotically tight Big-O bounds for the following recurrence relations. (By using Iterative substitution method)

$$T(n) = T(n-2) + 1 \text{ if } n > 2$$
$$T(n) = 1 \quad \text{if } n \leq 2$$

(A) $O(n \log n)$ (B) $O(n)$
(C) $O(n^2)$ (D) $O(\log n)$

16. Consider the given code:

```
public static int f2(int n){
int x = 0;
for (int i= 0; i < n; i++)
for (int j = 0; j < i * i; j++)
x++;
return x;
}
```

What is the order of growth of the above code?

(A) $O(\log n)$ (B) $O(n^2)$
(C) $O(n^3)$ (D) $O(2^n)$

17. Consider the following:

I. $(3n)! = O(n!^3)$ II. $\log(n!) = \theta(n \log n)$

Which of the following is correct?

(A) I–False, II–False (B) I–False, II–TRUE
(C) I–TRUE, II–False (D) I–TRUE, II–TRUE

18. The Floyd-Warshall all pairs shortest path algorithm for finding the shortest distances between nodes in a graph is an example of:

(A) An iterative based divide - and - conquer
(B) A Dynamic programming formulation
(C) A greedy algorithm
(D) A recursive based divide - and - conquer

19. Which of the following is not having $O(n^2)$ complexity?

(A) $n + 2000n$ (B) $n^{1.999}$
(C) $10^6 n + 2^6 n$ (D) $\frac{n^3}{\sqrt{n}}$

20. Consider the given two strings str1 and str2.
Let str1 = < A B R A C A D A B R O A >
str2 = < Y A B B A D A B B A D O O B A >
Then the length of longest common subsequence would be ___________.

(A) 5 (B) 6
(C) 7 (D) 8

21. What is the computational complexity of the following piece of code:

```
for (i = n; i > 0; i/= 2){
for (int j = 1; j < n; j * = 2){
for (int k = 0; k < n; k + = 2){
      sum + = (i + j * k);
      }
   }
}
```

(A) $O(n^3)$
(B) $O(n^2 \log n)$
(C) $O(\log n * \log n * \log n)$
(D) $O(n * \log n * \log n)$

22. Consider the modified binary search algorithm so that it splits the input not into 2 sets of sizes equal sizes, but into three sets of sizes approximately one-third. What is the recurrence for this ternary search algorithm?

(A) $T(n) = T\left(\frac{n}{2}\right) + T(n-2) + C$

(B) $T(n) = T\left(\frac{n}{3}\right) + C$

(C) $T(n) = T\left(\frac{3n}{4}\right) + T\left(\frac{n}{4}\right) + C$

(D) $T(n) = T\left(\frac{n}{3}\right) + \log n$

23. Sort the following growth rate classes in increasing order of time complexity:
Exponential, quadratic, logarithmic, cubic, and factorial.

(A) Logarithmic, quadratic, cubic, exponential, factorial
(B) Logarithmic, quadratic, cubic, factorial, exponential
(C) Quadratic, cubic, logarithmic, exponential, factorial
(D) Quadratic, cubic, logarithmic, factorial, exponential

24. Determine if 'x' is present in an array of n-elements:

```
for i = 0 to n
if (a[i] = x) return TRUE
else
return false
```

What is the worst case, best case time complexities and space complexity respectively?

(A) $O(n)$, $O(1)$, $O(n)$
(B) $O(n)$, $O(1)$, $O(1)$
(C) $O(n)$, $O(\log n)$, $O(1)$
(D) $O(\log n)$, $O(\log n)$, $O(n)$

25. What is the space complexity of following sorting algorithms respectively?

I. Quick sort II. Merge sort
III. Selection sort IV. Insertion sort

(A) $O(n)$, $O(n)$, $O(1)$, $O(1)$
(B) $O(1)$, $O(n)$, $O(1)$, $O(n)$
(C) $O(1)$, $O(n)$, $O(1)$, $O(1)$
(D) $O(1)$, $O(n)$, $O(n)$, $O(1)$

Answer Keys

21. D	22. B	23. A	24. B	25. C					

Hints and Explanations

1. $h(k) = k \bmod 3$

564 mod 3 = 0
816 mod 3 = 0
726 mod 3 = 0
903 mod 3 = 0
1321 mod 3 = 1
1345 mod 3 = 1
1498 mod 3 = 1

564, 816, 726, 903 will hash to same location,
1321, 1345, 1498 will hash to same location.
Statement III is not TRUE. Choice (B)

2. Let M value be '3'

$$\sum_{i=1}^{n} 3^i = 3^1 + 3^2 + 3^3 \ldots + 3^n$$

The sequence is in Geometric Progression.

First term $= 3 = a$

$$r = \frac{3^2}{3} = 3$$

As $r > 1 \Rightarrow \text{sum} = a\frac{(r^n - 1)}{r - 1}$

$$3 \cdot \frac{(3^n - 1)}{3 - 1} = \frac{3(3^n - 1)}{2}$$

$$= \frac{3.3^n - 3 * 1}{2} = \frac{3^{n+1} - 3^1}{2}$$

$= 3^{n+1} \Rightarrow 3^n$ (Ignore constants in Asymptotic Notations)

$\therefore$ $\theta(M^n)$ is the order of growth of given expression. Choice (D)

3. Computing the matrix product $A_{i....k}\, A_{k+1....j}$ takes $P_{i...1}\, P_k\, P_j$ scalar multiplications.

$M[i, j]$

$$= \begin{cases} 0 & \text{if } i = j \\ \min\limits_{i \le k < j} \{M[i,k] + M[k+1, j] + P_{i-1} P_k P_j, & \text{if } i < j\} \end{cases}$$

$X = M[1, 2]$
$i = 1, j = 2$
$\therefore$ $k = 1$ $(\because i \le k < j)$
$P_0 = 10, P_1 = 5, P_2 = 15, P_3 = 20,$
$P_4 = 40, P_5 = 25$
$M[1, 1] = 0$
$M[2, 2] = 0$
$M[3, 3] = 0$
$M[4, 4] = 0$
$M[5, 5] = 0$

$$M[1, 2] = \min_{i \le k < j} [M[i, k] + M[k+1, j] + P_{i-1} P_k P_j$$

$$K = 1 \Rightarrow M[1, 2] = M[1, 1] + M[2, 2] + P_0\, P_1\, P_2$$

$0 + 0 + 10 \times 5 \times 15$
$= 750$ Choice (B)

4. $M[2, 4] \to$ The possible values for 'K' are 2, 3.

(1) $\underset{k=2}{M[2,4]} = M[2, 2] + M[3, 4] + P_1\, P_2\, P_4$

(2) $\underset{k=3}{M[2,4]} = M[2, 3] + M[4, 4] + P_1\, P_3\, P_4$

We need to get the values of $M[3, 4]$ and $M[2, 3]$

$\underset{k=3}{M[3,4]} = M[3, 3] + M[4, 4] + P_2\, P_3\, P_4$

$0 + 0 + 15 \times 20 \times 40 = 12000$

$\underset{k=2}{M[2,3]} = M[2, 2] + M[3, 3] + P_1\, P_2\, P_3$
$= 0 + 0 + 5 \times 15 \times 20$
$= 1500$

Choose min of (1) and (2)

$\underset{k=2}{M[2,4]} = M[2, 2] + M[3, 4] + P_1\, P_2\, P_4$

$0 + 12000 + 5 \times 15 \times 40$
$= 12000 + 3000 = 15000$

$\underset{k=3}{M[2,4]} = M[2, 3] + M[4, 4] + P_1\, P_3\, P_4$
$= 1500 + 0 + 5 \times 20 \times 40$
$= 1500 + 4000 = 5500$

$\therefore$ $M[2, 4] = \min\{15000, 5500\} = 5500$ Choice (B)

5. Average and Best case time complexities are $O(n \log n)$ and $O(n \log n)$

Worst case time complexity is $O(n^2)$

Since $(n \log n)$ and n^2 are less than n^3, $O(n^3)$ is also valid. Choice (D)

6. I. $f(n) = O(g(n))$ and $g(n) = O(h(n))$ then $f(n) = \Omega(h(n))$

Lets assume

$f(n) = n$
$g(n) = n^2$
$h(n) = n^3$
$f(n) \le g(n)$
$\Rightarrow$ $n \le n^2$
$g(n) \le h(n) \Rightarrow n^2 \le n^3$
Then $f(n) \ge h(n)$
$\Rightarrow$ $n \ge n^3$ (false)

II. $T(n) = T(n - 2) + 1$

Gives $O(n)$ time complexity (False) Choice (D)

7. $f(n) = 6n + 8n^2 + 200n^3 \Rightarrow n^3$

$g(n) = n^2 \log n$

Option (A):

$n^3 \leq c * n^2 \log n$ (false)

Option (B):

$n^3 = c * n^2 \log n$ (false)

Option (C):

$n^3 \geq c * n^2 \log n$ (TRUE) Choice (C)

8. Option (A):

$n \log n \leq c * n^2 \log n$ (TRUE)

Option (B):

$n \log n = c * n \log n$ (TRUE)

Option (C):

$n \log n \geq c * n^2$ (False) Choice (C)

9. In an average case, the probability that 'X' is in the K^{th} array slot is $1/n$, hence the average number of comparisons is

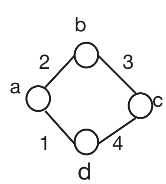
$$\sum_{i=1}^{n}\left(K \times \frac{1}{n}\right) = \frac{1}{n} \times \sum_{k=1}^{n} K$$

$$= \frac{1}{n} * \frac{n(n+1)}{2} = \frac{n+1}{2}$$ Choice (C)

10. In the worst, average, best cases, merge sort procedure will have $O(\log n)$ levels.

In each level $O(n)$ work is required. Choice (B)

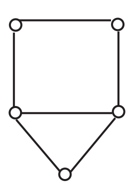
11. Option (A):



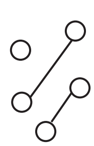
∴ There are 2 shortest paths From 'a' to 'c'

1. $a - b - c$
2. $a - d - c$

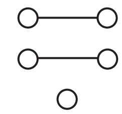
Option (B):



Maximal matching 1



Maximal matching 2



Option (C)

For any graph, there will be unique spanning tree.

Choice (C)

12. Hash function $h(k) = k \bmod 7$

Given elements are: 37, 38, 72, 68, 98, 11, 74

37 mod 7 = 2

38 mod 7 = 3

72 mod 7 = 2

68 mod 7 = 5

98 mod 7 = 0

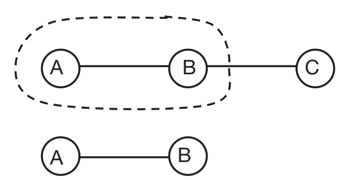
11 mod 7 = 4

74 mod 7 = 4

98	0
74	1
37	2
38	3
72	4
68	5
11	6

Choice (A)

13.



It is a complete sub graph, with $K = 2$. Choice (A)

14. Heapify routine takes $O(\log n)$ time, if it is invoked 'n' times then Build Heap takes $n * \log n \Rightarrow O(n \log n)$.

Choice (D)

15. Given Recurrence Relation:

$T(n) = T(n - 2) + 1$

Assume $n = 16$

$T(16) = T(14) + 1$

$T(14) = T(12) + 1$

$T(12) = T(10) + 1$

$T(10) = T(8) + 1$

$T(8) = T(6) + 1$

$T(6) = T(4) + 1$

$T(4) = T(2) + 1$

$T(2) = 1$

$T(4) = 2$

$T(6) = 3$

$T(8) = 4$

$T(10) = 5$

$T(12) = 6$

$T(14) = 7$

$$T(16) = 8$$

$$\Rightarrow \frac{n}{2} \Rightarrow O\left(\frac{n}{2}\right) \Rightarrow O(n)$$ Choice (B)

16. Each iteration of the inner loop is quadratic in the outer loop variable. The simplest way to do this is to realize we are just summing Si^2, which will just be $O(n^3)$, if we use the integration trick. Choice (C)

17. Let us assume some value for n

$n = 5$

I. $(3 \times 5)! = 15! =$ very large number

$(5!)^3 = 120^3 = 1728000$

$(3n)! < O(n!^3)$

I–false

II. $\log(n!) = \theta(n \log n)$

lets take $n = 8$

$\log(n!) = \log(8!) = \log(40320) = 15.299$

$n \log n = 24$

$\log(n!) < (n \log n)$

II–false Choice (A)

18. The Floyd-warshall all pairs shortest path algorithm in a graph is an example of a dynamic programming formulation.

Choice (B)

19. Option (A)

$n + 2000n \leq c * n^2$

$\Rightarrow \quad n \leq c * n^2$ (TRUE)

Option (B)

$n^{1.999} \leq c * n^2$ (TRUE)

Option (C)

$10^6 n + 2^6 n \leq c * n^2$

$n \leq c * n^2$ (TRUE)

Option (D)

$\frac{n^3}{\sqrt{n}} \leq c * n^2$ (False)

$n^{2.5} \leq c * n^2$(False)

$\therefore$ for a very large value of 'n'

Choice (D)

20. str1 = A B R A C A D A B R O A

str2 = Y A B B A D A B B A D O O B A

The longest common subsequence would be A B A D A B O A.

The length is '8'. Choice (D)

21. In the outer for loop, the variable 'i' keeps halving, so it goes a round ($\log n$) times. For each 'i' next loop goes round also ($\log n$) times, because of doubling the variable j. The inner most loop by 'k' goes round $\frac{n}{2}$ times. Loops are nested, so the bounds may be multiplied to give that the algorithm is $O(n * \log n * \log n)$

Choice (D)

22. By analogy, we divide the elements instead of 2 subsets, we divide them into three subsets.

$$\therefore \quad T(n) = T\left(\frac{n}{3}\right) + c$$ Choice (B)

23. logarithmic $\rightarrow \log n$

cubic $\rightarrow n^3$

quadratic $\rightarrow n^2$

Exponential $\rightarrow 2^n$

Factorial $\rightarrow n!$

$\log n < n^2 < n^3 < 2^n < n!$

Logarithmic, quadratic, cubic, exponential, Factorial.

Choice (A)

24. The procedure given in problem performs linear search,

Worst case $\Rightarrow O(n)$

Best case $\Rightarrow O(1)$

We do not require extra space to search for an element in an array, so space complexity is $O(1)$. Choice (B)

25. Quick sort, selection sort, insertion sort are 'In-place' algorithms means they do not take extra space.

$\therefore O(1), O(1), O(1)$

Merge sort is Not In-Place algorithm.

It needs extra space

$\therefore O(n)$. Choice (C)

Algorithms Test 4

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Suppose 'G' is an undirected graph, Then which of the following is TRUE?

I. If G is a tree, there is a unique path between any 2 vertices in G.

II. If $G = (V, E)$ is connected and $E = V - 1$, then G is a tree.

III. Deleting an edge from a cycle cannot disconnect a graph.

(A) Only II (B) Only III
(C) Only I, II (D) I, II and III

2. Consider an array with 'n' values, to return the maximum sum of 3 values in an array. What is the time complexity of performing this task?

(A) $O(n)$ (B) $O(n^2 \log n)$
(C) $O(n^2)$ (D) $O(\log n)$

3. What is the length of longest increasing subsequence of '6, 4, 5, 2, 7, 11, 8, 12, 13, 9, 10'?

(A) 2 (B) 3
(C) 4 (D) 5

4. Consider 2 sequences, S = gacggattag, and X = gatcggaatag. What is the length of Longest common subsequence?

(A) 7 (B) 8
(C) 9 (D) 11

5. How does the key in a node compared to the keys of its children in

I. Binary search tree

II. A Max HEAP

P. node. key > node.left.key, node.right.key

Q. node.left.key < node.key < node.right.key

Which of the following is correct?

(A) I–P, II–Q (B) I–P, II–P
(C) I–Q, II–P (D) I–Q, II–Q

6. A hash table has 11 slots, uses the hash function $h(k) = k$ mod 11 and collisions are resolved by separate chaining, what is the minimum chain length in the hash table, after inserting these elements:

3, 43, 8, 11, 14, 25

(A) 0 (B) 1
(C) 2 (D) 3

7. Which priority queue implementations, with N elements allow for new entries to be inserted in $O(1)$ time?

(A) Sorted array (B) MAX HEAP
(C) MIN HEAP (D) Unsorted array

8. In order to search for an element in a dynamic set, which of the following techniques is the asymptotically most time efficient in the worst case for the search operation?

(A) Store the element in an unsorted array and apply linear search.
(B) Store the element in a hash table and use hashing.
(C) Store the element in a sorted array and apply binary search.
(D) All the above

9. Which of the following problems have solutions (algorithms) that run in $\theta(n)$ time in the worst case?

(A) Finding the median of 'n' integers
(B) Finding the sum of 'n' integers
(C) Finding the largest of 'n' integers
(D) All the above

10. Consider the following: (Here $h(\ )$ is a hash function).

I. $h(k_1) = h(k_2)$ even for $k_1 \neq k_2$

II. $h(k_1) \neq h(k_2)$ for $k_1 < k_2$ always

III. $h(k_1) = h(k_2)$ for $k_1 > k_2$ always

Which of the following is TRUE?

(A) I only (B) I and II
(C) II and III (D) I, II and III

11. Let 'OPT' be an optimal solution and 'x' the solution we found.

If OPT equals x then we are done otherwise, we can find another optimal solution that 'agrees more with x' which of the following algorithm has in first attempt 'OPT = x'?

(A) Fractional knapsack
(B) Travelling sales person problem
(C) Kruskals algorithm
(D) None of the above

12. Match the following algorithm with its time complexity.

I	Dijkstras algorithm	P.	$O(E + V) \log V$
II	Prims algorithm	Q.	$O(E + V)$
III	Breadth first search		
IV	Depth first search		

(A) I–P, II–P, III–P, IV–Q
(B) I–P, II–P, III–Q, IV–Q
(C) I–Q, II–Q, III–P, IV–P
(D) I–Q, II–P, III–P, IV–Q

13. The distance matrix of a graph with vertices A, B, C, and D is given below:

$$\begin{array}{c} \\ A \\ B \\ C \\ D \end{array} \begin{array}{c} \begin{array}{cccc} A & B & C & D \end{array} \\ \begin{bmatrix} 0 & 1 & \infty & \infty \\ \infty & 0 & 2 & 4 \\ 3 & \infty & 0 & 1 \\ 1 & \infty & \infty & 0 \end{bmatrix} \end{array}$$

The shortest path from B to D consists of edge(s) ________.

(A) BC and CD
(B) BD

(C) *AB* and *CD*
(D) There is no shortest path

14. Match the following:

	Sorting algorithm		Programming paradigm
I	Insertion sort	P	Dynamic programming
II	Selection sort	Q	Divide and conquer
III	Merge sort	R	Greedy algorithm
IV	Quick sort	S	Back tracking

(A) I–P, II–R, III–Q, IV–Q
(B) I–P, II–R, III–Q, IV–S
(C) I–R, II–P, III–Q, IV–Q
(D) I–R, II–P, III–Q, IV–S

15. Given a set of objects with (Weight, Profit) pair, and a knapsack of limited weight capacity (M), find a subset of objects for the knapsack to maximize total profit 'p'.
Objects (Weight, Profit)
$$= \{(3, 2), (4, 3), (10, 21), (6, 4)\}$$
$$M = 9 \text{ (using 0/1 knapsack)?}$$
(A) 5 (B) 6
(C) 21 (D) 7

16. There are multiple ways to order the multiplication of 4 matrices A, B, C, D: $(A(BC)D)$, $A(B(CD))$, $(AB)(CD)$, $((AB)C)D$, $A((BC)D)$.
Efficiency depends on number of scalar multiplications, in the case of $(A(BC))D$ it is
$$1 \times 4 \times 3 + 5 \times 1 \times 3 + 5 \times 3 \times 6 = 117$$
In the case of $(A(B(CD)))$, it is
$$4 \times 3 \times 6 + 1 \times 4 \times 6 + 5 \times 1 \times 6 = 126$$
What are the dimensions of A, B, C, D respectively?
(A) 5×1, 1×4, 4×6, 6×3
(B) 4×3, 3×5, 5×6, 6×1
(C) 5×1, 1×4, 4×3, 3×6
(D) 1×4, 4×3, 3×5, 5×6

17. Suppose that the symbols a, b, c, d, e occur with frequencies $\frac{1}{36}, \frac{1}{36}, \frac{1}{12}, \frac{1}{9}, \frac{5}{36}$ then what is the Huffman Encoding of the alphabets a, b, c respectively?
(A) 1101, 111, 1101 (B) 1100, 1101, 111
(C) 1100, 10, 0 (D) 1101, 1100, 111

18. We are given 'n' positive integers $a_1, \ldots, a_n$. The goal is to select a subset of the numbers with maximal sum such that no three consecutive numbers are selected.
Sequence is '7 5 6 3 8 12 9 13 14 10 11'
What is the maximal sum?
(A) 66 (B) 68
(C) 69 (D) 72

19. Consider the coin change problem with coin values 1, 5, 6, Does the greedy algorithm always find an Optional solution?
(A) No, for even numbers
(B) Yes, for odd numbers
(C) Yes, for even numbers
(D) No

20. If a data structure supports an operation 'foo' such that a sequence of 'n' foo operations take $\theta(n \log n)$ time to perform in the worst case, then the amortized time of a 'foo' operation is θ(____)
(A) $\theta(n)$ (B) $\theta(\log n)$
(C) $\theta(\log n)$ (D) $\theta(n)$

21. Consider the following statements:
I. Computing the median of 'n' elements takes $\Omega(n \log n)$ time for any algorithm working in the comparison based model.
II. Let 'T' be a minimum spanning tree of G, then for any pair of vertices 'a' and 'b' the shortest path from 'a' to 'b' in G is the path from 'a' to 'b' in T.
Which of the following is CORRECT?
(A) I–TRUE, II–False (B) I–TRUE, II–TRUE
(C) I–False, II–TRUE (D) I–False, II–False

22. Below are the contents of an array of some sorting algorithm sorting it.
Identify the algorithm from given steps:
12 39 2 94 23 77 52 9
12 $\underline{39}$ 2 94 23 77 52 9
$\underline{2}$ 12 39 94 23 77 52 9
2 12 39 $\underline{94}$ 23 77 52 9
2 12 $\underline{23}$ 39 94 77 52 9
2 12 23 39 $\underline{77}$ 94 52 9
2 12 23 39 $\underline{52}$ 77 94 9
2 $\underline{9}$ 12 23 39 52 77 94
(A) Quick sort (B) Selection sort
(C) Insertion sort (D) Bubble sort

23. Below are the contents of an array of some sorting algorithm sorting it.
Identify the algorithm from given steps:
12 39 02 94 23 77 52 09
1$\underline{2}$ 0$\underline{2}$ 5$\underline{2}$ 2$\underline{3}$ 9$\underline{4}$ 7$\underline{7}$ 3$\underline{9}$ 0$\underline{9}$
$\underline{0}$2 $\underline{0}$9 $\underline{1}$2 $\underline{2}$3 $\underline{3}$9 $\underline{5}$2 $\underline{7}$7 $\underline{9}$4
(A) Selection sort (B) Heap sort
(C) Bubble sort (D) Radix sort

24. Suppose that we have possible keys $[0, 1, \ldots, n^2 - 1]$ for a hash table of size 'n', what is the greatest number of distinct keys the table can hold with each of the following separate chaining, Linear probing, Quadratic probing, collision resolution strategies respectively?
(A) n, n, n^2 (B) n^2, n, n^2
(C) n^2, n, n (D) n^2, n^2, n^2

25. Given these 2 states of an array, the second one results from the first pass of which sorting algorithm?

14	5	21	4	16	31	17	8	11

5	14	4	16	21	17	8	11	31

(A) Insertion sort (B) Selection sort
(C) Merge sort (D) Bubble sort

Answer Keys

1. D	**2.** C	**3.** B	**4.** C	**5.** C	**6.** A	**7.** D	**8.** B	**9.** D	**10.** A
11. C	**12.** B	**13.** A	**14.** A	**15.** B	**16.** C	**17.** B	**18.** C	**19.** D	**20.** C
21. D	**22.** C	**23.** D	**24.** C	**25.** D					

Hints and Explanations

1. All the statements are TRUE. Choice (D)

2. First sort the given array with 'n' values. In the worst case sorting takes $O(n^2)$ time.
Last '3' values in the array can be added in constant time. Choice (C)

3. 6 4 5 $\boxed{2\ 7\ 11}$ $\boxed{8\ 12\ 13}$ 9 10
Longest increasing subsequence length is 3
(i) 2 7 11 (ii) 8 12 13. Choice (B)

4.
S = <u>gac</u> <u>gga</u> t <u>tag</u>
X = <u>ga</u> t c <u>gga</u> a <u>tag</u>
LCS = {g a c g g a t a g}
Length = 9. Choice (C)

5. **Binary search tree:**
node · left. key < node. key < node × right. key
max heap:
node. key > node. left . key, node. right. key.
Choice (C)

6. Hash function is $h(k) = k \bmod 11$
3 mod 11 = 3
43 mod 11 = 10
8 mod 11 = 8
11 mod 11 = 0
14 mod 11 = 3
25 mod 11 = 3
The minimum chain length is '0', from the hash values it is clear that, the chains with slot numbers 1, 2, 4, 5, 6, 7, 9 are empty.
We do not need to construct a hash table to check the chain lengths. Choice (A)

7. To insert an element in a sorted array we need to check for the correct position of the element. In the worst case it will take 'n' comparisons.
In max-heap and min-heap, we need (log n) time to insert an element.
In unsorted array simply keep the element at the end of the array. Choice (D)

8. Searching an element in a hash table using hashing takes constant time usually, it is the efficient search method, but its implementation depends on hash function, table size etc. Choice (B)

9.
- Median of 'n' integers can be finded by traversing the entire list. It takes θ(n) time.
- Sum of 'n' integers take $(n - 1)$ computation which requires $\theta(n)$ time.
- For finding largest of 'n' number it requires $(n - 1)$ comparisions which requires $\theta(n)$ time.

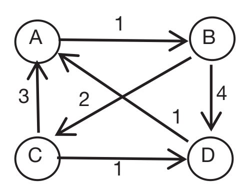
Choice (D)

10. Suppose $h(k) = k \bmod 5$
$k_1 = 10, k_2 = 15$
I. I–TRUE
II. $k_1 = 6, k_2 = 11$
6 mod 5 = 1, 11 mod 5 = 1
II–False
III. $k_1 = 16, k_2 = 14$
16 mod 5 = 1, 14 mod 5 = 4
III–false. Choice (A)

11. Kruskals algorithm is used to construct a minimum spanning tree, in the first attempt itself we will get optimal solution. Choice (C)

12. Dijkstras Algorithm and prims algorithm implementation is similar.
Time complexity is $O(E + V) \log V$
Depth first search and Breadth first search has same time complexity $O(E + V)$. Choice (B)

13. From the given matrix, the graph is drawn



Shortest path from B to $D \Rightarrow = (\overline{BC} - \overline{CD})$
$= 2 + 1 = 3$. Choice (A)

14.
- Insertion sort is a quadratic time sorting algorithm. It is an example of dynamic programming.
- Selection sort is a quadratic time sorting algorithm, It is an example of greedy algorithm.
- Merge sort and Quick sort are examples of Divide and conquer approach. Choice (A)

15. $M = 9$
(i) Weight $= 3 + 4 \le 9$
Profit $= 2 + 3 = 5$
(ii) Weight $= 3 + 6 \le 9$
Profit $= 2 + 4 = 6$. Choice (B)

16. $(A\ (B\ (CD))) = 4 \times 3 \times 6 + 1 \times 4 \times 6 + 5 \times 1 \times 6$
First $(CD) = 4 \times 3 \times 6$
$[C]_{4\times3} \times [D]_{3\times6} = [\text{Res } 1]_{4\times6}$
$(B \text{ Res } 1) = 1 \times 4 \times 6$
$[B]_{1\times4}\ [\text{Res } 1]_{4\times6} = [\text{Res } 2]_{1\times6}$
$(A \text{ Res } 2) = 5 \times 1 \times 6$
$[A]_{5\times1}\ [\text{Res } 2]_{1\times6} = [\text{Res } 3]_{5\times6}$
$\therefore \quad A = 5 \times 1,$

$B = 1 \times 4,$
$C = 4 \times 3,$
$D = 3 \times 6.$ Choice (C)

17. $a = \frac{1}{36} = 0.02$

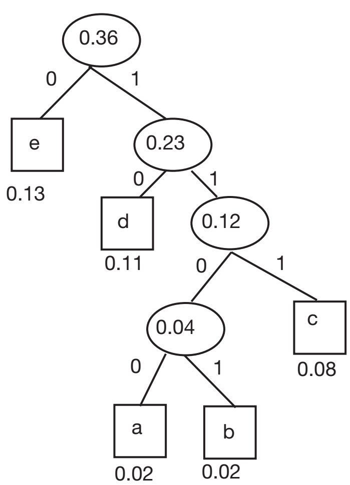
$b = \frac{1}{36} = 0.02$

$c = \frac{1}{12} = 0.08$

$d = \frac{1}{9} = 0.11$

$e = \frac{5}{36} = 0.13$

Huffman tree:



Huffman codes
$a = 1100$, $b = 1101$, $c = 111$, $d = 10$, $e = 0$. Choice (B)

18. $\boxed{7\ 5}$ 6 $\boxed{3\ 8}$ 12 $\boxed{9\ 13}$ 14 $\boxed{10\ 11}$
$12 + 11 + 22 + 21 = 66$
7 $\boxed{5\ 6}$ 3 $\boxed{8\ 12}$ 9 $\boxed{13\ 14}$ 10 $\boxed{11}$
$11 + 20 + 27 + 11 = 69.$ Choice (C)

19. Coin values 1, 5, 6.
Value = 20

(i) $\frac{\text{Greedy Algorithm}}{6+6+6+1+1}$

$\Rightarrow$ 5 coins

(ii) $\frac{\text{Brute-Force}}{5+5+5+5}$

$\Rightarrow$ 4 coins
Value = 21

(iii) $\frac{\text{Greedy Algorithm}}{6+6+6+1+1+1}$

$\Rightarrow$ 6 coins

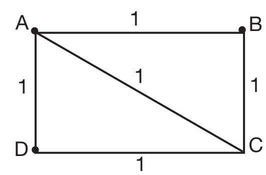
(iv) $\frac{\text{Brute Force}}{5+5+5+5+1}$

$\Rightarrow$ 5 coins. Choice (D)

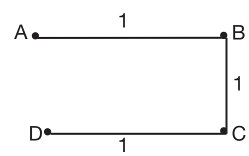
20. Amortized time is $\theta(\log n)$
Worst case time is $\theta(n \log n)$. Choice (C)

21.
- Computing a median of 'n' elements takes $\theta(n)$ time as it has to traverse 'n' elements.
- The shortest path between 2 vertices need not be same in the Minimum spanning tree and in graph.

Consider following graph G



The MST for the above graph 'G' is



The shortest path from A to C is 1 in graph 'G' where as, it is 2 in MST. Choice (D)

22. $\boxed{12\ 39}$ 2 94 23 77 52 9

$\boxed{2\ 12\ 39}$ 94 23 77 52 9

$\boxed{2\ 12\ 39\ 94}$ 23 77 52 9

$\boxed{2\ 12\ 23\ 39\ 94}$ 77 52 9

$\boxed{2\ 12\ 23\ 39\ 77}$ 94 52 9

$\boxed{2\ 12\ 23\ 39\ 77}$ 52 9

2 12 23 39 52 77 94 9

$\therefore$ 2 9 12 23 39 52 77 94

$\therefore$ Insertion sort. Choice (C)

23. Given elements 12 39 02 94 23 77 52 09
First sort elements based on least significant digit

12 02 52 23 94 77 39 09.

Sort the above elements based on second least significant digit.

02 09 12 23 39 52 77 94

$\therefore$ The above sorting algorithm is 'Radix–Sort'.
Choice (D)

24. The available elements are $[0, 1, 2, ..., n^2 - 1]$
There are n^2 elements.
Separate chaining has unlimited space, it can save all the n^2 elements.

Linear probing:
It will have 'n' slots, so maximum we can store 'n' values.
Quadratic probing:
Like linear probing, it will also have 'n' slots.
We can store only 'n' values.

Choice (C)

25. Bubble sort, compares adjacent elements, if not in order swaps them.

14	5	21	4	16	31	17	8	11

5 14 21 4 16 31 17 8 11

5 14 4 21 16 31 17 8 11

5 14 4 16 21 31 17 8 11

5 14 4 16 21 17 31 8 11

5 14 4 16 21 17 8 31 11

5 14 4 16 21 17 8 11 31.

Choice (D)

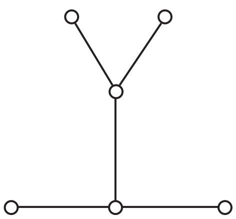
Algorithms Test 5

Number of Questions: 25 **Section Marks: 30**

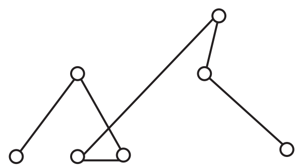
Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Which of the following is NOT a tree?

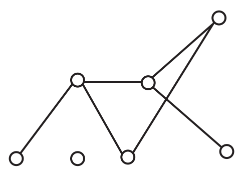
(A)



(B)



(C)



(D) None of the above

2. What is the number of vertices in a tree with 57 edges?

(A) 58 (B) $2^6 - 4$
(C) 56 (D) 57

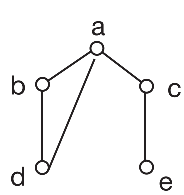
3. Consider 2 graphs G_1 and G_2:

I. G_1 is connected and every edge is a bridge.
II. In G_2 for any pair of vertices in the graph there is one and only one path joining them.

Which of the following is TRUE?

(A) G_1 is a tree but G_2 is not a tree
(B) G_1 is not a tree but G_2 is a tree
(C) Both G_1 and G_2 are trees
(D) Both G_1 and G_2 are not trees

4. How many spanning trees does the following graph contain, (Assume that all edges have same weight)?



(A) 2 (B) 3
(C) 4 (D) 5

5. Suppose we have a graph where each edge value appears atmost twice, then what will be the number (atmost) of minimum spanning Trees of this graph?

(A) 2 (B) 3
(C) 4 (D) 6

6. If we run Dijkstra's algorithm starting from 'S' to find shortest path 'T', consider the following statements:

I. Dijkstra's algorithm returns shortest path with minimum total weight.
II. Dijkstra's algorithm returns shortest path, with minimum number of edges.

Which of the following is TRUE?

(A) I only (B) II only
(C) Both I and II (D) None of the above

7. The reason for using Bellman-Ford algorithm for finding the shortest path between 2 vertices in a graph, when Dijkstras algorithm does the same thing:

I. Bellman-Ford Algorithm is faster than Dijkstra's Algorithm.
II. Bellman-Ford Algorithm works on any directed graph, with negative weights also.

Which of the following is TRUE?

(A) I only (B) II only
(C) Both I and II (D) None of these

8. Consider the following statements:

I. By applying Breadth First search, on a tree with all edges having equal weight; finds minimum distance from root to any node.
II. Use of greedy algorithm to solve the knapsack with fractions is optimal.

Which of the following is TRUE?

(A) I only (B) II only
(C) Both I and II (D) None of the above

9. Consider the set of keys {1, 4, 5, 10, 16, 17, 21}, Draw a binary search tree with height '2,' Then what values will appear at internal nodes? [height of root node is '0']

(A) 10, 5, 16 (B) 10, 4, 17
(C) 4, 17, 21 (D) 5, 10, 17

10. Consider the set of keys {2, 5, 6, 11, 17, 18, 22}, Draw a binary search tree with height '6', then, what will be the child node values (height of root node is 0).

(A) 2 (B) 22
(C) Either 2 or 22 (D) None of the above

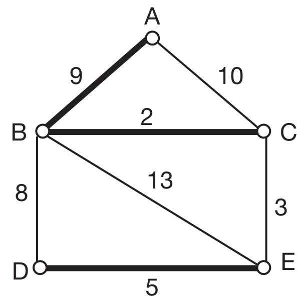
11. The following is a directed graph

$G = (V, E)$:
$V = \{a, b, c, d, e, f, g\}$
$E = \{(a, b), (c, a), (b, c), (c, d), (d, e), (e, f), (e, g), (f, g), (d, g)\}$

Identify the correct strongly connected components, which of the following is TRUE?

(A) There are 3 strongly connected components.
(B) There are 4 strongly connected components.
(C) There are 5 strongly connected components.
(D) None of the above

12. Consider the given graph, with some edges in bold:



The bold edges given in the above graph cannot form a spanning Tree because

(A) The bold edges are not connected
(B) The bold edges are not least weight edges
(C) The kruskals algorithm is not implemented on the above graph.
(D) Both (A) and (B)

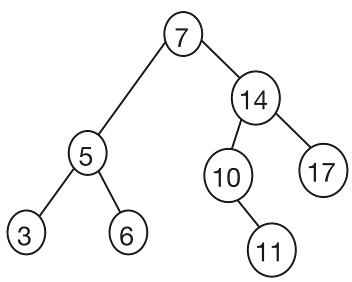
13. Consider the given statements:

I. A digraph is a graph with exactly 2 vertices.
II. A spanning tree of a graph must contain atleast $\frac{n}{2}$ edges always.
III. The sorted edges algorithm for solving the travelling salesman problem always gives optimal result.

Which of the following is TRUE?

(A) I and II (B) II and III
(C) I and III (D) Only II

14. Consider the given AVL-tree,



If the element with value '12' is inserted into above AVL tree, How many rotations are required to balance the tree?

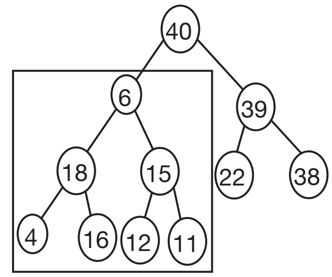
(A) 0 (B) 1
(C) 2 (D) 3

15. In which order, the element must be inserted into an AVL tree, so that, no single Rotation is required, for the given

Elements = {1, 2, 3, 4, 5, 6, 7}

(A) {4, 2, 6, 1, 3, 5, 7}
(B) {4, 2, 1, 3, 5, 6, 7}
(C) {7, 6, 5, 4, 2, 1, 3}
(D) {4, 1, 2, 3, 5, 6, 7}

16. Consider the given tree:



The MAX HEAP property is applied on the above tree, (box area), at node with value '6', which of the following is BEST suitable?

(A) First compare 6 and 18 then swap them if required
(B) First compare 6 and 15 then swap them if required.
(C) First compare 18 and 15, then compare the greater element with '6' and swap them if required.
(D) Any one of the above

17. Consider the following statements about Depth First traversal:

I. Suppose we run DFS (Depth First search) on an undirected graph and find exactly 15 back edges. Then the graph is guaranteed to have at least one cycle.
II. DFS on a directed graph with 'n' vertices and at least 'n' edges is guaranteed to find at least one back edge.

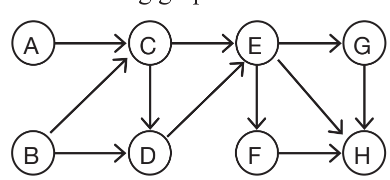
Which of the following is TRUE?

(A) I only (B) II only
(C) Both I and II (D) None of the above

18. Suppose 'G' is a connected, undirected graph, whose edges have positive weights. Let M be a minimum spanning Tree of this graph. We modify the graph by adding '6' to the weight of each edge, which of the following is TRUE?

(A) The order of edges added to minimum spanning tree using kruskal's algorithm, will change.
(B) The modification adds $6(|V| - 1)$ to the total weight of all spanning trees.
(C) The order of edges added to minimum spanning tree using prim's algorithm, will change.
(D) None of the above

19. Consider the following graph:



Which of the following orderings not a valid topological sort of the graph?

(A) BACEDFGH (B) ABCDEFGH
(C) ABCDEGFH (D) BACDEFGH

20. What is the time complexity to print all the keys of a binary search tree in sorted order?

(A) $O(\log n)$ (B) $\theta(n)$
(C) $\theta(n^2)$ (D) $O(n + \log n)$

21. Let T_1, T_2, T_3, T_4, T_4, T_5, T_6 are tasks given along with their deadlines and profits:

Tasks	T_1	T_2	T_3	T_4	T_5	T_6
Deadlines	2	1	3	2	3	1
Profit	6	4	3	7	2	8

Which of the following tasks are not completed?

(A) T_6, T_4, T_3 (B) T_6, T_1, T_2
(C) T_1, T_2, T_5 (D) T_4, T_5, T_6

22. Consider the below program fragment:

```
for i ← 1 to length (A) - 1
{
element ← A [i]
pos ← i
while pos > 0 and A [pos - 1]
{
    A[pos] ← A[pos - 1]
    pos ← pos -1
{
A[pos] ← element.
}
```

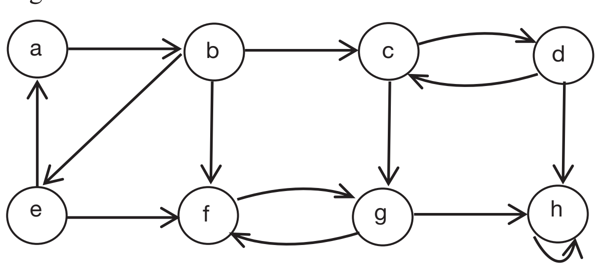
This code implements

(A) Bubble sort (B) Insertion sort
(C) Heap sort (D) Bucket sort

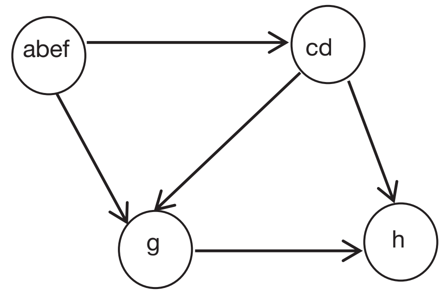
23. What is the best case time complexity of given algorithm in Q. 22?

(A) $\theta(n^2)$ (B) $\theta(\log n)$
(C) $\theta(n)$ (D) $\theta(n \log n)$

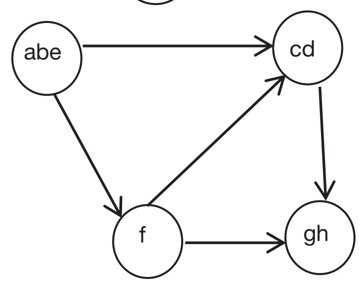
24. Which of the following is an acyclic component graph of given graph using strongly connected components algorithm?



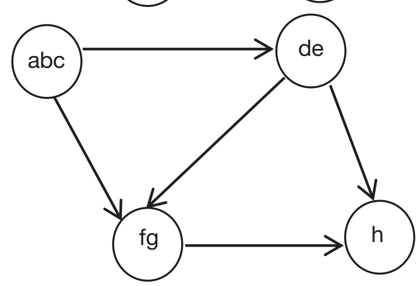
(A)



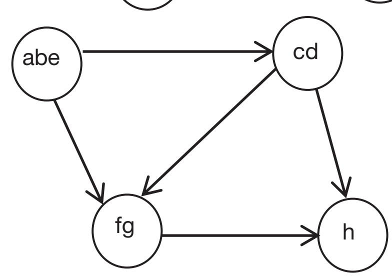
(B)



(A)



(D)



25. Consider an undirected graph

$G = (V, E)$
$V = \{r, s, t, u, v, w, x, y\}$
$E = \{(r,s), (r,v), (s,w), (w,t), (w,x), (t,u), (t,x), (u,y), (u,x)\ (x,y)\}$

Which node has the highest degree?

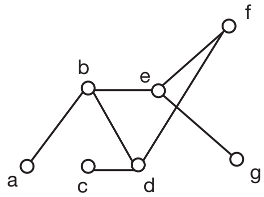
(A) w (B) x
(C) u (D) t

Answer Keys

1. C	**2.** A	**3.** C	**4.** B	**5.** C	**6.** A	**7.** B	**8.** C	**9.** B	**10.** C
11. C	**12.** A	**13.** D	**14.** B	**15.** A	**16.** C	**17.** A	**18.** B	**19.** A	**20.** B
21. C	**22.** B	**23.** C	**24.** D	**25.** B					

Hints and Explanations

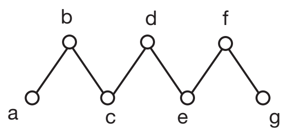
1. A graph without any cycles is called a Tree graph.
Option (C)



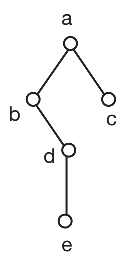
There is a cycle ($b - e - f - d - b$) in the graph.
Choice (C)

2. A tree with 'n' vertices contains (n – 1) edges.
$n - 1 = 57$
Number of vertices, $n = 58$ Choice (A)

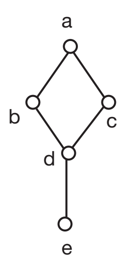
3. **G_1: Example:**



∴ No cycles, It is a tree
G_2: Example:

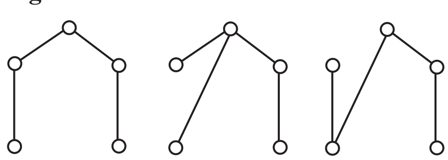


∴ No cycles,
If we have cycle



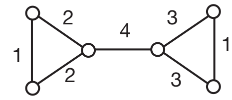
There will be different paths from ($a - e$)
(i) $a - b - d - e$
(ii) $a - c - d - e$
∴ G_2 is also a tree. Choice (C)

4. **Spanning trees:**

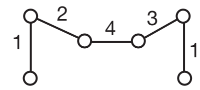


Choice (B)

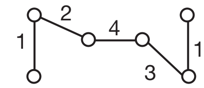
5. Assume the following graph:



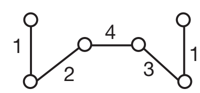
Spanning Tree 1:



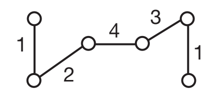
Spanning Tree 2:



Spanning Tree 3:



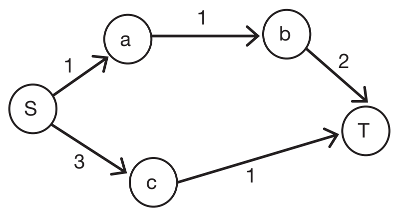
Spanning Tree 4:



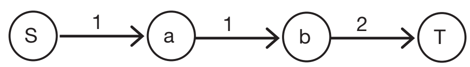
Atmost 4 minimum spanning trees are possible.
Choice (C)

6. I. Dijkstra's algorithm always returns shortest path with minimum total weight.

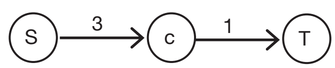
II.



Dijkstra's Algorithm gives, shortest path (length = 3)



But the shortest path

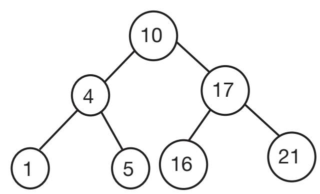


has length = 2
I–TRUE, II–False Choice (A)

7. Dijkstra's is faster than Bellman-Ford, but It cannot work on graphs with negative weight edges.
Choice (B)

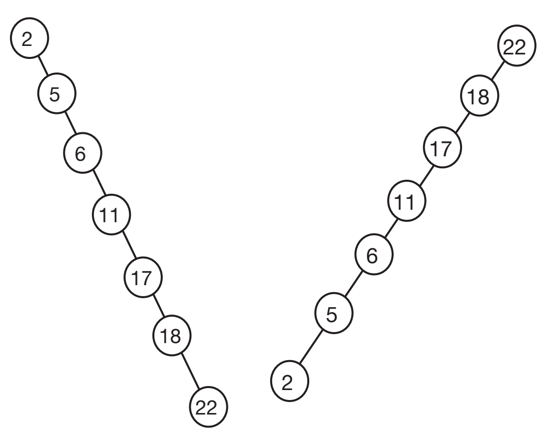
8. Applying BFS on a tree with equal weights results the same tree and it gives minimum distance from root to other nodes. Knapsack fractional problem is optimally solved using greedy design strategy. Choice (C)

9. 1, 4, 5, 10, 16, 17, 21



With height = 2, Internal nodes are 10, 4, 17.
Choice (B)

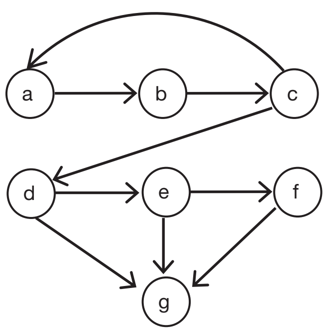
10.



Tree 1: Child 22 Tree 2: Child 2

Choice (C)

11.



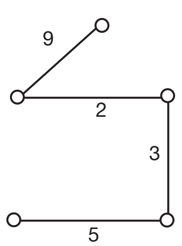
Strongly connected components are:

$\{abc\}$ $\{d\}$ $\{e\}$ $\{f\}$ $\{g\}$

There are five strongly connected components.

Choice (C)

12. Kruskals algorithm is been implemented on the given graph. The bold edges are least weight edges, because the complete spanning tree will contain following edges:



Choice (A)

13. I. Digraph:

There is no limit on number of vertices, In digraph edges will have directions.

I–False

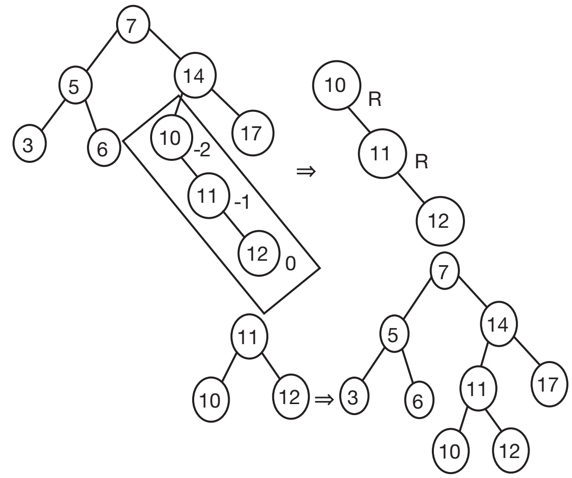
II. Example: **Spanning tree**

II–TRUE

III. There is no optimal solution for Travelling sales person problem.

$\therefore$ Only II is TRUE Choice (D)

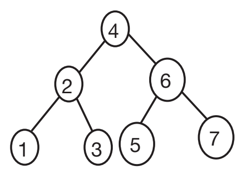
14.



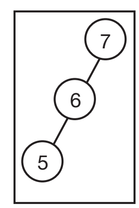
RR–Imbalance: perform Left Rotation.

$\therefore$ 1 Rotation. Choice (B)

15. Option (A):

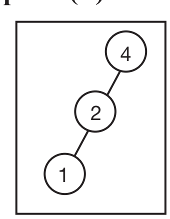


Option (C):



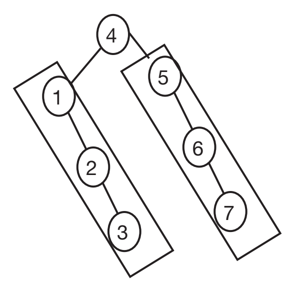
requires LL rotation
for 1st 3 elements

Option (B): **Option (D):**



requires LL rotation

for 1st 3 elements



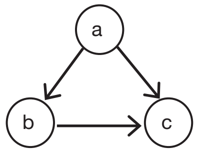
If we have Imbalance, we need to perform Rotation.

Option (A) has no Imbalance. Choice (A)

16. First compare the children of a node. If it is a max heap, then compare the child with greater value to parent node, if required swap them. Choice (C)

17. I. If the graph has a back edge, then it has a cycle.

II.



DFS on the above graph starting at '*a*' does not find any back edge.

∴ I–TRUE, II–False Choice (A)

18. The order of edges added to minimum spanning tree does not change, because we are adding same weight to all the edges.
To the total weight we have to add $6(V-1)$, because in a spanning tree, there will be $(V-1)$ edges, For every edge additional weight '6' is added. Choice (B)

19. **Option (A):**
BACEDFGH
There is an edge from $D \to E$
Where as in the order E appears first and D appears next. Which is invalid.
Check the other options in the same manner.
Choice (A)

20. We can print all the keys of a binary search tree in sorted order using inorder traversal which will take $\theta(n)$ time. Choice (B)

21. Arrange the given tasks according to their profits

Tasks	*T*6	*T*4	*T*1	*T*2	*T*3	*T*5
Profit	8	7	6	4	3	2
Deadline	1	2	2	1	3	3

Order of execution of tasks to maximize the profit

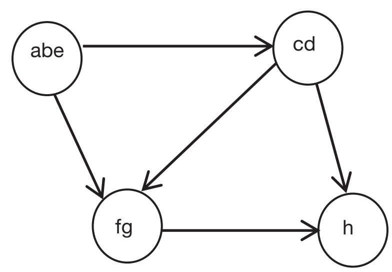
	8	7	3		
	T6	T4	T3		
0	1	2	3	4	5

The uncompleted tasks are *T*1, *T*2, *T*5
Choice (C)

22. The given code implements insertion sort. In insertion sort, every iteration removes an element from the input data and insert it into the correct position in the already sorted list until no input elements remain. Choice (B)

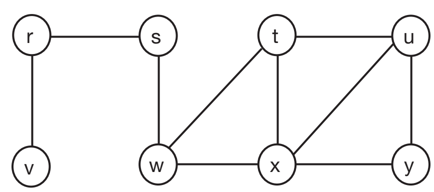
23. The best case input is when the array is already in sorted order. Then time complexity is $\theta(n)$ because in each iteration, the first remaining element of input is only compared with the right-most element of sorted list of the array. Choice (C)

24. Strongly connected components of a directed graph $G = (V, E)$ is a maximal set of vertices $C \subseteq V$ such that for every pair of vertices u and v in C, vertices u and v are reachable from each other. In the given graph the connected components are $\{a, b, e\}$, $\{f, g\}$, $\{c, d\}$ and $\{h\}$.
Hence, the required acyclic component graph will be



Choice (D)

25.



Highest degree node = x(degree = 4) Choice (B)

Chapter 1

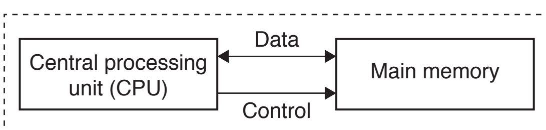
Machine Instructions, Addressing Modes

LEARNING OBJECTIVES

- *Computer*
- *Computer system*
- *Computer component*
- *Machine instruction*
- *Instruction types*
- *Types of operands*
- *Types of operations*
- *Procedure call instruction*
- *Addressing modes*
- *Computer performance*

Computer

A computer is a data-processing machine which is operated automatically under the control of a list of instructions (called a program) stored in its main memory.



Computer System

- A computer system consists usually of a computer and its peripherals.
- Computer peripherals include input devices, output devices and secondary memories.

Computer Architecture: Computer Architecture refers to those attributes of a system visible to a programmer, i.e., the attributes that have direct impact on the logical execution of a program.

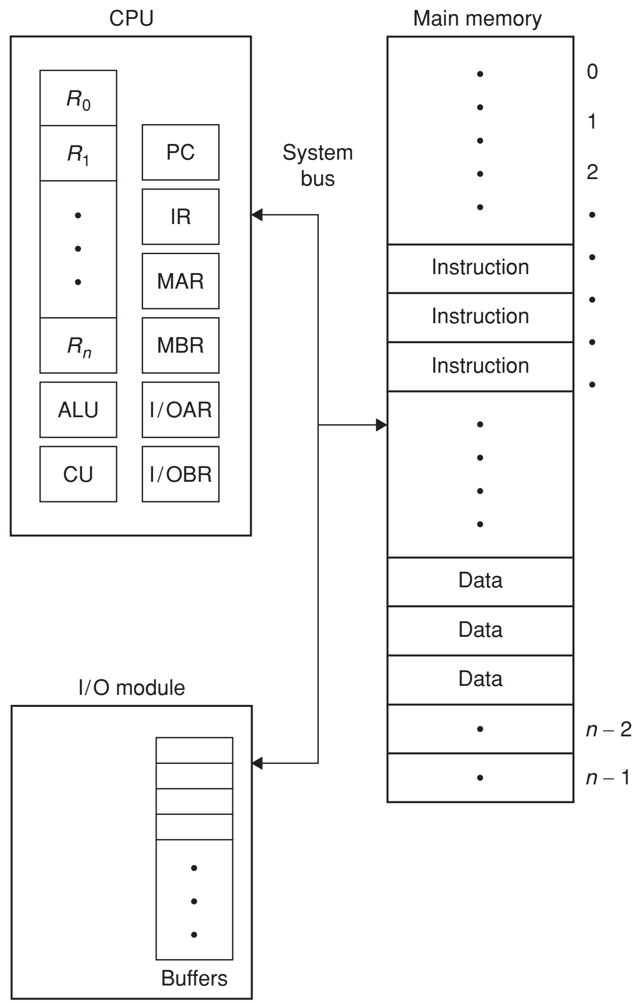
Example: Whether a computer will have a multiply instruction or not.

Computer Organization: Computer organization refers to operational units and their interconnections that realize the architectural specifications.

Example: Whether the multiply instruction will be implemented by a special multiply unit or by a mechanism that makes repeated use of the add unit of the system.

Computer Components

- $R_1, R_2 \ldots R_n$: General Purpose Registers.
- **PC:** Program counter. Holds address of next instruction to be executed. PC = PC + I (I = instruction length)
- **IR:** Instruction Register. It holds the instruction which is fetched from memory.
- **MAR:** Memory Address Register: MAR specifies the address in memory for the next read or write.
- **MBR:** Memory Buffer Register. It contains the data to be written into memory or receives the data read from memory.
- **Input–outputAR:** Input–output Address Register. It specifies a particular input–output device.
- **Input–outputBR:** Input–output Buffer Register. Used for the exchange of data between an input–output module and the CPU.
- **ALU:** Arithmetic and Logic Unit. Used to perform arithmetic and logical operations.



- **CU:** Control Unit. It causes operations to happen within the processor. Also generates timing signals.
- **Memory:** It consists of set of locations, defined by sequential numbered address.
- **Input–output module:** Transfer data from external device to CPU and memory and vice versa.
- **System bus:** A bus that connects major computer components is called a system bus.

Machine Instructions

- The operation of the CPU is determined by the instructions it executes. These instructions are called machine instructions or computer instructions.
- The collection of different instructions that the CPU can execute is referred to as the CPU's instruction set.

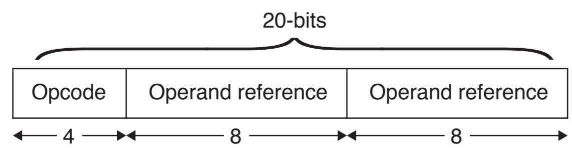
Elements of Machine Instructions

Each instruction must contain the information required by the processor for execution. The elements of a machine instruction are

1. Operation code: Specifies the operation
2. Source operand reference: Inputs for operation.
3. Result operand reference
4. Next instruction reference

Instruction representation

- Each instruction is represented by a sequence of bits.
- Example: 20-bit instruction format:



Instruction Types

Number of addresses

Most of the instructions have one, two or three operand addresses, with the address of next instruction being implicit.

(i) 3-address instructions: Computers with 3-address instruction formats can use each address field to specify either a processor register or a memory operand.

Example: 3-address instruction format for the evaluation of $X = (P + Q) \times (R + S)$ is

ADD R_1, P, Q
ADD R_2, R, S
MUL X, R_1, R_2.

Here R_1, R_2 are processor registers.

Advantage: Shorter programs when evaluating arithmetic expressions.

Disadvantage: The binary coded instructions required too many bits to specify three addresses.

(ii) 2-address instructions: These are most common in commercial computers. Each address field can specify either a processor register or a memory word.

Example: For evaluating $X = (P + Q) \times (R + S)$,

The 2-address instructions are

MOV R_1, P
ADD R_1, Q
MOV R_2, R
ADD R_2, S
MUL R_1, R_2
MOV X, R_1.

(The first symbol of instruction is both source and destination)

(iii) One-address instructions: Use an implied accumulator (AC) register for all data manipulations.

Example: 1-address instructions to evaluate $R = (P + Q) \times (R + S)$.

LOAD P
ADD Q

STORE T
LOAD R
ADD S
MUL T
STORE X.

Here 'T' is a temporary memory location required to store the intermediate result.

(iv) Zero-address instructions: A stack organized computer does not use an address field for the instructions ADD and MUL. The push and pop instructions require an address field to specify the operand that communicates with the stack.

Example: Zero-address instructions for the evaluation of $X = (P + Q) \times (R + S)$

PUSH P
PUSH Q
ADD
PUSH R
PUSH S
ADD
MUL
POP X.

(v) RISC instructions: The instruction set of a reduced instruction set computer (RISC) processor is restricted to the use of load and store instruction when communicating between memory and CPU. All other instructions are executed with in the register of the CPU without referring to memory.

Example: RISC instruction to evaluate,
$X = (P + Q) \times (R + S)$

LOAD R_1, P
LOAD R_2, Q
LOAD R_3, R
LOAD R_4, S
ADD R_1, R_1, R_2
ADD R_3, R_3, R_4
MUL R_1, R_1, R_3
STORE X, R_1

Types of Operands

Machine instructions operate on data. The most important general categories of data are

- Addresses
- Numbers
- Characters
- Logical data.

Types of Operations

The number of different opcodes varies widely from machine to machine. A useful and typical categorization is the following

1. Data transfer
2. Arithmetic
3. Logic
4. Conversion
5. Input–output
6. System control
7. Transfer of control

(i) Data transfer operations: This type of instructions transfers data from one location to another.

Example: move, store, load, exchange, clear, set, push, pop.

(ii) Arithmetic operations: Perform some function in ALU.

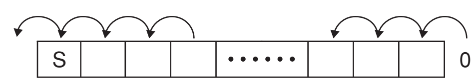
Example: add, subtract, multiply, divide, absolute, negate, increment, decrement

(iii) Logical operations: Perform some logical operation in ALU and set condition codes and flags.

Example: AND, OR, NOT, EX-OR, Test, Compare, set control variables, shift, Rotate.
Let $R_1 = 10100101$, $R_2 = 00001111$ then
(R_1) AND $(R_2) = 00000101$.
AND is also called mask operation.
(R_1) OR $(R_2) = 10101111$.
NOT $(R_1) = 01011010$.
(R_1) EX-OR $(R_2) = 10101010$.

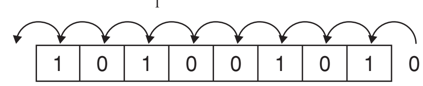
(iv) Shifting and rotating operations: The operations are:

(a) Logical left shift:



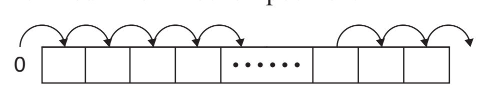
Here the bits of a word are shifted left. The left most bits is lost and 0 is shifted in right most bit position (i.e., bit empty).

Example: $R_1 = 1010\ 0101$
Logical left shift R_1:

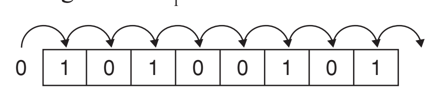


After left shift $R_1 = 0100\ 1010$.

(b) Logical right shift: Here the bits of a word are shifted right. The right most bit lost and '0' is shifted in left most bit position.

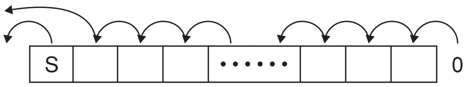


Example: $R_1 = 1010\ 0101$
Logical right shift $R_1 = 0101\ 0010$

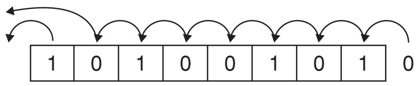


Logical shift operations are useful primarily for isolating fields within a word and also used to displace unwanted information.

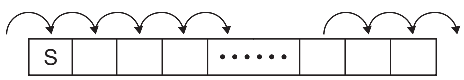
(c) Arithmetic left shift: Arithmetic shift operation treats the data as a signed integer and does not shift the sign bit. In Arithmetic left shift, a logical left shift is performed on all bits but the sign bit, which is retained.



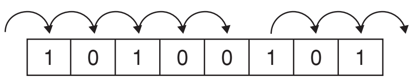
Example: $R_1 = 1010\ 0101$
Arithmetic Left shift $R_1 = 1100\ 1010$.



(d) Arithmetic right shift: Here, the sign bit is replicated into the bit position to its right.



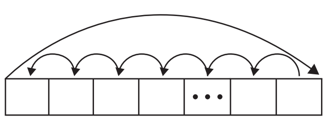
Example: $R_1 = 1010\ 0101$
Arithmetic Right shift $R_1 = 1101\ 0010$



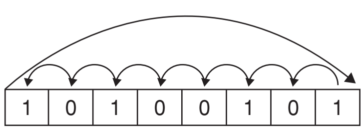
Notes:

1. With numbers in 2's complement form, a right arithmetic shift corresponds to a division by 2, with truncation for odd numbers.
2. Both arithmetic left shift and logical left shift correspond to a multiplication by 2 when there is no overflow.

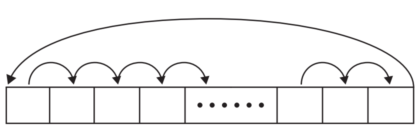
(e) Left rotate (Cyclic left shift): Rotate operations preserve all the bits being operated on. Here the bits from LSB will move one bit position to the left and MSB will placed in LSB position.



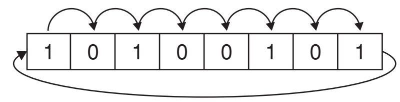
Example: $R_1 = 1010\ 0101$
Left Rotate $R_1 = 0100\ 1011$



(f) Right rotate (Cyclic right shift): Here the bits from MSB will be shifted to one bit position right and LSB is placed in MSB.



Example: R_1: 1010 0101
Right Rotate $R_1 = 1101\ 0010$.



(v) Transfer of control: This type of operations updates the program counter. Used for subroutine call/return, manage parameter passing and linkage.

Example: Jump, jump unconditional, return, execute, skip, skip conditional, Halt, Wait, NOP, etc.

(vi) Input–output operations: These are used to issue a command to input–output module.

Example: input, output, start input–output, test input–output etc.

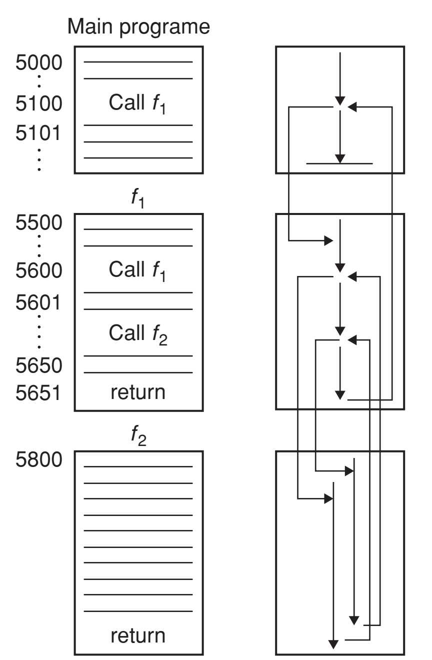
(vii) Conversion operations: These are similar to arithmetic and logical operations. May also involve special logic to perform conversion.

Procedure Call Instruction

A procedure is a self-contained computer program that is incorporated into a large program. It allows us to use the same piece of code many times. The procedure mechanism involves two basic instructions:

1. A call instruction that branches from the present location to the procedure.
2. A return instruction that returns from the procedure to the place from where it was called.

Example:



Call and returns   Execution sequence

We can call a procedure from a variety of points, so the processor must somehow save the return address to return

appropriately. We can store the return address in the following places.

1. Register
2. Start of called procedure
3. Top of stack.

If the register approach is used, call X causes the following actions:

$$RN \leftarrow PC + L$$
$$PC \leftarrow X$$

Where RN is a used to store return address, PC is the program counter and L is instruction length.

To store the return address at the start of the procedure for call X, the following tasks required.

$$X \leftarrow PC + L$$
$$PC \leftarrow X + 1$$

We can pass the parameters using registers or store in memory after call instruction or use stack.

Example 1: Consider the following program fragment in the assembly language of a certain hypothetical processor. The processor has three 8-bit general purpose registers R_1, R_2, R_3.

Instruction	Meaning
X: CMP R_1,0	Compare R_1 and 0, set flags appropriately in status register.
JZ Z	Jump if zero to target Z.
MOV R_2, R_1	Copy contents of R_1 to R_2.
SHR R_1	Shift Right R_1
SHL R_1	Shift left R_1
CMP R_2, R_1	Compare R_2 and R_1 and set flag in status register
JZ Y	Jump if zero to Y.
INC R_3	Increment R_3
Y: SHR R_1	Shift Right R_1 by 1-bit
JMP X	Jump to X
Z: ...	

Let R_1, R_2, R_3 contain the values 3, 0, 0 respectively. What are the final values of R_1, R_2, R_3 when control reaches Z?

(A) 0, 0, 0 (B) 0, 1, 2
(C) 0, 1, 1 (D) 0, 2, 1

Solution: (B)

$R_1 = 0000\ 0011$
$R_2 = 0000\ 0000$
$R_3 = 0000\ 0000$

CMP R_1, 0, As $R_1 \neq 0 \Rightarrow$ Zero flag = 0.
Jump to Z if $Zf = 1$; but $Zf = 0$
MOV R_2, R_1; $R_2 \leftarrow R_1$ i.e., $R_2 = 0000\ 0011$
SHIFT right R_1; $R_1 = 0000\ 0011$
$\Rightarrow$ shr(R_1) = 00000001
SHIFT left R_1; $R_1 = 0000\ 0001 \Rightarrow$ shl (R_1)
$= 0000\ 0010$
Compare R_2, R_1; $R_1 \neq R_2 \Rightarrow ZF = 0$
As Zero flag is not set, increment R_3: $R_3 = 0000\ 0001$
Shift Right R_1; i.e., 0000 0001.
Jump to X.
Compare R_1, 0; As $R_1 \neq 0 \Rightarrow ZF = 0$.
Move R_2, R_1; $R_2 \leftarrow 0000\ 0001$.
Shift right R_1; $R_1 = 0000\ 0000$.
Shift left R_1; $R_1 = 0000\ 0000$.
Compare R_2, R_1; $R_1 \neq R_2 \Rightarrow ZF = 0$.
Increment R_3; $R_3 = 0000\ 0010$.
Shift Right R_1; 0000 0000.
Jump to X.
Compare R_1, 0; As $R_1 = 0 \Rightarrow ZF = 1$
As $ZF = 1$, jump to Z.
$\therefore R_1 = 0$; $R_2 = 1$; $R_3 = 2$.

Addressing Modes

The different ways in which the location of an operand is specified in an instruction are referred to as addressing modes.

Computers use addressing mode techniques for the purpose of accommodating the following provisions:

1. Facilitates pointers to memory.
2. Facilitates counters for loop control
3. Facilitates indexing of data
4. Facilitates program relocation.
5. Reduce the number of bits in the addressing field of the instruction.

The most common addressing techniques are

i. Implied mode
ii. Immediate mode
iii. Direct mode
iv. Indirect mode
v. Register mode
vi. Register Indirect mode
vii. Auto-increment or Auto-decrement mode
viii. Displacement mode
  - PC relative mode
  - Indexed mode
  - Base register mode

(i) Implied mode: Operands are specified implicitly in the definition of the instruction.

Example: CPL (complement accumulator)

Here operand in accumulator is implied in the definition of instruction.

- All register-reference instructions that use an accumulator are implied mode instructions.
- Zero-address instructions in a stack-oriented computer are implied-mode instructions.

(ii) Immediate mode: The operand is specified in the instruction itself. Instruction format in immediate mode is

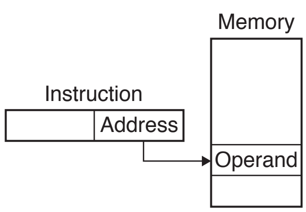
Opcode	Operand

Example: Move A, 50.

- These are useful for initializing registers to constant value or to set initial values of variables.
- No memory reference is required other than the instruction fetch.
- The size of number is restricted to the size of the address (operand) field.

(iii) Direct mode:

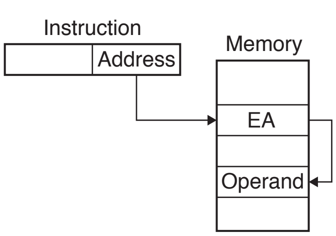
- Here the address of the operand is equal to the address part of the instruction.



- Required only one memory reference and no special calculation required.
- Limitation is limited address space.

(iv) Indirect mode:

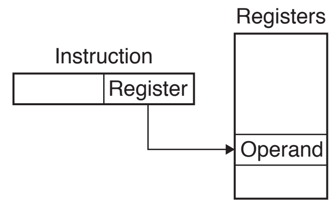
- The address field of the instruction gives the address of the operand which is stored in memory.
- The advantage of this approach is that for a word length of N, an address space of 2^N is available.
- The disadvantage is that the instruction execution requires two memory references to fetch the operand.



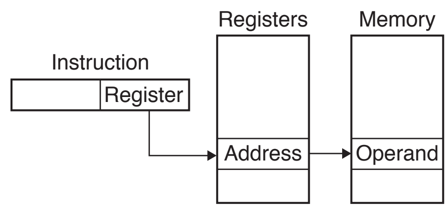
(Here EA is effective address of operand)

(v) Register mode:

- Here the operands are in registers that reside within the CPU.
- Only small address field required in instructions.
- No time consuming memory references are required.
- Address space is very limited.

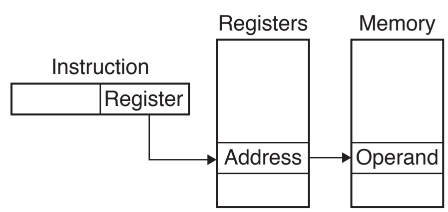


(vi) Register indirect mode: In this mode the instruction specifies a register in the CPU whose contents give the address of the operand in memory. Address field of the instruction uses fewer bits to select a register than would have required to specify a memory address directly.



Effective address: The effective address is defined to be the memory address obtained from the computation based on the addressing mode, consists the actual address of the operand.

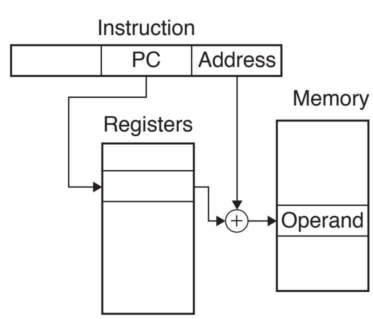
(vii) Auto increment and auto decrement mode: This is similar to register indirect mode except that the register is incremented or decremented after (or before) its value is used to access memory.



- After fetch operand, increment or decrement address.
- Used to access table of data.

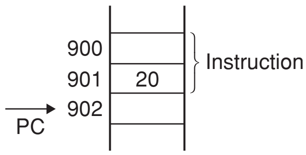
(viii) PC-relative mode: Here the content of the program counter is added to the address part of the instruction to get the effective address.

The address part of the instruction is usually a signed number which can be either positive or negative. The effective address will be a displacement relative to address of the inst ruction.



Effective address = PC + address part

Example: Let PC = 900 and address part of the 2-word instruction = 20.

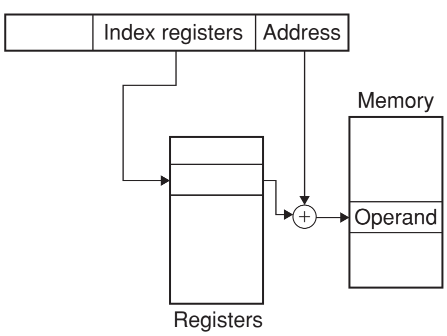


The instruction at location 900 is read memory during fetch phase and the PC will be incremented by instruction length i.e., 2. Then PC = 902.

∴ The effective address using PC-relative = 902 + 20 = 922.

- This addressing mode is used with branch-type instructions.
- Requires shorter address field.

(ix) Indexed mode: Here the content of the index register is added to the address part of the instruction to obtain the effective address. The address field of the instruction defines the beginning address of a data array in memory. The distance between the beginning address and the address of the operand is the index value stored in the index register, is a positive displacement from the address.



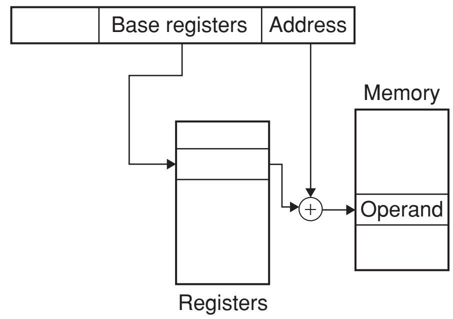
Effective Address = Index Register + Address part of instruction.

This approach is opposite to the interpretation of base-register addressing. This is used to provide an efficient mechanism for performing iterative operations. To store an array using indexed mode, the address part consists of the address of first element of array and the index register specifies the index value.

Example: Let address part of instruction = 300

Index register = 5 and each element of array requires 2 bytes then address of 5th element = $300 + 5 \times 2 = 310$.

(x) Base Register mode: Here the content of a base register is added to the address part of the instruction to obtain the effective address. Base register has a base address and the address field of the instruction gives a displacement relative to the base address.



This addressing mode is used in computers to facilitate the relocation of programs in memory, i.e., when programs and data are moved from one segment of memory to another, as required in multiprogramming system, the address values of instructions must reflect this change of position. With a base register, the displacement values of instructions do not have to change. Only the value of the base register requires updating to reflect the beginning of a new memory segment.

Example 2: If base register is 200 and address part of the instruction is 31, then effective address = 200 + 31 = 231.

If the program's base address is changed from 200 to 400, then new effective address will be 400 + 31 = 431.

Example 3: Match the following:

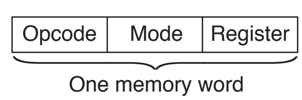
	LIST I		LIST II
P.	P[i] = Q[i];	**1.**	Indexed mode
Q.	while(i++);	**2.**	Immediate mode
R.	int i = 10;	**3.**	Auto increment mode

(A) P – 1, Q – 2, R – 3 (B) P – 2, Q – 3, R – 1
(C) P – 1, Q – 2, R – 2 (D) P – 1, Q – 2, R – 2

Solution: (C)

Array indexing uses indexed mode. For increment operations use Auto increment mode. To initialize variables use immediate mode.

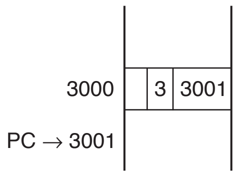
Example 4: The instruction format of a CPU is



Mode and Register together specifies the operand. Register specifies a CPU register and mode specifies an addressing mode. Let mode = 3, specifies that the register contains the address of the operand, after fetching the operand, the contents of register are incremented by 1. An instruction at memory location 3000 specifies mode = 3 and register refers to program counter (PC). Then what is the address of the operand?

(A) 3000 (B) 3001
(C) 3002 (D) Data insufficient

Solution: (B)



$\therefore$ Address of operand = 3001

Example 5: Consider the following machine instruction:

$$\text{MUL } P[R_0], @Q$$

The first operand (destination) '$P[R_0]$' uses indexed addressing mode with R_0 as the index register. The second operand (source) '$@Q$' uses indirect addressing mode. P and Q are memory addresses residing at the second and third words respectively. The first word of instruction specifies the opcode, the index register designation, source and destination addressing modes. During the execution of MUL, the result is stored in destination. How many memory cycles needed during the execution cycle of the instruction?

(A) 3 (C) 5
(B) 4 (D) 6

Solution: (C)
The first operand $P[R_0]$ uses indexed mode. So it requires two memory references: on reference to the address part and next one to obtain the operand. The second operand $@Q$ uses indirect addressing mode, so it requires two memory references, one to obtain the address, and the second, to obtain operand. Finally one more memory reference required to store result. Total five references.

Computer Performance

Response time: The time between the start and completion of a task. This is also referred as execution time.

Throughput: The total amount of work done in a given time.

Performance can be defined as Performance

$$\text{Pertermance} = \frac{1}{\text{Execution time}}$$

CPU execution time or CPU time: This is the time the CPU spends computing for the task and does not include time spent waiting for input–output or running other programs.

CPU time can be divided into

1. User CPU time
2. System CPU time

User CPU time: CPU time spent in the program.

System CPU time: CPU time spent in the operating system performing tasks on behalf of the program.

Clock cycle: Computers are constructed using a clock that determines when events take place in the hardware. These discrete time intervals are called clock cycles.

Clock period: The length of each clock cycle.

Clock rate: Inverse of the clock period.

CPU execution time for a program = CPU clock cycles for a program * clock cycle time

$$= \frac{\text{CPU clock cycles for a program}}{\text{Clock rate}}$$

CPU clock cycles = Instructions for a program * Average clock cycles per instructions.

CPI (clock cycles per instructions): CPI is the average number of clock cycles each instruction takes to execute.

CPU Performance Equation:
CPU time = Instruction count * CPI * Clock cycle time

$$= \frac{\text{Instruction count} * \text{CPI}}{\text{Clock rate}}$$

Exercises

Practice Problems I

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. An instruction is stored at location 301 with its address field at location 300. The address field has the value 400. A processor register R_1 contains the number 200. Evaluate the effective address and Match the following:

(A) Direct	(1) 702
(B) Immediate	(2) 600
(C) Relative	(3) 301
(D) Register Indirect	(4) 400
(E) Index with R_1 as index Register	(5) 200

(A) A – 4, B – 3, C – 1, D – 5, E – 2
(B) A – 3, B – 4, C – 1, D – 5, E – 2
(C) A – 4, B – 3, C – 1, D – 2, E – 5
(D) A – 3, B – 3, C – 1, D – 2, E – 5

2. The two word instruction is stored in memory at an address designated by symbol W. The address field of the instruction (stored at $W + 1$) is designated by the symbol Y. The operand used during the execution of the instruction is stored at address symbolized by Z. An index register contains the value X. State how Z is calculated from the other addresses if the addressing mode of the instruction is

(A) Direct	(1) $Z = \text{Mem}(Y)$
(B) Indirect	(2) $Z = Y + W + 2$

(C) Relative (3) $Z = Y + X$
(D) Indexed (4) $Z = Y$

(A) A – 4, B – 1, C – 2, D – 3
(B) A – 3, B – 1, C – 2, D – 4
(C) A – 4, B – 2, C – 1, D – 3
(D) A – 3, B – 2, C – 1, D – 4

3. A computer has 32-bit instruction and 12-bit addresses. If there are 250 two-address instructions, how many one-address instructions can be formulated?
(A) 6 (B) 256
(C) 12,288 (D) 24,576

4. The memory unit of a computer has 256k words of 32-bits each. The computer has an instruction format with four fields:

1. An operation field
2. A mode field to specify one of 8 addressing modes
3. A Register address field to specify one of 120 processor registers.
4. A memory address.

Then what is the number of bits in each field respectively if the instruction is in one memory word?
(A) 4, 3, 7, 18 (B) 3, 4, 7, 18
(C) 2, 1, 6, 23 (D) 3, 7, 4, 18

Common data for questions 5 to 7: A relative mode branch type of instruction is stored in memory at an address equivalent to decimal 750. The branch is made to an address equivalent to decimal 400.

5. What should be the value of the relative address field of the instruction in decimal?
(A) 351 (B) −351
(C) 350 (D) −350

6. The relative address value in binary using 12-bits, will be
(A) 000101011111 (B) 100101011111
(C) 111010100000 (D) 111010100001

7. What will be the binary value in PC after the fetch phase (in binary)?
(A) 001011101111 (B) 001011101110
(C) 111011101111 (D) 110100010001

Common data for questions 8 to 10: Consider a 16-bit processor in which the following appears in main memory, starting at location 200:

200	Load to AC	Mode
201	500	
202	Next to instruction	

The first part of the first word indicates that this instruction loads a value into an accumulator. The mode field specifies an addressing mode or a source register, R_1, which has a value 400. There is a base register that contain the value 100. The value 500 in location 201, may be the part of address calculation. Assume that location 399 contains the value 999, location 400 contains the value 1000 and so on.

8. What will be the effective address and operand to be loaded by using Register indirect mode?
(A) 200, 400 (B) 400, 1000
(C) 400, 500 (D) 200, 1000

9. What will be the effective address using indirect addressing mode?
(A) 200 (B) 201
(C) 500 (D) Present in 500 location

10. What will be the effective address using immediate addressing mode?
(A) 202 (B) 201
(C) 500 (D) 400

11. A CPU of a computer has 48-bit instructions. A program starts at address $(600)_{10}$. Which one of the following is a legal program counter value in decimal?
(A) 610 (B) 650
(C) 672 (D) 693

12. Consider a new instruction named branch- on-bit-reset (bbr). The instruction '*BBR* R_1, I, label'

Jumps to label, and if bit in position I of register operand, R_1 is zero. The registers of the computer are 16-bits wide and are numbered 0 to 15, position 0 being LSB. Consider the following implementation of this instruction on a processor that does not have *BBR* implemented.

Temp ← R_1 and mask

Branch to label if temp is zero.

The variable 'temp' is a temporary register. For correct implementation, the variable 'mask' must be generated by
(A) mask $\leftarrow 0 \times 1 << I$
(B) mask $\leftarrow 0 \times FFFFFFFF >> I$
(C) mask $\leftarrow I$
(D) mask $\leftarrow 0 \times F$.

13. Consider a hypothetical processor with an instruction of type

LW R_1, 40(R_2)(R_3).

Which during execution reads a 16-bit word from memory and stores it in a 16-bit register R_1. The effective address of the memory location is obtained by the addition of constant 40, contents of R_2 and R_3 registers. Which of the following best reflects the addressing mode implemented by this instruction for the operand in memory?
(A) Immediate addressing
(B) Register addressing
(C) Register indirect scaled addressing
(D) Base with index and displacement addressing

14. Which of the following is true of base-register addressing mode?
(i) It is useful in creating self-relocating code.
(ii) If it is included in an instruction set architecture, then an additional ALU is required for effective address calculation.
(iii) The amount of displacement depends on the content of base register.
(A) (i) only (B) (ii) only
(C) (i) and (ii) only (D) (ii) and (iii) only

15. Which of the following addressing modes are suitable for program relocation at run time?
(i) Direct addressing
(ii) Based register addressing
(iii) PC-relative addressing
(iv) Index register addressing
(A) (i) and (ii) (B) (ii) and (iii)
(C) (iii) and (iv) (D) (ii), (iii) and (iv)

16. In which of the following addressing mode, the address of the operand is inside the instruction?
(A) Implied mode
(B) Absolute addressing mode
(C) Immediate addressing mode
(D) Register addressing mode

17. A certain processor supports only the immediate and the direct addressing modes. Which of the following programming language features can be on this processor?
(i) Pointers
(ii) Arrays
(iii) Initialization
(A) (i) and (ii) (B) (i) and (iii)
(C) (ii) and (iii) (D) (iii) only

18. In which of the following situation, relative addressing mode is useful?
(A) Coroutine writing
(B) Position-independent code writing
(C) Sharable code writing
(D) Interrupt handlers

19. In indexed addressing mode with scaling, the effective address is calculated as
(A) Index + scaling + signed displacement
(B) (Index * scaling) + signed displacement
(C) Index + (scaling * displacement)
(D) (Index + scaling) * displacement

20. Which of the following addressing modes require more number of memory accesses?
(A) DIRECT
(B) IMMEDIATE
(C) INDIRECT
(D) IMPLIED

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. The addressing mode that facilitates access to an operand and whose location is defined relative to the beginning of the data structure in which it appears is
(A) Direct (B) Indirect
(C) Immediate (D) Index

2. Stack addressing is same as
(A) Direct addressing
(B) Indirect addressing
(C) Zero addressing
(D) Relative addressing

3. The Register which contain the Instruction to be executed is called
(A) Instruction register
(B) Memory address register
(C) Index register
(D) Memory data register

4. The Register which keeps track of the execution of a program and which contains the memory address of the next instruction to be executed is called
(A) Instruction register
(B) Program counter
(C) Index register
(D) Memory address register

5. A stack pointer is
(A) A 16-bit register in the microprocessor that indicate the beginning of the Stack Memory
(B) A register that decodes and execute 16-bit arithmetic operation.
(C) The first memory location where a subroutine address is stored
(D) A register in which flag bits are stored.

6. Function of Control Unit in the CPU is
(A) To transfer data to primary storage
(B) To store program instruction
(C) To perform logic operations
(D) To generate timing signals

7. When a subroutine is called the address of the instruction following the CALL instruction stored in the
(A) Stack (B) Accumulator
(C) Program counter (D) Stack pointer

8. In Immediate addressing mode the operand is placed
(A) In the CPU Register
(B) After the OP Code in the instruction
(C) In the memory
(D) In the stack memory

9. When the RET instruction at the end of subroutine is executed
(A) The information where the stack is initialized is transferred to the stack pointer.
(B) The memory address of the RET instruction is transferred to the program counter.
(C) Two data bytes stored in the top two locations of the stack are transferred to the program counter.
(D) Two data bytes stored in the top two location of the stack are transferred to the stack pointer.

10. Match the following:

List I	List II
P. Indirect Addressing	**1.** Loops
Q. Auto decrement Addressing	**2.** Constants
R. Immediate Addressing	**3.** Pointers

(A) P – 1, Q – 3, R – 2
(B) P – 3, Q – 1, R – 2
(C) P – 2, Q – 1, R – 3
(D) P – 3, Q – 2, R – 1

11. An instruction used to set the carry flag in a computer can be
(A) Data control (B) Process control
(C) Logical (D) Data transfer

12. The addressing mode in which the address of the location of the operand is given explicitly as part of the instruction is
(A) Direct addressing mode
(B) Indirect addressing mode
(C) Immediate addressing mode
(D) Register addressing mode

13. The unit that is used to supervise each instructions in the CPU is
(A) Control register (B) Control logic unit
(C) ALU (D) Address register

14. The address of the location to or from which data are to be transferred is called
(A) Memory data register
(B) Memory address register
(C) Program counter
(D) Index register

15. Which register is used as a working area in CPU?
(A) Program counter (B) Accumulator
(C) Stack pointer (D) Instruction register

16. Which of the following statement is false about the PC relative addressing mode?
(A) It allows indexing of array element with same instruction.
(B) It enables reduced instruction size.
(C) It enables faster address calculations than indirect addressing.
(D) It enables easy relocation of data.

17. Which of the following is not an application of logic operations?
(A) Insert new bit values into a register
(B) Change bit value
(C) Delete a group of bits
(D) Shift bit values in a register

18. In which of the following addressing mode, less number of memory references are required?
(A) Immediate (B) Register
(C) Implied (D) All of the above

19. Which of the following is not involved in a memory write operation?
(A) MDR (B) MAR
(C) PC (D) Data bus

20. In ____ addressing mode the instruction contains 8-bit signed offset, address register A_n and index register R_K.
(A) Basic index (B) Full index
(C) Basic relative (D) Full relative

Previous Years' Questions

Common Data for Questions 1 to 3: Consider the following program segment. Here R_1, R_2 and R_3 are the general purpose registers.

Instruction		Operation	Instruction Size (No. of Words)
	MOV R_1, (3000)	$R_1 \leftarrow$ M[3000]	2
LOOP:	MOV R_2, (R_3)	$R_2 \leftarrow$ M[R_3]	1
	ADD R_2, R_1	$R_2 \leftarrow R_1 + R_2$	1
	MOV (R_3), R_2	M[R_3] $\leftarrow R_2$	1
	INC R_3	$R_3 \leftarrow R_3 + 1$	1
	DEC R_1	$R_1 \leftarrow R_1 - 1$	1
	BNZ LOOP	Branch on not zero	2
	HALT	Stop	1

Assume that the content of memory location 3000 is 10 and the content of the register R_3 is 2000. The content of each of the memory locations from 2000 to 2010 is 100. The program is loaded from the memory location 1000. All the numbers are in decimal.

1. Assume that the memory is word addressable. The number of memory references for accessing the data

in executing the program completely is: **[2007]**

(A) 10 (B) 11
(C) 20 (D) 21

2. Assume that the memory is word addressable. After the execution of this program, the content of memory location 2010 is: **[2007]**

(A) 100 (B) 101
(C) 102 (D) 110

3. Assume that the memory is byte addressable and the word size is 32 bits. If an interrupt occurs during the execution of the instruction 'INC R_3', what return address will be pushed on to the stack? **[2007]**

(A) 1005 (B) 1020
(C) 1024 (D) 1040

4. Which of the following is/are true of the auto-increment addressing mode?

(i) It is useful in creating self-relocating code
(ii) If it is included in an Instruction Set Architecture, then an additional ALU is required for effective address calculation
(iii) The amount of increment depends on the size of the data item accessed **[2008]**

(A) (i) only (B) (ii) only
(C) (iii) only (D) (ii) and (iii) only

5. Consider a hypothetical processor with an instruction of type LW R_1, 20(R_2), which during execution reads a 32-bit word from memory and stores it in a 32-bit register R_1. The effective address of the memory location is obtained by the addition of a constant 20 and the contents of register R_2. Which of the following best reflects the addressing mode implemented by this instruction for the operand in memory? **[2011]**

(A) Immediate addressing
(B) Register addressing
(C) Register indirect scaled addressing
(D) Base indexed addressing

6. Consider two processors P_1 and P_2 executing the same instruction set. Assume that under identical conditions, for the same input, a program running on P_2 takes 25% less time but incurs 20% more CPI (Clock cycles per instructions) as compared to the program running on P_1. If the clock frequency of P_1 is 1GHz, then the clock frequency of P_2 (in GHz) is ______. **[2014]**

7. A machine has a 32-bit architecture with 1-word long instructions. It has 64 registers, each of which is 32 bits long. It needs to support 45 instructions, which have an immediate operand in addition to two register operands. Assuming that the immediate operand is an unsigned integer, the maximum value of the immediate operand is ________. **[2014]**

8. Consider a new instruction named branch-on-bit-set (mnemonic bbs). The instruction 'bbs reg, pos, label' jumps to label if bit in position pos of register operand reg is one. A register is 32 bits wide and the bits are numbered 0 to 31, bit in position 0 being the least significant. Consider the following emulation of this instruction on a processor that does not have bbs implemented.

temp ← reg & mask

Branch to label if temp is non-zero.

The variable temp is a temporary register. For correct emulation, the variable mask must be generated by **[2006]**

(A) mask ← 0 × 1 << pos
(B) mask ← 0 × ffffffff >> pos
(C) mask ← pos
(D) mask ← 0 × f

9. Consider a processor with byte-addressable memory. Assume that all registers, including Program Counter (PC) and Program Status Word (PSW), are of size 2 bytes. A stack in the main memory is implemented from memory location $(0100)_{16}$ and it grows upward. The stack pointer (SP) points to the top element of the stack. The current value of SP is $(016E)_{16}$. The CALL instruction is of two words, the first word is the op-code and the second word is the starting address of the subroutine (one word = 2 bytes). The CALL instruction is implemented as follows:

- Store the current value of PC in the stack
- Store the value of PSW register in the stack
- Load the starting address of the subroutine in PC

The content of PC just before the fetch of a CALL instruction is $(5FA0)_{16}$. After execution of the CALL instruction, the value of the stack pointer is **[2015]**

(A) $(016A)_{16}$ (B) $(016C)_{16}$
(C) $(0170)_{16}$ (D) $(0172)_{16}$

10. A processor has 40 distinct instructions and 24 general purpose registers. A 32 - bit instruction word has an opcode, two register operands and an immediate operand. The number of bits available for the immediate operand field is ____. **[2016]**

11. Suppose the functions F and G can be computed in 5 and 3 nanoseconds by functional units U_F and U_G, respectively. Given two instances of U_F and two instances of U_G, it is required to implement the computation $F(G(X_i))$ for $1 \le i \le 10$. Ignoring all other delays, the minimum time required to complete this computation is _____ nanoseconds. **[2016]**

12. Consider a processor with 64 registers and an instruction set of size twelve. Each instruction has five distinct fields, namely, opcode, two source register identifiers, one destination register identifier, and a twelve - bit immediate value. Each instruction must be stored in

memory in a byte - aligned fashion. If a program has 100 instructions, the amount of memory (in bytes) consumed by the program text is ____. **[2016]**

13. Consider the C struct defined below:

```
struct data  {
    int marks [100];
    char grade;
    int cnumber;
};
struct data student;
```

The `base` address of `student` is available in register R1. The field `student.grade` can be accessed efficiently using **[2017]**

(A) Post-increment addressing mode, $(R1)+$
(B) Pre-decrement addressing mode, $-(R1)$
(C) Register direct addressing mode, $R1$
(D) Index addressing mode, $X(R1)$, where X is an offset represented in 2's complement 16-bit representation.

14. Consider a RISC machine where each instruction is exactly 4 bytes long. Conditional and unconditional branch instructions use PC-relative addressing mode Offset specified in bytes to the target location of the branch instruction. Further the Offset is always with respect to the address of the next instruction in the program sequence. Consider the following instruction sequence.

Instr.No.	Instruction
i :	add R2, R3, R4
i+1 :	sub R5, R6, R7
i + 2 :	cmp R1, R9, R10
i + 3 :	beq R1, Offset

If the target of the branch instruction is i, then the decimal value of the Offset is ______. **[2017]**

15. A processor has 16 integer registers ($R0, R1, ..., R15$) and 64 floating point registers ($F0, F1, ..., F63$). It uses a 2-byte instruction format. There are four categories of instructions: Type-1, Type-2, Type-3, and Type-4. Type-1 category consists of four instructions, each with 3 integer register operands ($3Rs$). Type-2 category consists of eight instructions, each with 2 floating point register operands ($2Fs$). Type-3 category consists of fourteen instructions, each with one integer register operand and one floating point register operand ($1R + 1F$). Type-4 category consists of N instructions, each with a floating point register operand ($1F$).

The maximum value of N is ______. **[2018]**

ALU (Arithmetic and Logic Unit)

ALU performs arithmetic and logical operations on data (*see* Figure 1).

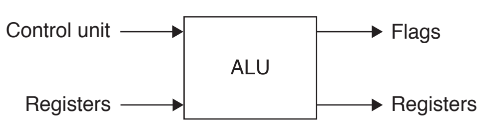

Figure 1 ALU inputs and outputs

- Data are presented to ALU in registers and the results of an operation are stored in registers.
- Registers are temporary storage locations within the processor that are connected by signal paths to ALU.
- The control unit provides signals that control the operation of ALU and the movement of data into and out of the ALU.
- Here we will discuss
  1. Fixed-point arithmetic operations
  2. Floating-point arithmetic operations
  3. BCD data arithmetic operations

Fixed-point Arithmetic Operations

Fixed-point representation

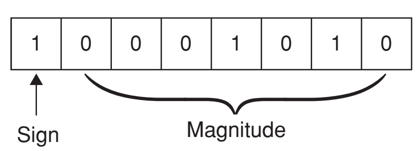
The numbers may be positive, zero or negative. So we have two types of numbers:

Unsigned numbers Only zero and positive integers can be represented. All bits represent magnitude and no need of sign.

Signed numbers In signed representation, the most significant bit represents the sign. If the number is positive, the MSB is 0 and remaining bits represent magnitude. If the number is negative, we have three techniques to represents that number:

1. **Signed magnitude representation:** In signed magnitude representation, the MSB represents sign and remaining bits represents magnitude. If the number is negative then the MSB is 1.

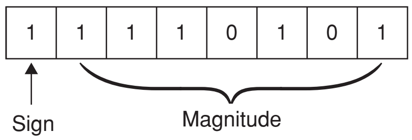
   Example: Signed magnitude representation of –10 =



2. **Signed 1's complement representation:** In signed 1's complement representation, the MSB bit is 1. The remaining bits of its signed magnitude bits are inverted i.e., convert 0's to 1's and 1's to 0's to obtain 1's complement.

Example:

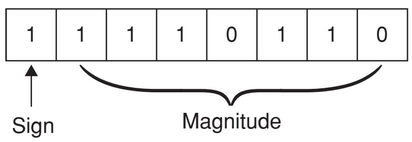
Signed 1's complement (–10) =



3. **Signed 2's complement representation:** To get signed 2's complement representation, add 1 to the signed 1's complement of that number.

Example:

Signed 2's complement (–10) =



Fixed-point arithmetic operations

We will discuss the following operations using signed magnitude data and signed 2's complement data.

1. Addition
2. Subtraction
3. Multiplication
4. Division

Addition and subtraction using signed magnitude data Consider two numbers whose magnitude is represented as A and B. When the signed numbers are added or subtracted, there are eight different conditions to consider, depending on the sign of the numbers and operation performed.

Operation	Add Magnitudes	Subtract Magnitudes ($A > B$)
$(+A) + (+B)$	$+(A + B)$	
$(+A) + (-B)$		$+(A - B)$
$(-A) + (+B)$		$-(A - B)$
$(-A) + (-B)$	$-(A + B)$	
$(+A) - (+B)$		$+(A - B)$
$(+A) - (-B)$	$+(A + B)$	
$(-A) - (+B)$	$-(A + B)$	
$(-A) - (-B)$		$-(A - B)$

Algorithm for addition (subtraction): When the signs of A and B identical (different), add the two magnitudes and attach the sign of A to the result. When the signs of A and B are different (identical), compare the magnitudes and subtract the smaller number from the larger. Choose the sign of result based on magnitudes of A and B.

Example: All eight cases for the numbers $A = 5$, $B = 2$.

$(+A) + (+B) = (+5) + (+2)$
$= 0101 + 0010 = 0111 = +7$
$(+A) + (-B) = (+5) + (-2)$
$= 0101 + 1010$

Take 2's complement of –2 and add it to 5

101
110

1] 011
↑
Discard

$\therefore$ result = + 3 ($A > B$)

$(-A) + (+B) = (-5) + (+2)$
$= 1101 + 0010$

add 2's complement of –5 to 2

011
<u>010</u>
<u>101</u>

As MSB is 1 take 2's complement to get original number i.e., 011.

Result = 1011 = –3 ($\because A > B$)

$(-A) + (-B) = (-5) + (-2)$
$= 1101 + 1010$

101
<u>010</u>

Result = 1111 = –7

Similarly we can perform the subtractions using signed magnitude data.

Hardware implementation:

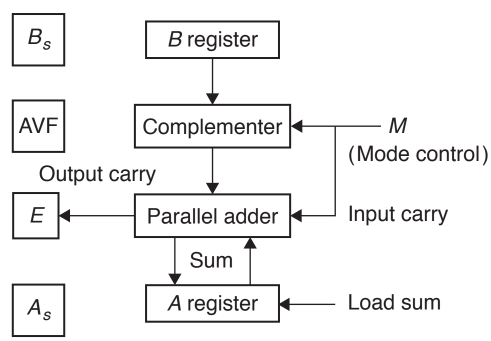


Figure 2 Hardware implementation for addition and subtraction.

Figure 2 shows the hardware implementation for addition and subtraction operations. It consists of registers A and B and sign flip-flops A_s and B_s. Subtraction is done by adding A to the 2's complement of B. The output carry is transferred to flip-flop E and add overflow flip-flop AVF holds the overflow bit when A and B are added. The addition is done through the parallel adder. The output of adder is sent to 'A' register. The complementer provides an output of B or complement of B depending on the state of mode control M. When $M = 0$, the output equal to $A + B$, when $M = 1$, the output equal to $A + \overline{B} + 1$, i.e., $A - B$.

Addition and Subtraction with signed 2's complement data

Addition: In 2's complement representation, addition proceeds as if the two numbers were unsigned integers. If the result of the operation is positive, we get a positive number

in 2's complement form, which is same as in unsigned integer form. If the result of the operation is negative, we get a negative number in 2's complement form.

Example:

+5 = 0101
+2 = 0010
0111 = +7

+5: 0101
−2: 1110
10011 = +3
−5: 101
+2: 0010
1101

As the result is negative, take 2's complement of result to get original number, i.e., 0011 and the answer is −3.

−5: 1011
−2: 1110
11001

As the result is negative take 2's complement to get original number, i.e., 0110 + 1 = 0111.

∴ Answer is −7.

Note: If two numbers are added and they are both positive or both negative, then overflow occurs if the result has the opposite sign.

Subtraction: To subtract subtrahend from minuend, take the 2's complement of subtrahend and add it to the minuend.

Example:

+5: 0101
+2: 0010

To subtract these two numbers add 2's complement of 2 to 5.

+5: 0101
−2: 1110
10011 = +3
+5: 0101
− 2: 1110

2's complement of −2 = 0010.

+5: 0101
+2: 0010
0111 = +7

Similarly for the other cases we can perform the subtraction.

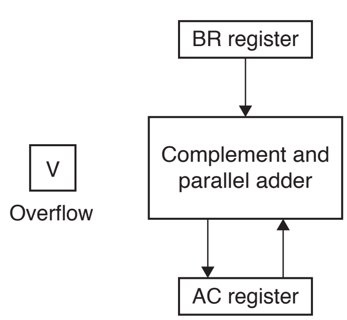

Figure 3 Hardware implementation for signed 2's complement addition and subtraction:

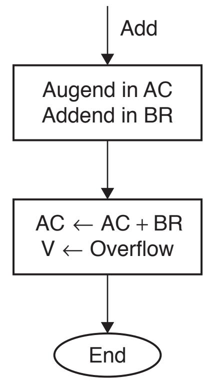

Figure 4 Flowchart for addition in 2's complement form

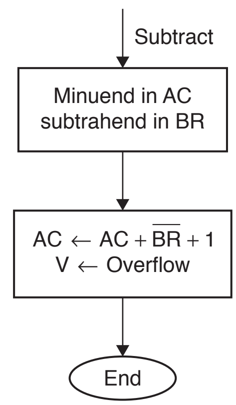

Figure 5 Flowchart for subtraction of 2's complement data

Multiplication of signed magnitude data

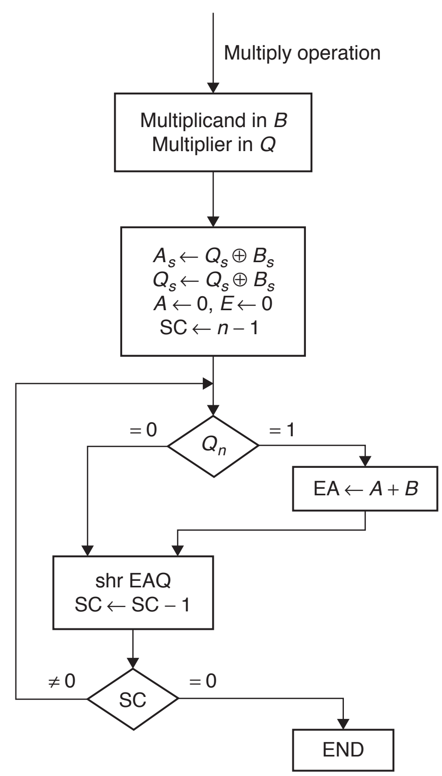

Figure 6 Flowchart for multiplication of signed magnitude data

Multiplication of two fixed point binary numbers in signed magnitude representation is a process of successive shift and add operations (*see* Figure 6).

Example 1: Multiply the two numbers −7 and +8, using 5-bit registers.
−7 = 10111
+8 = 01000

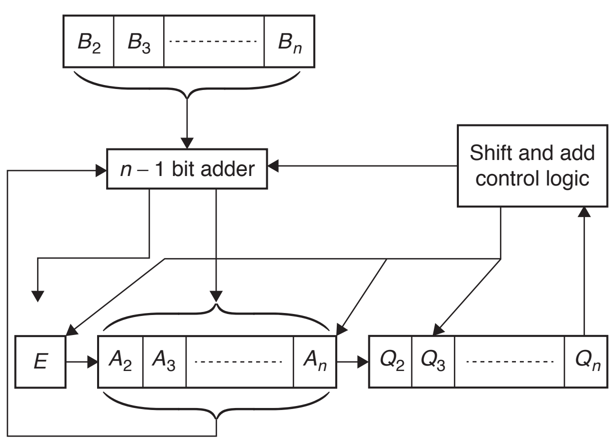
By excluding sign-bits, the multiplicand, B = 0111 and multiplier Q = 1000. Initially A = 0000, SC is sequence counter contains number of bits in multiplier magnitude.

Here SC = 4

Multiplicand **B = 0111**	***E***	***A***	***Q***	**SC**
Multiplier in Q	0	0000	1000	4
Last bit of Q, $Q_n = 0 \Rightarrow$ Shr EAQ	0	0000	0100	3
$Q_n = 0 \Rightarrow$ Shr EAQ	0	0000	0010	2
$Q_n = 0 \Rightarrow$ Shr EAQ	0	0000	0001	1
$Q_n = 1 \Rightarrow$ Add B to A	0	0000 <u>0111</u> 0111	0001	
Shr EAQ	0	0011	1000	0

$B \times Q = 00111000 = 56$
Sign $= Q_s \oplus B_s = 1 \oplus 0 = 1$
∴ Result = –56

Hardware for signed magnitude data multiplication: B_1, A_1, Q_1 represent the respective signs of the registers B, A, Q. Final result will be in AQ, which consist of $2n$-bits. (Here each register has n-bits).



Multiplication of Singed 2's complement data The straight forward multiplication will not work if either the multiplicand or the multiplier is negative. There are number of ways to perform multiplication of signed 2's complement data. One such a technique is *Booth's multiplication algorithm*. The following flowchart depicts about Booth's algorithm (see figure 7).

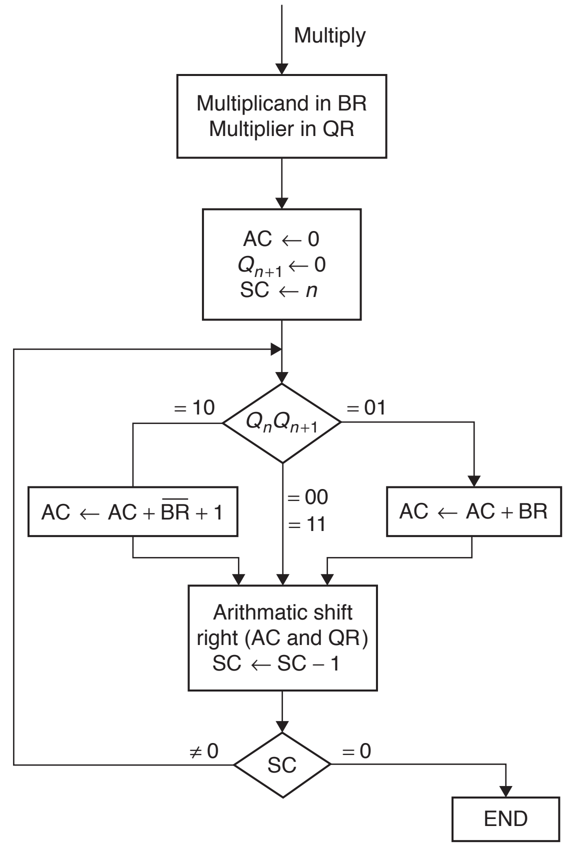


Figure 7 Booth's multiplication algorithm

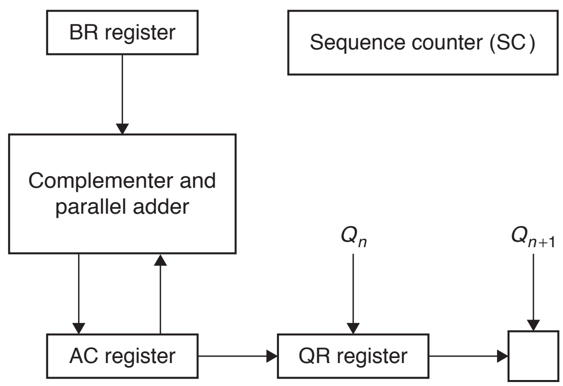
An additional 1-bit register placed logically to the right of the LSB(Q_n) of Q register designated Q_{n+1}.

Example 2: Multiply the two numbers −7 and +8 using booth's algorithm, using 5 bits.
BR = −7 = 11001
QR = +8 = 01000
Initially AC = 00000, Q_{n+1} = 0, SC = 5

$Q_n\,Q_{n+1}$	**BR** = **11001** $\overline{\textbf{BR}}+1 = 00111$	**AC**	**QR**	Q_{n+1}	**SC**
	Initial	00000	01000	0	5
00	ashr(AC and QR)	00000	00100	0	4
00	ashr(AC and QR)	00000	00010	0	3
00	ashr(AC and QR)	00000	00001	0	2
10	subtract BR ashr(AC and QR)	00000 <u>00111</u> 00111 00011	 10000	 1	 1
01	add BR ashr(AC and QR)	00011 <u>11001</u> 11100 11110	 10000 01000	 1 0	 1 0

∴ Result = 1111001000 = –56

Hardware implementation for Booth's algorithm:



Note: These two multiplication algorithms are sequential but we can also do the operation by means of a combinational circuit that forms the product bits all at once. The circuit consist of AND gates and adders.

Division algorithms

Division of signed magnitude data: Division of signed magnitude data is a process of successive compare, shift and subtract operations.

Example:
Dividend = 0111000000
Divisor = 10001

```
10001) 0111000000 (11010
       –10001
        010110
        –10001
         0010100
          –10001
           000110
```

Hardware implementation:

- The hardware implementation of division is same as multiplication, instead of shifting the divisor to the right, the dividend or partial remainder is shifted to the left, thus leaving the two numbers in the required relative position.
- The divisor is stored in the B register and the double-length dividend is stored in registers A and Q. The dividend is shifted to the left and the divisor is subtracted by adding its 2's complement value. The information about the relative magnitude is available in E.
- If $E = 1$, it signifies that $A \geq B$. A quotient bit 1 is inserted into Q_n and the partial remainder is shifted to the left to repeat the process.
- If $E = 0$, it signifies that $A < B$ so the quotient is Q_n remains a 0. The value of B is added to restore the partial remainder in A to its previous value. The partial remainder is shifted to the left and the process is repeated again until all quotient bits are formed.
- Finally, the quotient is in Q and remainder is in A. This method is called *restoring method*.

Divide overflow:

- A divide overflow condition occurs if the high-order half bits of the dividend constitute a number greater than or equal to the divisor.
- A division by zero must be avoided.

Other algorithms for division: Two other methods are available for dividing numbers:

Comparison method: To divide the two numbers A and B in comparison method, they are compared prior to the subtraction operation. If $A \geq B$, B is subtracted from A. If $A < B$ nothing is done. The partial remainder is shifted left and the numbers are compared again.

Non-restoring method: To divide two numbers A and B is non-restoring method, B is not added if the difference is negative but instead, the negative difference is shifted left and then B is added.

Floating-point Arithmetic Operations

Floating-point representation

Fixed-point representation allows representation of numbers with fractional component as well. But this approach has limitations. It is not possible to represent very large numbers and very small numbers in fixed point representation.

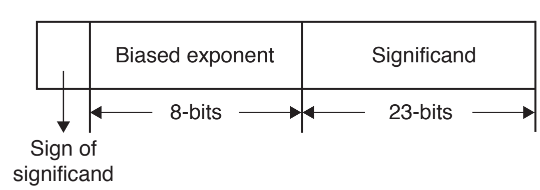
In floating-point representation, the numbers can be represented in the form,

$\pm S \times B^{\pm E}$

The three fields are
Sign: plus or minus
Significand: S
Exponent: E
are stored in a binary word.

The base B is implicit and need not be stored because it is same for all the numbers. It is assumed that the radix point is to the right of the left most or most significant bit of the significand, i.e., there is one bit to the left of the radix point.

32-bit floating-point format: The left most bit stores the sign of the number. The exponent value is stored in next 8-bits. This is represented in biased representation.



Biased representation: In biased representation, a fixed value, called the bias, is subtracted from the exponent field to get the true exponent value.

Bias = $(2^{k-1} - 1)$, where k = number of bits in binary exponent. In IEEE 32-bit floating point representation, bias $= 2^7 - 1 = 127$.

And the range of true exponents is −127 to +128.

The advantage of biased representation is that non-negative floating point numbers can be treated as integers for comparison purposes.

The last portion of word is the siginificand.

Normalized numbers:

- To simplify operation on floating point numbers, it is typically required that they must be normalized.
- A normalized number is one in which the most significant digit of significand is non-zero.
- For base-2 representation, a normalized number is therefore one in which the MSB of the significand is one.
- Normalized non-zero number is one in the form $\pm 1.bbb\cdots b \times 2^{\pm E}$, where b is either binary digit 0 or 1.
- As the MSB is always one, it is unnecessary to store this bit. Thus the 23-bit field is used to store a 24-bit significand with a value in the half open internal (1, 2).
- A number may be normalized by shifting the radix point to the right of the leftmost 1 bit and adjusting the exponent accordingly.

Example: In 32-bit floating representation of $-1.6328125 \times 2^{-20}$,

Sign = 1 (as the number is negative)

$(.6328125)_{10} = (.1010001\ldots)_2$

Exponent = −20

Biased exponent = 127 − 20 = 107

= 1101011

$\therefore -1.6328125 \times 2^{-20}$

= 1 01101011 10100010000000000000000

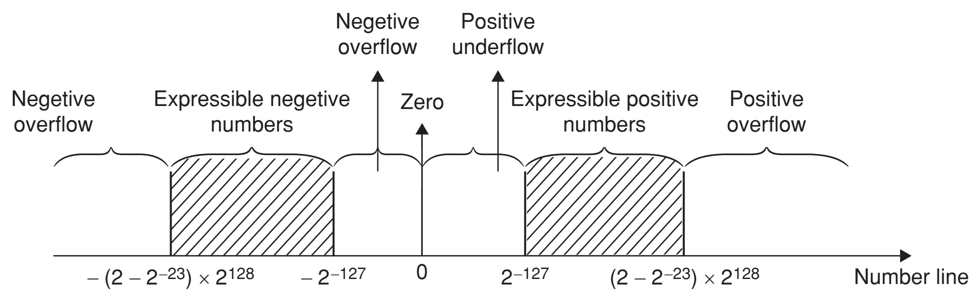


Figure 8 Range of expressible numbers in a 32-bit floating point format

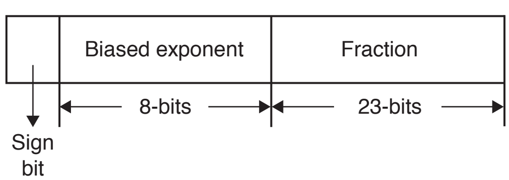
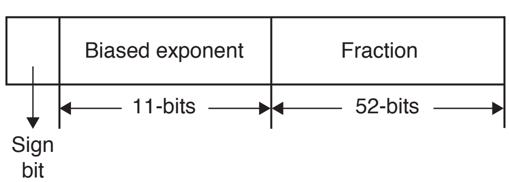
IEEE standard for binary floating-point representation



Single precision format



Double precision Format

Floating-point arithmetic

(i) Addition and subtraction: The algorithm consists the following phases:

1. Check for zeros
2. Align the significands/mantissas
3. Add or subtract the significands
4. Normalize the result

Example:

$(123 \times 10^0) + (234 \times 10^{-2})$

$= 123 \times 10^0 + 2.34 \times 10^0 = 125.34 \times 10^0$

(ii) Multiplication: The steps to multiply two floating point numbers are

1. Check for zeros
2. Add the exponents
3. Multiply the significands
4. Normalize the result

(iii) Division: The steps to divide two floating point numbers are

1. Check for zeros
2. Initialize registers and evaluate the sign
3. Align the dividend
4. Subtract the exponents
5. Divide the significands

Binary-Coded Decimal (BCD) Arithmetic Operations

Computers capable of performing decimal arithmetic must store the data in binary-coded form.

Example: BCD of 239 = 0010 0011 1001

BCD addition

In BCD each digit do not exceed 9, so the sum of two BCD digits cannot be greater than 9 + 9 + 1 = 19, the 1 in the sum being an input carry. When the binary sum of two BCD digits is greater than 1001, we obtain a non-valid BCD representation. The addition of binary 6 (0110) to the binary sum converts it to the correct BCD representation and also produces an output carry as required.

Example:

239 = 0010 0011 1001
426 = 0100 0010 0110
665   0110 0101 1111 >1001
            0110
              0110 0110 0101
         = 665

BCD subtraction

- Perform the subtraction by taking the 9's or 10's complement of the subtrahend and adding it to the minuend.
- The 9's complement of a decimal digit represented in BCD can be obtained by complementing the bits in the coded representation of the digit, provided a correction is included.

There are two possible correction methods:

1. Binary 1010 is added to each complemented digit and the carry discarded after each addition.

Example:

9's complement of 7 = 2
7 in BCD = 0111.
Complement of 7 = 1000
Add 1010 = 1010
1] 0010 = 2
↑
Discard

2. Binary 0110 is added before the digit is complemented.

Example:

BCD of 7 = 0111
Add 0110 = 0110
1101
Complement = 0010 = 2

Example 4: Which of the following multiplier bit pattern of Booth's multiplication algorithm gives worst case performance?

(A) 01010101….0101
(B) 000000….0000
(C) 11111111….1111
(D) 011110111110….01110

Solution: (A)

Booth's multiplication algorithm works well with consecutive 0's or 1's. But it gives worst case performance when the multiplier consists of alternative 0's and 1's. (As 01, 10 pattern leads to addition and subtractions).

Example 5: Consider the following 32-bit floating point representation scheme as shown in the format below:

Sign	Fraction	Exponent
← 1 →	← 24 →	← 7 →

A value is specified by three fields:
Sign field: 1 bit (0 for positive and 1 for negative values)
Fraction: 24-bits (with binary point being at the left end of fraction bits)
Exponent: 7-bits (in excess-64 signed integer representation)
The base of exponentiation is 16. The sign bit is in MSB. Then the normalized floating point representation of − 6.5 is

(A) E8000042 (B) E1000012
(C) D8000841 (D) D0000042

Solution: (D)

Here sign = 1 as the number is negative.
$(-6.5)_{10} = (-0110.1)_2$
$= (-1.101 \times 2^2)$
Fraction = 101000000000000000000000
Exponent = Excess − 64 exponent
= 64 + 2 = 66 = 1000010
$\therefore (-6.5)_{10}$
= 1 1010000000000000000000001000010
= D0000042.

Data Path

Data path consists of the components of the processor that performs arithmetic operations.

Components of data path: ALU is just one data path building block. Other components are

1. Computational Components, which consist of combinational circuits (output follow inputs)

Example: ALU.

2. State components, which consists of sequential circuits (output changes on clock edge)

Example: Registers.

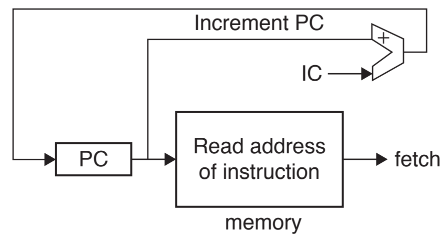
Example: The sequence of steps for the addition of two registers content are

1. $R1_{out}$, X_{in}
2. $R2_{out}$, Choose X, ADDITION, Y_{in}
3. Y_{out}, $R3_{in}$

(Each step executed in a single clock cycle).

- Data path and control unit forms the processing unit of a computer. The Data path includes ALU, multiplexers, all registers (like PC, IR) etc.

Example Data Path Design:

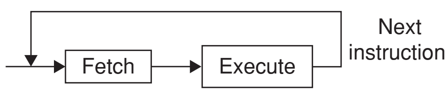


CPU Control Design

Instruction Cycle

A program residing in the memory unit of the computer consists of a sequence of instructions. The program is executed in the computer by going through a cycle for each instruction. Each instruction cycle in turn is subdivided into a sequence of sub cycles. For example, the phases of instruction cycle may be

1. Fetch
2. Decode
3. Read effective address
4. Execute, etc.



Instruction cycle

The cycle will be repeated, till all the instructions are executed.

Each phase is made up of more fundamental operations, called micro-operations.

Example micro-operations: Transfer between registers, simple ALU operation, etc.

Control Unit

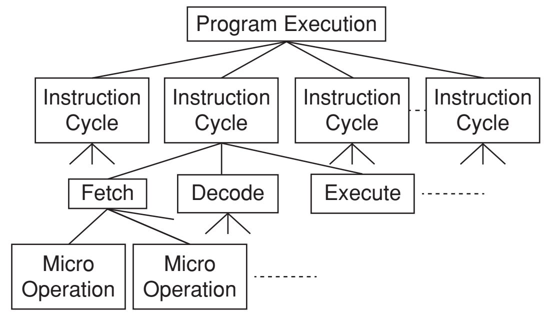
The control unit of a processor performs two tasks:

1. It causes the processor to execute micro-operations in the proper sequence, determined by the program being executed.
2. It generates the control signals that cause each micro-operation to be executed.

We now discuss the micro-operations of various phases of instruction cycle.

Micro-operation

- These are the functional or atomic operations of a processor.



Fetch Cycle: 'Fetch' stage of an instruction occurs at the beginning of each instruction, which causes an instruction to be fetched from memory. The micro-operations involved in fetch phase are

t_1: MAR ← PC (move contents of PC to MAR)
t_2: MBR← memory; PC ← (PC) + I (move contents of MAR location to MBR and increment PC by I)
t_3: IR← (MBR) · (move contents of MBR to IR)

Here *I* is instruction length.
Each micro-operation can be performed within the time of a single time unit.

Execute Cycle: For a machine with *N* different opcodes, there will be *N* different sequence of micro-operations. For the execution of following instruction.
Add R_1, X, the micro-operations will be

t_1: MAR← (IR(Address))
t_2: MBR← memory
t_3: $R_1 \leftarrow (R_1) + (\text{MBR})$

Control of the Processor

(i) Functional requirements of control unit: Let us consider the following concepts to the characterization of a CU.

1. Define the basic elements of the processor.
2. Describe the micro-operations that the processor performs.
3. Determine the functions that the control unit must perform to cause the micro-operations to be performed.

(ii) Basic elements of processor:
- ALU
- Registers
- Internal data path: Used to move data between registers and between register and ALU.
- External data path: Used to link registers to memory and *input–output* modules, often by means of a system bus.
- Control unit: Causes operations to happen within the processor.

(iii) Micro-operations of processor:
- Transfer data from one register to another.
- Transfer data from a register to an external interface.

- Transfer data from an external interface to a register.
- Perform an arithmetic or logic operation, using registers for input and output.

(iv) Control unit tasks:

- **Sequencing:** The control unit causes the processor to step through a series of micro-operations in the proper sequence, based on the program being executed.
- **Execution:** The control unit causes each micro-operation to be executed.

(v) Control signals: For the control unit to perform its function, it must have inputs that allow it to determine the state of the system and outputs that allows it to control the behaviour of the system. These are external specifications of the control unit.

Internally, the control unit must have the logic required to perform its sequencing and execution functions.

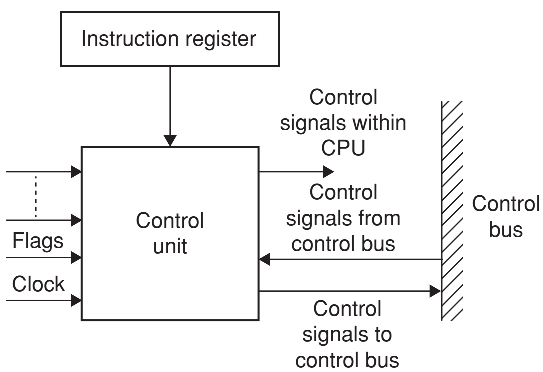


Figure 9 Block diagram of control unit

(a) Clock: This is how the control unit 'keeps time.' The control unit causes one micro-operation to be performed for each clock pulse. This is referred as processor cycle time or clock cycle time.

(b) Instruction registers: The opcode of current instruction is used to determine which micro-operations to perform during the execute cycle.

(c) Flags: Used to determine the status of the processor and outcome of previous ALU operations.

(d) Control signals from control bus: The control bus portion of system bus provides signals to the control unit.

(e) Control signals within the processor:

1. Those that cause data to be moved from register to another.
2. Those that activate specific ALU functions.

(f) Control signals to control bus:

1. Control signals to memory.
2. Control signals to input–output modules.

Totally, there are three types of control signals:

1. Those that activate ALU function.
2. Those that activate a data path.
3. Those that are signals on the external system bus.

Functions of Control Unit

- The control unit directs the entire computer system to carry out stored program instructions.
- The control unit must communicate with both the Arithmetic Logic Unit and Main memory.
- The control unit instructs the arithmetic logic unit by which, logical or arithmetic operation is to be performed.
- The control unit coordinate the activities of the other two units as well as all peripheral and auxiliary storage devices linked to the computer.

Design of Control Unit

Control unit generates control signals using one of the two organizations

(1) Hardwired control unit
(2) Micro-programmed control unit.

Hardwired control unit

- It is implemented as logic circuits (gates, flip-flops, decoders, etc.) in the hardware.
- It is very complicated if we have a large control unit.
- In this organization, if the design has to be modified or changed. It requires changes in wiring among the various components. Thus the modification of all the combinational circuits may be very difficult.

Architecture of hardwired control unit An example hardwired control unit is shown in Figure 9.

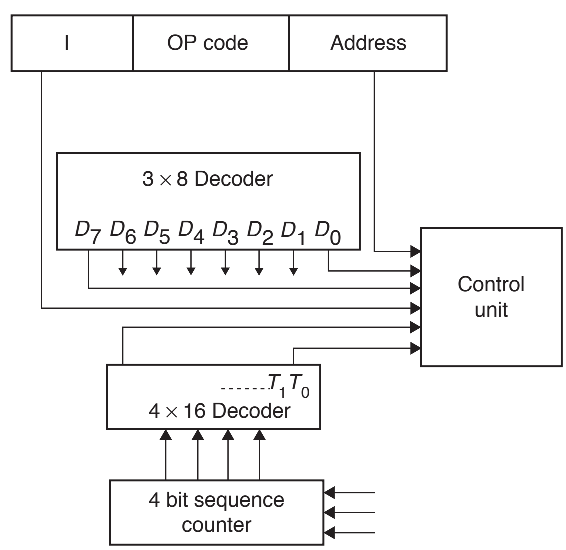

Figure 10 Hardwired control unit

The above control unit consists of:

- Instruction Register
- Number of control logic gates

- Two decoders
- 4-bit sequence counter.
- An instruction read from memory is placed in the instruction register (IR)
- The instruction register is divided into three parts: the *I* bit, operation code and Address part.
- First 12-bits (0-11) to specify an address, next 3-bits specify the operation code (op code) field of the instruction and last left most bit specify the addressing mode *I*.
  $I = 0$ for direct address
  $I = 1$ for indirect address
- First 12-bits are applied to the control logic gates.
- The Opcode bits (12-14) are decoded with 3×8 decoder.
- The eight outputs (D_0 through D_7) from a decoder go to the control logic gates to perform specific operation.
- Last bit 15 is transferred to a *I* flip flop designated by symbol *I*.
- The 4-bit sequence counter SC can count in binary from 0 through15.
- The counter output is decoded into 16 timing pulses T_0 through T_{15}.
- The sequence counter can be incremented by INR input or clear by CLR input synchronically.

Advantages:

- Hardwired control unit is fast because control signals are generated by combinational circuits.
- The delay in generation of control signals depends upon the number of gates.

Disadvantages:

- More is the control signal required by CPU, more complex will be the design of control unit.
- Modifications in control signal are very difficult. That means it requires rearranging of wires in the hardware circuit.
- It is difficult to correct mistake in original design or adding new features.

Micro-programming control unit

- A micro-programmed Control unit is implemented using programming approach. A sequence of micro-operations are carried out by executing a program consisting of microinstructions.
- Micro-program, consisting of micro instructions is stored in the control memory of the control unit.
- Execution of micro-instruction is responsible for generation of a set of control signals.

A micro-instruction consists of:

- One or more micro-instructions to be executed.
- Address of next micro-instruction to be executed.

(a) Micro-operations: The operations performed on the Data stored inside the registers are called Micro-operations.

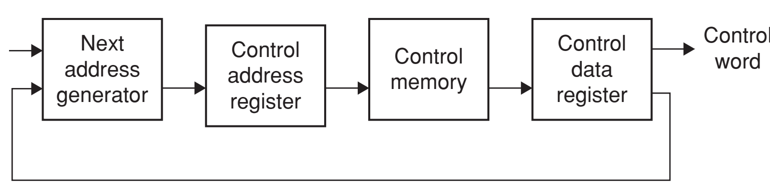
(b) Micro-programs: Micro-programming is the concept for generating control signals using programs. These programs are called Micro-programs.

(c) Micro-instructions: The instructions that make Micro-programs are called micro-instructions.

(d) Micro-code: Micro-program is a group of micro-instructions. Micro-program can also be termed as micro-code.

(e) Control memory: Micro-programs are stored in the read-only memory (ROM). That memory is called control memory.

(f) Architecture of Micro-Programmed Control Unit:



- The address of micro-instruction that is to be executed is stored in the control address register (CAR).
- Micro-instruction corresponding to the address stored in CAR is fetched from control memory and is stored in the control data register (CDR).
- This micro-instruction contains control word to execute one or more micro-operations.
- After the execution of all micro-operations of micro-instructions, the address of next micro-instructions is located.

Advantages:

- The design of micro-program control unit is less complex because micro-programs are implemented using software routines.
- The micro-programmed control unit is more flexible because design modifications, correction and enhancement is easily possible.
- The new or modified instruction set of CPU can be easily implemented by simply rewriting or modifying the contents of control memory.
- The fault can be easily diagnosed in the micro-program control unit using diagnostic tools by maintaining the contents of flags, registers and counters.

Disadvantages:

- The micro-program control unit is slower than hardwired control unit. That means to execute an instruction in micro-program control unit requires more time.

- The micro-program control unit is expensive than hardwired control unit in case of limited hardware resources.
- The design duration of micro-program control unit is more than hardwired control unit for smaller CPU.

Types of Micro-instructions

Micro-instructions can be classified as

Horizontal micro-instruction

- Individual bits in horizontal micro-instructions correspond to individual control lines.
- These are long and allow maximum parallelism since each bit controls a single control line.
- No decoding needed.

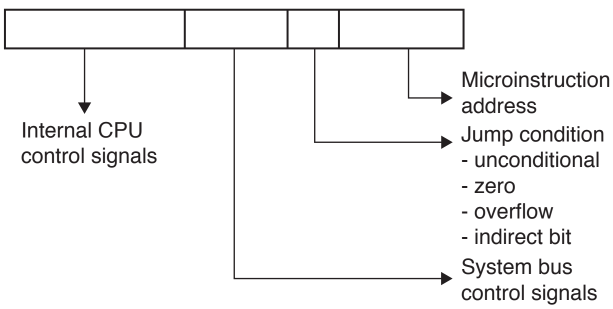


Figure 11 Horizontal micro-instruction format

Vertical micro-instruction

- Here, control lines are coded into specific fields within a micro-instruction.
- Decoders are needed to map a field of k-bits to 2^k possible combinations of control lines.

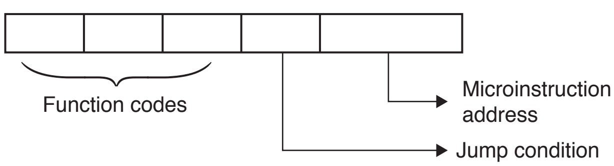

Figure 12 Vertical micro-instruction format

Example: A 3-bit field in a micro-instruction could be used to specify any one of eight possible lines.

- Hence these instructions are much shorter than horizontal ones.
- Control fields encoded in the same field cannot be activated simultaneously. Therefore vertical micro-instructions allow only limited parallelism.
- Decoding is necessary.

Micro-instruction Sequencing

Two concerns are involved in the design of a micro-instruction sequencing technique:

1. The size of micro-instruction: Minimizing size of control memory reduces the cost of that component.
2. The address-generation time:

A desire to execute micro-instructions as fast as possible. In executing a micro program, the address of next micro-instruction to be executed is in one of these categories.

1. Determined by IR
2. Next sequential address
3. Branch

Micro-instructions Execution

The Micro-instruction cycle has two parts:

1. Fetch
2. Execution

The effect of execution of a micro-instruction is to generate control signals. Some of the signals control points internal to the processor. The remaining signals go to the external control bus or other external interface.

Micro-instructions can be classified in a variety of ways.

1. Vertical/horizontal
2. Packed/unpacked
3. Hard/soft micro-programming
4. Direct/indirect encoding.

RISC and CISC

One of the important aspects of computer architecture is the design of the instruction set for the processor. The instruction set chosen for a particular computer determines the way that machine language programs are constructed. There are two categories of computers based on instructions:

1. Complex instruction set computer (CISC)
2. Reduced instruction set computer (RISC)

CISC: A computer with a large number of instructions is classified as a complex instruction set computer.

RISC: A computer which has fewer instructions with simple constructs, so they can be executed much faster with in the CPU without having to use memory as often. This type of computer is classified as RISC.

CISC characteristics

- CISC provides a single machine instruction for each statement, That is written in a high level language so that compilation process is simplified and the over all computer performance improved.
- It has variable length instruction formats.
- It provides direct manipulation of operands residing in memory.
- Some instructions that perform specialized tasks and are used infrequently.
- A large variety of addressing modes

Drawback of CISC architecture As more instructions and addressing modes are incorporated into a computer, the more hardware logic is needed to implement and support them and hence this causes the computations to slow down.

RISC characteristics

- Reduce execution time by simplifying the instruction set of the computer.
- Fewer numbers of instructions
- Relatively fewer addressing modes
- Memory access is limited to load and store instructions.
- All operations are done with in the register of the CPU.
- Fixed - length, easily decoded instruction format.
- Single-cycle instruction execution.
- Hardwired rather than micro-programmed control.
- Relatively large number of registers.
- Uses overlapped register windows to speed - up procedure call and return.
- Efficient instruction pipeline.
- Efficient translation of high - level language programs into machine language programs by the compiler.

Example 6: An instruction set of a processor has 200 signals which can be divided into 5 groups of mutually exclusive signals as follows.

Group 1: 30 Signals
Group 2: 90 Signals
Group 3: 20 Signals
Group 4: 10 Signals
Group 5: 50 Signals
How many bits of the control words can be saved by using vertical micro-programming over horizontal microprogramming?

(A) 27 (B) 173
(C) 200 (D) 227

Solution: Horizontal micro-programming requires 200 signals. But vertical micro-programming uses encoding. So

Group 1 requires 5-bits ($\because 2^5 = 32$)
Group 2 requires 7-bits ($\because 2^7 = 128$)
Group 3 requires 5-bits ($\because 2^5 = 32$)
Group 4 requires 4-bits ($\because 2^4 = 16$)
Group 5 requires 6-bits ($\because 2^6 = 64$)

$\therefore$ Total bits required using vertical micro programming = 27

$\therefore$ Number of bits saved = 200 – 27 = 173

Exercise

Practice Problems I

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Using two's complement arithmetic the resultant of 111100001111 – 110011110011 is
(A) 0010 0001 1111
(B) 0011 0000 1100
(C) 0010 0001 1101
(D) 0010 0001 1100

2. IEEE 32-bit floating point format of 384 is
(A) 0 10000111 00000000000000000000000
(B) 0 10000111 10000000000000000000000
(C) 0 00001000 00000000000000000000000
(D) 0 00001000 10000000000000000000000

3. Consider the following IEEE 32-bit floating point number:
0 01111110 10100000000000000000000.
What is the decimal value equivalent to given number?
(A) 0.25 (B) 3.25
(C) 0.8125 (D) 0.9375

4. What would be the bias value for a base-8 exponent in a 7-bit field?
(A) 8 (B) 16
(C) 63 (D) 64

5. The normalized value of the resultant of $8.844 \times 10^{-3} - 2.233 \times 10^{-1}$ is
(A) -2.144×10^{-1} (B) -0.2144
(C) -2×10^{-1} (D) -0.2

6. Which of the following is the correct sequence of micro-operations to add a number to the AC when the operand is a direct address operand and store the final result to AC?
(A) MAR←(IR(address))
MBR ← memory
$R_1 \leftarrow$ (AC) + (MBR)
(B) MAR ← IR(address)
MBR ← MAR
$R_1 \leftarrow$ (MBR)
$R_2 \leftarrow$ (AC) + (R_1)
AC ← R_2
(C) MAR ← (IR(address))
MBR ← Memory(MAR)
$R_1 \leftarrow$ (MBR)
$R_2 \leftarrow$ (AC) + (R_1)
AC ← (R_2)
(D) MAR ← (IR (address))
MBR ← Memory(MAR)
AC ← (AC) + (MAR)

Statement for linked answer questions 7 to 9: Assume that the control memory is 24 bits wide. The control portion of the micro-instruction format is divided into two fields. A micro-operation field of 13-bits specifies the micro-operation to be performed. An address selection field specifies a condition, based on the flags, that will cause a micro-instruction branch. There are eight flags.

7. How many bits are there in address selection field?
(A) 1 (B) 2
(C) 3 (D) 4

8. How many bits are there in address field?
(A) 8 (B) 9
(C) 13 (D) 24

9. What is the size of control memory in bits?
(A) 256 (B) 768
(C) 3328 (D) 6144

10. A simple processor has 3 major phases to its instructions cycle:
1. Fetch
2. Decode
3. Execute

Two 1-bit flags are used to specify the current phase in hardwired implementation. Will these flags required in micro-programming also?
(A) Yes
(B) No
(C) Cannot predict
(D) Depends on clock cycle time

11. In a 3-bus data path, the micro instructions format will be Opcode src1, src2, desti; The number of operations supported are 8 and the src1, src2 and desti require 20, 16 and 20 bits respectively.
The total number of horizontal microinstructions specified will be
(A) 2^{64} (B) 2^{8}
(C) 2^{56} (D) 2^{61}

12. What is the smallest positive normalized number represented using IEEE single precision floating point representation?
(A) 2^{-128} (B) $1 - 2^{-127}$
(C) 2^{-127} (D) 2^{-126}

13. A micro program control unit is required to generate a total of 30 control signals. Assume that during any micro instruction, almost two control signals are active. Minimum number of bits required in the control word to generate the required control signals will be
(A) 2 (B) 2.5
(C) 10 (D) 12

14. What is the fraction field of the single-precision floating point representation of 6.25?
(A) 1110 1000 0000 0000 0000 000
(B) 1001 0000 0000 0000 0000 000
(C) 1100 0000 0000 0000 0000 000
(D) 0110 0100 0000 0000 0000 000

15. Let the total number of control signals generated are n, then what is the number of bits allocated in control field of vertical micro programming?
(A) $n/2$ (B) n
(C) 2^n (D) $\log_2^{\ n}$

16. In a micro programmed control unit, a control field of one address control instruction has to support two groups of control signals. In group1 it is required to generate either one or none of the 32 control signals. In group 2 at most 5 from the remaining, what will be the number of bits needed for the control field?
(A) 8 (B) 10
(C) 35 (D) 37

17. Assume that the exponent e is constrained to lie in the range $0 \leq e \leq x$, with a bias of q, that the base is b and that the significant is P-digits in length.
What is the largest positive value that can be written is normalized floating point?
(A) $b^{x-q}(1 - b^{-p})$ (B) b^{-q-1}
(C) b^{-q-p} (D) $b^{x-q}(b^{-p} - 1)$

18. By using Booth's Multiplication algorithm. Below two numbers are multiplied:
Multiplicand: 0111 0111 1011 1101
Multiplier: 0101 1010 1110 1110
How many additions/subtractions are required for the multiplication of the above two numbers?
(A) 8 (B) 10
(C) 13 (D) 7

19. Let us assume, we are multiplying two positive integers 1101 and 1011. The multiplicand M is 1101 and Multiplier Q is 1011. What is partial product after second cycle?
(A) 0110 1101 (B) 1001 1110
(C) 0100 1111 (D) 1000 1111

20. The decimal representation of the 2's complement number 1101011 is
(A) 21 (B) –21
(C) 219 (D) 91

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. A microprogrammed control unit
(A) is faster than a hard-wired control unit
(B) facilitates easy implementation of new instructions.
(C) is useful when very small programs are to be run.
(D) usually refers to the control unit of a micro-processor.

2. Micro-program is
(A) the name of a source program in micro computers.
(B) a primitive form of macros used in assembly language programming.
(C) a program of a very small size.
(D) the set of instruction indicating the basic elemental commands which directly control the operation of a system.

3. Programming that actually controls the path of signal or data within the computer is called
(A) System programming
(B) Micro-programming
(C) High-level language programming
(D) Assembly language programming

4. The instruction cycle time in a generic microprocessor is
(A) Longer than the machine cycle time
(B) Shorter than the machine cycle time
(C) Same as the machine cycle time
(D) Double the machine cycle time

5. Microprocessor unit or central processor unit consist of
(A) Control circuitry (B) ALU
(C) Memory (D) All of these

6. The exponent of a floating point number is represented in excess-N code so that
(A) the dynamic range is large
(B) overflow is avoided
(C) the precision is high
(D) the smallest number is represented efficiently

7. Using Booth's algorithm for Multiplication, the Multiplier −14 is coded as
(A) 11110 (B) 01110
(C) 10010 (D) 00010

8. Data Path consists of
(A) Registers (B) ALU
(C) Bus (D) All of these

9. A floating point number that has a '0' in MSB of mantissa is said to have ____
(A) Overflow (B) Underflow
(C) Normalization (D) Positive exponent

10. Let the Binary sum after BCD addition is stored in K, Z_8, Z_4, Z_2, and Z_1 Then the condition for a correction and output carry can be expressed as $C =$
(A) $K + Z_8 Z_4 + Z_8 Z_2$ (B) $K + Z_8 Z_4 + Z_4 Z_2$
(C) $K + Z_8 Z_2 + Z_8 Z_1$ (D) $K + Z_4 Z_2 + Z_2 Z_1$

11. Which of the following is an advantage of biased exponents?
(A) Convenient way to represent exponents
(B) Useful for conversion
(C) Convenient for comparison purposes
(D) All of these

12. Booth multiplication skips over runs of zeros and ones which reduces the number of add and subtract steps needed to multiply two n-bit numbers to n to a variable number whose average value n_{avg} is less than n what will be n_{avg}?
(A) $n/3$ (B) $n/4$
(C) $n/2$ (D) n

13. The sequence of events that happen during a fetch operation is:
(A) PC → memory → IR
(B) PC → MAR → memory → IR
(C) PC → MAR → memory → MDR → IR
(D) PC → memory → MDR → IR

14. Micro-programming is a technique for
(A) Programming input or output routines
(B) Programming the microprocessors
(C) Programming the control steps of a computer
(D) Writing small programs

15. In a micro program ____ specifies the address of Micro-instructions to be executed.
(A) AR (B) PC
(C) SP (D) CAR

16. Which one of the following statements is correct?
(A) Micro-programmed control unit is costlier and slow.
(B) Micro-programmed control unit are cheap and slow.
(C) Micro-programmed control unit is costlier and fast.
(D) Micro-programmed control unit are fast and cheaper.

17. Horizontal micro-instructions have
(A) High degree parallelism, more encoding of control information.
(B) High degree parallelism, little encoding of control information.
(C) Low degree parallelism, more encoding of control information.
(D) Low degree parallelism, little encoding of control information.

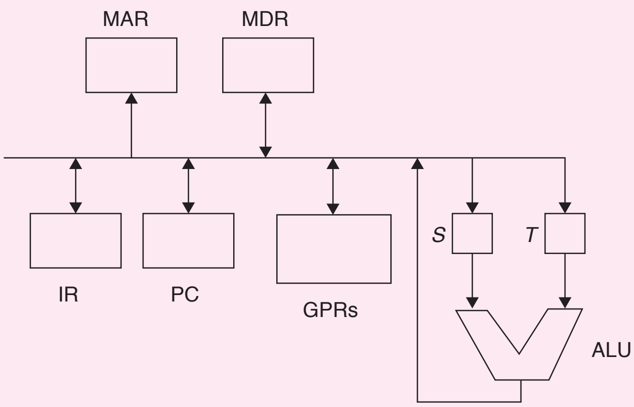
18. A vertical micro-instruction have ____.
(A) Short formats and considerable encoding of control information
(B) Long formats and considerable encoding of control information
(C) Short formats and little encoding of control information
(D) Long formats and little encoding of control information

19. Guard bits are used to
(A) avoid unnecessary loss of MSB
(B) avoid unnecessary loss of LSB
(C) the loss of MSB
(D) the loss of LSB

20. Which of the following is not the essential element of a number represented in floating-point notation?
(A) Exponent (B) Significand
(C) Sign (D) Normalization

Previous Years' Questions

Common data for questions 1 and 2: Consider the following data path of a CPU.



The ALU, the bus and all the registers in the data path are of identical size. All operations including incrementation of the PC and the GPRs are to be carried out in the ALU. Two clock cycles are needed for memory read operation—the first one for loading address in the MAR and the next one for loading data from the memory bus into the MDR.

1. The instruction 'add R_0, R_1' has the register transfer interpretation $R_0 \leftarrow R_0 + R_1$. The minimum number of clock cycles needed for execution cycle of this instruction is
   (A) 2 (B) 3
   (C) 4 (D) 5

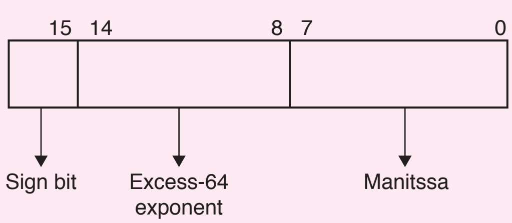
2. The instruction 'call *Rn*, sub' is a two word instruction. Assuming that PC is incremented during the fetch cycle of the first word of the instruction, its register transfer interpretation is

   $Rn \leftarrow$ PC + 1;

   PC $\leftarrow$ M[PC]

   The minimum number of CPU clock cycles, needed during the execution cycle of this instruction is
   (A) 2 (B) 3
   (C) 4 (D) 5

Data for question 3: Consider the following floating-point format.



Mantissa is a pure fraction in sign-magnitude form.

3. The normalized representation for the above format is specified as follows. The mantissa has an implicit 1 preceding the binary (radix) point. Assume that only 0's are padded in while shifting a field.

   The normalized representation of the above number (0.239×2^{13}) is: **[2005]**
   (A) 0*A* 20 (B) 11 34
   (C) 49 *D*0 (D) 4*A E*8

4. In the IEEE floating point representation the hexadecimal value 0*x*00000000 corresponds to **[2008]**
   (A) The normalized value 2^{-127}
   (B) The normalized value 2^{-126}
   (C) The normalized value + 0
   (D) The special value + 0

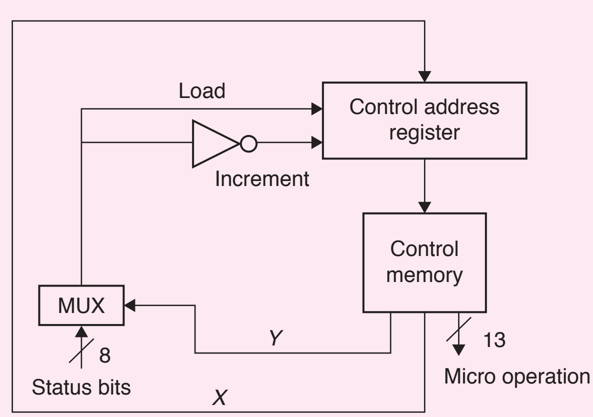
5. *P* is a 16-bit signed integer. The 2's complement representation of *P* is $(F87B)_{16}$. The 2's complement representation of 8**P* is **[2010]**
   (A) $(C3D8)_{16}$ (B) $(187B)_{16}$
   (C) $(F878)_{16}$ (D) $(987B)_{16}$

6. The decimal value 0.5 in IEEE single precision floating point representation has **[2012]**
   (A) fraction bits of 000 … 000 and exponent value of 0
   (B) fraction bits of 000…000 and exponent value of –1
   (C) fraction bits of 100…000 and exponent value of 0
   (D) no exact representation

7. The smallest integer that can be represented by an 8-bit number in 2's complement form is **[2013]**
   (A) –256 (B) –128
   (C) –127 (D) 0

8. Let *A* = 1111 1010 and *B* = 0000 1010 be two 8-bit 2's complement numbers. Their product in 2's complement is **[2004]**
   (A) 1100 0100 (B) 1001 1100
   (C) 1010 0101 (D) 1101 0101

9. The microinstructions stored in the control memory of a processor have a width of 26 bits. Each microinstruction is divided into three fields, a micro-operation field of 13 bits, a next address field (*X*), and a MUX select field (*Y*), there are 8 status bits in the inputs of the MUX **[2004]**



How many bits are there in the X and Y fields, and what is the size of the control memory in number of words?

(A) 10, 3, 1024 (B) 8, 5, 256
(C) 5, 8, 2048 (D) 10, 3, 512

10. Consider the following sequence of micro-operations.

MBR ← PC
MAR ← X
PC ← Y
Memory ← MBR

Which one of the following is a possible operation performed by this sequence? **[2013]**

(A) Instruction fetch
(B) Operand fetch
(C) Conditional branch
(D) Initiation of interrupt service

11. For computers based on three-address instruction formats, each address field can be used to specify which of the following: **[2015]**

(S_1) A memory operand
(S_2) A processor register
(S_3) An implied accumulator register

(A) Either S_1 or S_2
(B) Either S_2 or S_3
(C) Only S_2 and S_3
(D) All of S_1, S_2 and S_3

12. Let X be the number of distinct 16 - bit integers in 2's complement representation. Let Y be the number of distinct 16 - bit integers in sign magnitude representation. They $x - y$ is ______ . **[2016]**

13. The n-bit fixed-point representation of an unsigned real number X uses f bits for the fraction part. Let $i = n - f$. The range of decimal values for X in this representation is **[2017]**

(A) 2^{-f} to 2^i (B) 2^{-f} to $(2^i - 2^{-f})$
(C) 0 to 2^i (D) 0 to $(2^i - 2^{-f})$

14 Consider the C code fragment given below.

```
typedef struct node  {
  int data;
  node* next;
}   node;
void join (node* m, node* n)  {
    node* p = n;
    while (p - >next != NULL)  {
      p = p - >next;
    }
    p - >next = m;
}
```

Assuming that m and n point to valid NULL-terminated linked lists, invocation of join will **[2017]**

(A) append list m to the end of list n for all inputs.
(B) either cause a null pointer dereference or append list m to the end of list n.
(C) cause a null pointer dereference for all inputs.
(D) append list n to the end of list m for all inputs.

15. The representation of the value of a 16-bit unsigned integer X in hexadecimal number system is BCA9. The representation of the value of X in octal number system is **[2017]**

(A) 571244 (B) 736251
(C) 571247 (D) 136251

16. Consider the following processor design characteristics.

I. Register-to-register arithmetic operations only
II. Fixed-length instruction format
III. Hardwired control unit

Which of the characteristics above are used in the design of a RISC processor? **[2018]**

(A) I and II only (B) II and III only
(C) I and III only (D) I, II and III

17. Consider the unsigned 8-bit fixed point binary number representation below:

$$b_7\, b_6 b_5 b_4\, b_3 \cdot b_2\, b_1\, b_0$$

where the position of the binary point is between b_3 and b_2. Assume b_7 is the most significant bit. Some of the decimal numbers listed below cannot be represented exactly in the above representation:

(i) 31.500 (ii) 0.875
(iii) 12.100 (iv) 3.001

Which one of the following statements is true? **[2018]**

(A) None of (i), (ii), (iii), (iv) can be exactly represented
(B) Only (ii) cannot be exactly represented
(C) Only (iii) and (iv) cannot be exactly represented
(D) Only (i) and (ii) cannot be exactly represented

Chapter 3

Memory Interface, I/O Interface

LEARNING OBJECTIVES

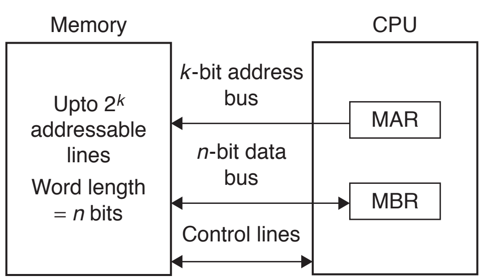
- *Memory interface*
- *RAM*
- *ROM*
- *Memory interfacing*
- *Input–output interfacing*
- *Handshaking*
- *Data transfer mode*
- *Design techniques for interrupts*
- *Direct memory access*
- *Input–output processor*

Memory Interface

Basic Concepts

Computer memory is used to store programs and data. The maximum size of a memory that can be used in any computer is determined by the addressing scheme.

Example: If the memory address has 16-bits, then the size of memory will be 2^{16} Bytes.



If MAR is k-bits long and MDR is n-bits long, then the memory may contain up to 2^k addressable locations and the n-bits of data are transferred between the processor and memory. This transfer takes place over processor bus. The processor bus has

1. Address line
2. Data line
3. Control line

Control line is used for coordinating data transfer.

Processor reads the data from the memory by loading the address of the required memory location into MAR and setting the $R/\overline{W}$ line to 1.

The memory responds by placing the data from the addressed location onto the data lines and confirms the actions. Upon confirmation, the processor loads the data onto the data lines, into MDR register. The processor writes the data into the memory location by loading the address of this location into MAR and loading the data into MDR sets the $R/\overline{W}$ line to 0.

- **Memory Access Time:** It is the time that elapses between the initiation of an operation and the completion of that operation.
- **Memory Cycle Time:** It is the minimum time delay that required between the initiations of two successive memory operations.

RAM (Random Access Memory)

In RAM, if any location that can be accessed for a read/write operation in fixed amount of time, it is independent of the location's address:

- Memory cells are usually organized in the form of array, in which each cell is capable of storing one bit of information.
- Each row of cells constitutes a memory word and all cells of a row are connected to a common line called as word line.
- The cells in each column are connected to sense/write circuit by two bit lines.

The data input and data output of each sense/write circuit are connected to a single bidirectional data line that can be connected to a data bus.

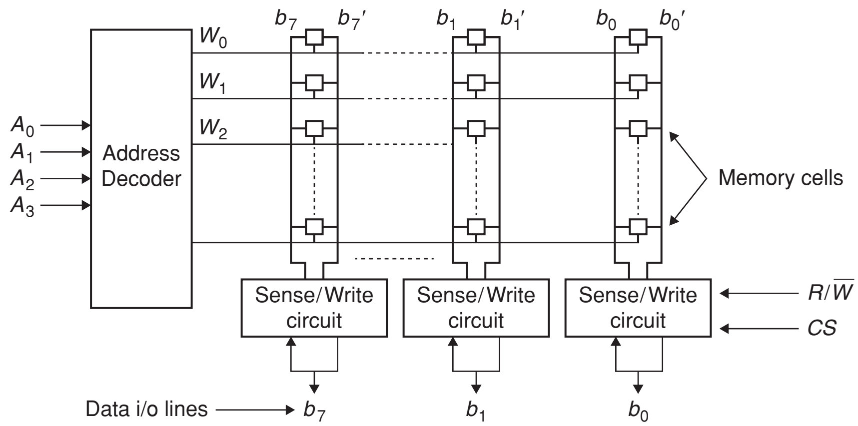


Figure 1 Organization of bit cells in a memory chip

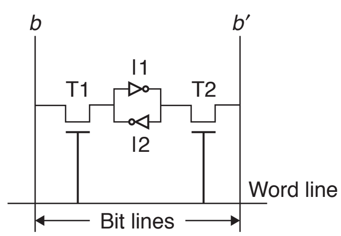
- $R/\overline{W}$: Specifies the required operation.
- CS: Chip select input selects a given chip in the multi-chip memory system.

Static memories

Memories that consist of circuits capable of retaining their state as long as power is applied are known as static memories.

SRAM (static RAM) SRAM consists of two inverters, two transistors. In order to read the state of the SRAM cell, the word line is activated to close switches T1 and T2.



Advantages of SRAM:

1. It has low power consumption, because the current flows in the cell only when the cell is being activated or accessed.
2. SRAM can be accessed quickly.

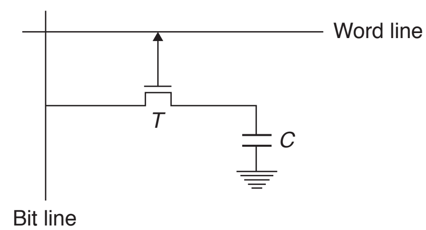
Disadvantages of SRAM: SRAMs are said to be volatile memories, because their contents are lost when the power is interrupted.

DRAM (Dynamic RAM) Less expensive RAMs can be implemented if simplex cells are used, such cells cannot retain their state indefinitely. Hence they are called dynamic RAMs.

The information stored in a dynamic memory cell in the form of a charge on a capacitor and this charge can be maintained only for tens of milliseconds.

The contents must be periodically refreshed by restoring the capacitor charge to its full value.

Example: Single-transistor dynamic memory cell:



If charge on capacitor > threshold value, then bit line will have ‘1’. If charge on capacitor < threshold value, then bit line will have ‘0’.

DRAM	SRAM
1. Volatile	1. Volatile
2. Simple to build and slower than SRAM	2. Faster than DRAM
3. Need refresh circuitry	3. More expensive to build
4. Favoured for large memory units	4. Favoured for cache memory

Latency It is the amount of time it takes to transfer a word of data to or from the memory.

- For the transfer of a single word, the latency provides the complete indication of memory performance.
- For a block transfer, the latency denotes the time it takes to transfer the first word of data.

Bandwidth It is defined as the number of bits or bytes that can be transferred in one second.

Note: All dynamic memories have to be refreshed.

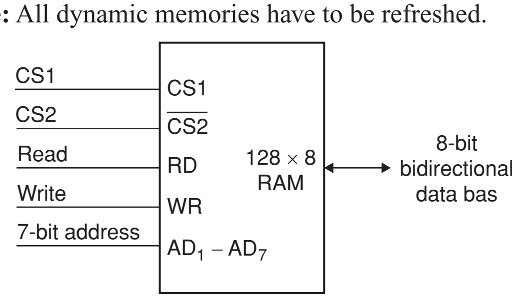


Figure 2 RAM chip block diagram

Read-only Memory (ROM)

Both SRAM and DRAM chips are volatile, which means that they lose the stored information if power is turned off. If the normal operation involves only reading of stored data, use ROM memory.

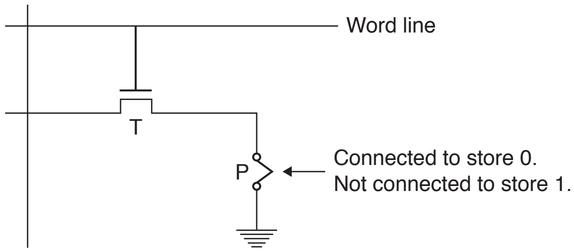

Figure 3 ROM cell

Types of ROM

Different types of non-volatile ROM are:

1. **PROM (Programmable ROM):**
   - Allows the data to be loaded by the user.
   - Less expensive, faster, flexible.
2. **EPROM (Erasable PROM):**
   - Allows the stored data to be erased and new data to be loaded.
   - Flexible, retain information for a long time.
   - Contents erased by UV light.
3. **EEPROM (Electrically Erasable PROM):**
   - Programmed and erased electrically.
   - Allows the erasing of all cell contents selectively.
   - Requires different voltage for erasing, writing and reading of stored data.
4. **Flash memory:** Allows to read the contents of a single cell but it is only possible to write the entire contents of a block.

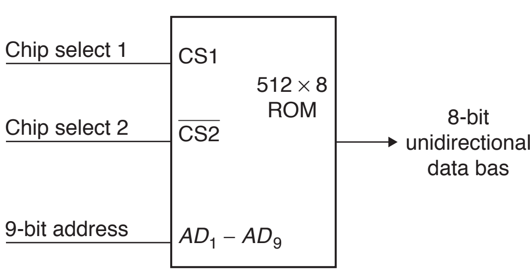

Figure 4 Block diagram of ROM chip

Memory Interfacing

The interfacing circuit enables the access of processor to memory. The function of memory interfacing is that the processor should be able to read from and write into a given register of a memory chip. To perform this, the microprocessor should be

1. able to select the chip.
2. identify the register.
3. enable the appropriate buffer.

Input–output Interfacing

Basic Concepts of I/O Module

I/O module contains logic for performing a communication function between the peripherals and the bus. The peripherals are not connected to the system bus directly. The reasons for this are

1. Peripherals are electromechanical and electromagnetic devices and their manner of operation is different from the operation of the CPU and memory, which are electronicdevices. So a conversion of signal values may be required.
2. The data transfer rate of peripherals is usually slower than the transfer rate of the CPU and hence a synchronization mechanism may be needed.
3. Data codes and formats in peripherals differ from the word format in the CPU and memory.
4. The operating modes of peripherals are different from each other and each must be controlled so as not to disturb the operation of other peripherals connected to the CPU.

To resolve these differences, computer systems include special hardware components between the CPU and peripherals to supervise and synchronize all input and output transfers. These components are called 'interface' units.

By using this interfacing,

1. interface to the processor and memory via the system bus or central switch.
2. interface to one or more peripheral devices by tailored data links.

Input–output devices

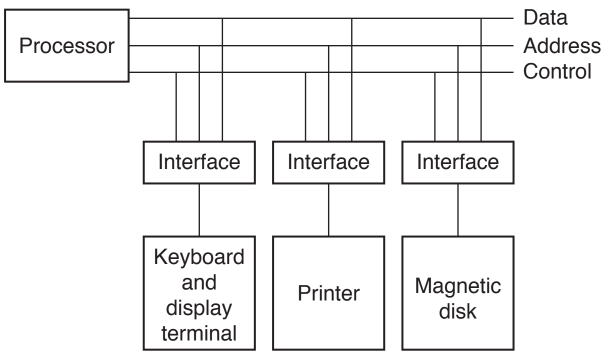
- Input and Output devices provide a means for people to make use of a computer.
- Some I/O devices function as an interface between a computer system and other physical system.

Input–output interface

Input/output Interface provides a method for transferring information between internal storage (such as memory and CPU Register) and external I/O devices. It resolves the difference between the computer and peripheral devices.

Input–output bus and interface modules

Each peripheral has an interface module associated with it. The interface module decodes the device address (device code), decodes signals for the peripheral controller, synchronizes the data flow and supervises the transfer rate between peripheral and CPU or memory.



Function of buses

1. **Memory bus:** It is used for information transfer between CPU and main memory.
2. **I/O bus:** It is used for information transfers between CPU and I/O devices through their I/O interface.

Isolated versus memory mapped I/O

1. **Isolated I/O:**
   - Separate I/O read/write control lines in addition to memory read/write control lines.
   - Separate (isolated) memory and I/O address space
   - Distinct input and output instructions.
2. **Memory-mapped I/O:**
   - A single set of Read/write control lines (i.e., no distinction between memory and I/O transfer).
   - Memory and I/O address share the common address space (reduces memory address range available).
   - No specific input or output instruction.
   - The same memory reference instructions can be used for I/O transfer.
   - Considerable flexibility in handling I/O operations.

Asynchronous serial transfer

In serial data transmission, each bit in the message is sent in sequence one at a time. Serial transmission can be synchronous or asynchronous.

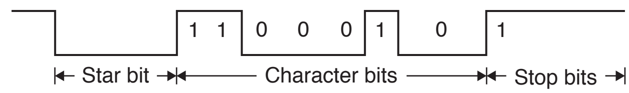
In synchronous transmission, the two units share a common clock frequency and bits are transmitted continuously at the rate dictated by the clock pulses.

In asynchronous transmission, binary information is sent only when it is available and the line remains idle when there is no information to be transmitted.

In serial asynchronous transmission technique, each character consists of three parts:

1. start bits
2. character bits
3. stop bits

Example:



A transmitted character can be detected by the receiver from the knowledge of the transmission rules:

1. When a character is not being sent, the line is kept in the 1-state.
2. The initiation of a character transmission is detected from the start bit, which is always 0.
3. The character bits always follow the start bit.
4. After the last bit of the character is transmitted, a stop bit is detected when the line returns to the 1-state for at least one bit time.
   - The baud rate is defined as the rate at which serial information is transmitted and is equivalent to the data transfer in bits per second.

Strobe control Employs a single control line to time each transfer. Strobe may be activated by either the source or the destination units.

(a) Source initiated transfer:

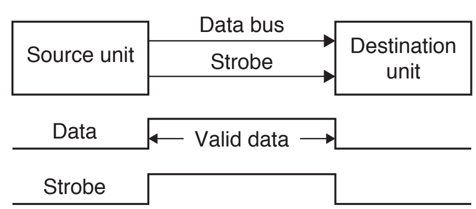


Figure 5 Source initiated strobe for data transfer

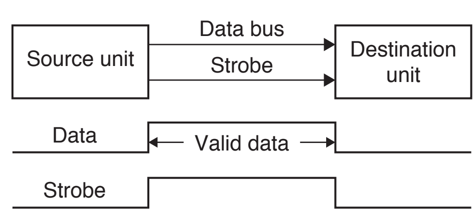
- The data bus carries the binary information from source unit to the destination unit.
- The strobe is a single line that informs the destination unit when a valid data word is available in the bus.

(b) Destination initiated strobe for data transfer:



- The destination unit activates the strobe pulse, informing the source to provide the data. The source unit responds by placing the requested binary information on the data bus.
- The data must be valid and remain in the bus long enough for the destination unit to accept it.
- The falling edge of the strobe pulse can be used again to trigger a destination register. The destination unit then disables the strobe.

Handshaking

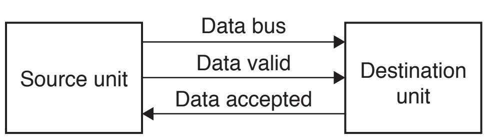
Disadvantage of strobe method: Source unit which initiated the transfer has no way of knowing whether the destination unit has actually received the data item that was placed in the bus.

The handshake method solves this problem by introducing a second control signal that provides a reply to the unit that initiates the transfer.

Principle of two-wire handshaking: One control line is in the same direction as the data flow in the bus from the source to the destination. It is used by the source unit to inform the destination unit whether there are valid data in the bus.

The other control line is in the other direction from the destination to the source. It is used by the destination unit to inform the source whether it can accept data.

The sequence of control during the transfer depends on the unit that initiates the transfer.



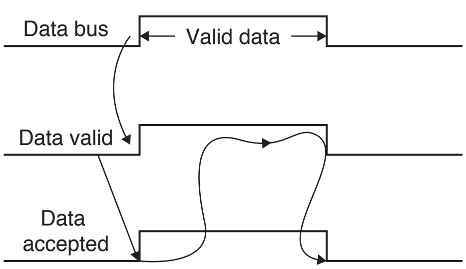


Figure 6 Source initiated transfer using hand shaking

Similarly a destination unit may also initiate the transfer.

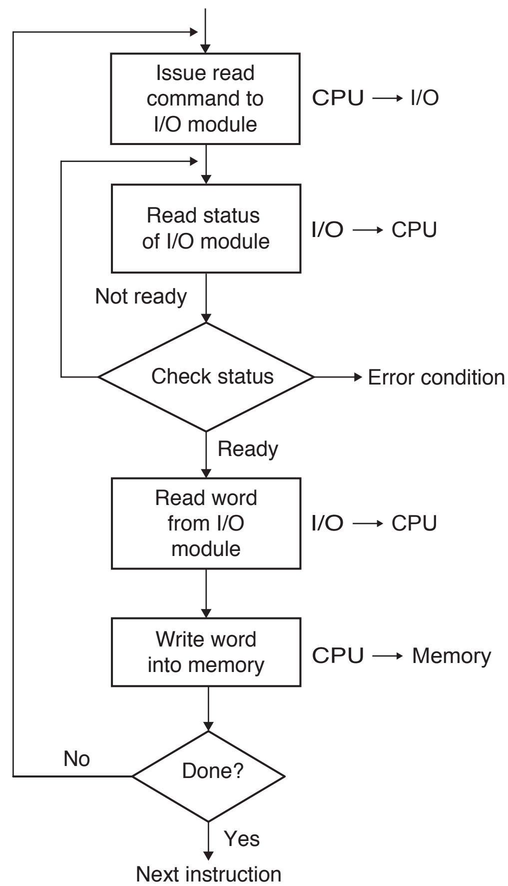
Advantage: Handshaking scheme provides a high degree of flexibility and reliability because the successful completion of a data transfer relies on active participation by both units.

Modes of transfer

There are three different data transfer modes between the central computer (CPU or Memory) and peripherals:

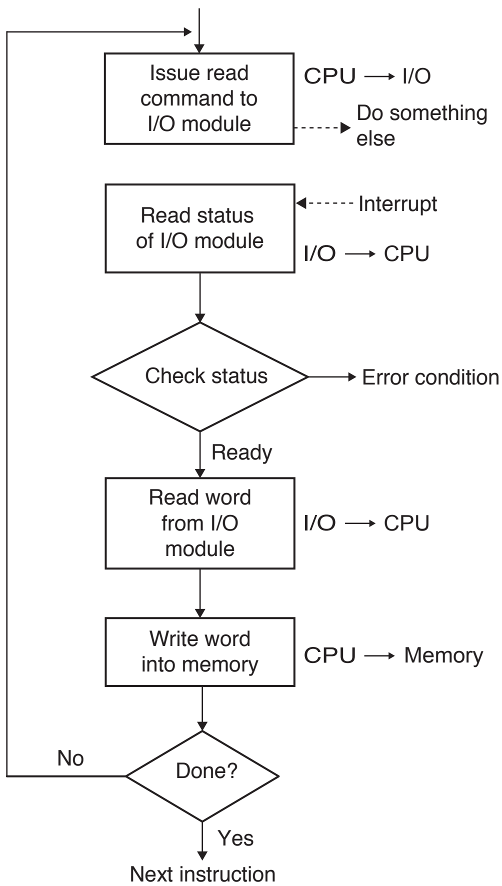
1. Program-controlled I/O
2. Interrupt-initiated I/O
3. Direct memory access

Program-controlled input–output With programmed I/O, the I/O module will perform the requested action and then set the appropriate bits in the I/O status register. The I/O module takes no further action to alert the CPU. In particular it does not interrupt the CPU. Thus, it is the responsibility of the CPU to periodically check the status of the I/O module until it finds that the operation is complete.



Interrupt initiated input–output The problem with programmed I/O is that the CPU has to wait a long time for the I/O module of concern to be ready for either reception or transmission of data. The CPU, while waiting must repeatedly interrogate the status of the I/O module. As a result, the level of the performance of the entire system is severely degraded.

An alternation is for the CPU to issue an I/O command to a module and then go on to do some other useful work. The I/O module will then interrupt the CPU to request service when it is ready to exchange data with the CPU. The CPU then executes the data transfer, as before and then resumes its former processing.



Interrupt Processing: In all computers, there is a mechanism by which the normal processing of the processor is interrupted by other modules like I/O, memory. The interrupts may be of the following class:

1. Program: Generated by some condition that occurs as a result of an instruction execution.

   Examples: Arithmetic overflow, division by zero, etc.
2. Timer: Generated by timer within the processor.
3. I/O: Generated by an I/O controller, to signal normal completion of an operation or to signal a variety of error conditions.
4. Hardware failure: Generated by a failure such as power failure or memory parity error.

Interrupts are provided primarily as a way to improve processing efficiency.

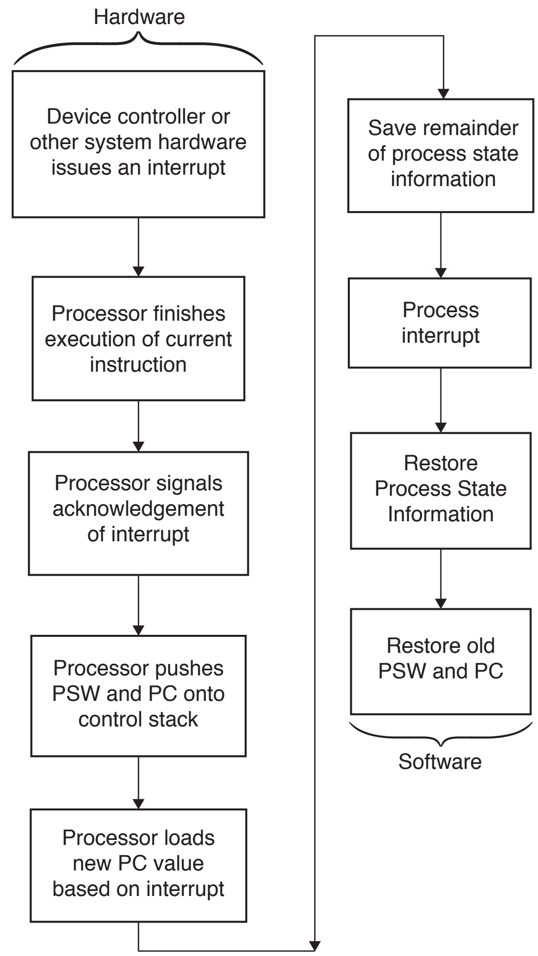


Figure 7 Interrupt Processing Flowchart

Consider the following figures, which show the contents of memory and registers before and after interrupt instruction processing.

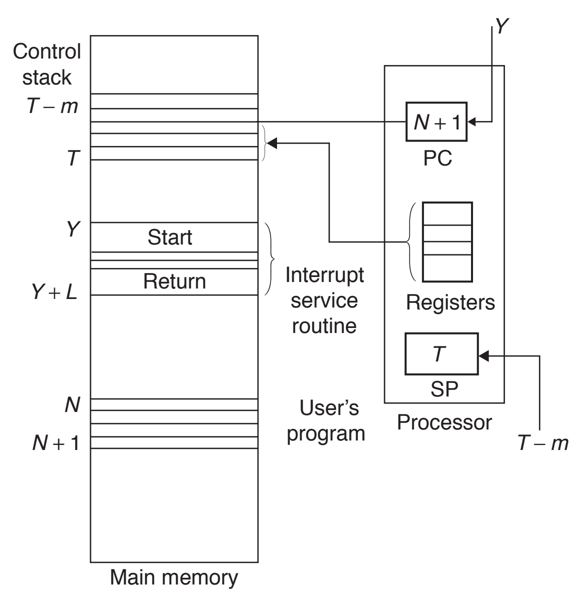

Figure 8 Interrupt occurs after instruction at location *N*

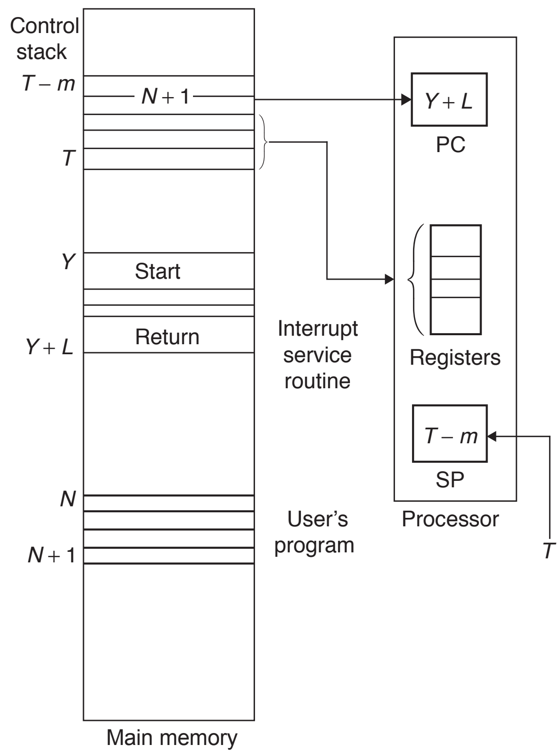

Figure 9 Return from interrupt

Interrupt priority: Priority determines which interrupt is to be served first when two or more requests are made simultaneously. Priority also determines which interrupts are permitted to interrupt the computer while another is being serviced. Higher priority interrupts can make requests while servicing a lower priority interrupt.

Design techniques for interrupts: Two design issues arise in implementing interrupt I/O:

1. Since there will almost invariably be multiple I/O module, how does the CPU determine which device issued the interrupt.
2. If multiple interrupts have occurred, how does the CPU decide which one to process.

Four general categories of techniques are there which are common in use:

(a) Multiple interrupt lines: In this technique, multiple interrupt lines are provided between the CPU and the I/O modules. However, it is impractical to dedicate more than a few bus lines or CPU pins to interrupt lines. Consequently, even if multiple lines are used, it is likely that each line will have multiple I/O modules attached to it. Thus, one of the other three techniques must be used one each line.

(b) Software poll: When the CPU detects an interrupt, it braches to an interrupt-service routine whose job is to poll each I/O module to determine which module generated the interrupt. The poll could be in the form of a separate command line. The CPU receives the command and places the address of a particular I/O module on the address lines. The I/O module responds positively if it set the interrupt. Alternatively, each I/O module could contain an addressable status register. The CPU then read the status register of each I/O module to identify the interrupting module. Once the correct module is identified, the CPU branches to a device service routine specified to that device. It is time consuming.

(c) Daisy chain: Daisy chain in effect provides a hardware poll. For interrupts all I/O modules share a common interrupt request line. The interrupt acknowledge line is daisy chained through the modules. When the CPU is interrupted, it sends out an interrupt acknowledgement. This signal propagates through a series of I/O modules until it gets to a requesting module. The requesting module typically responds by placing a word on the data lines. This word is referred to as a vector and is either the address of the I/O module or some other unique identifier. In either case, the CPU uses the vector as a pointer to the appropriate device-service routine. This avoids the need to execute a general interrupt-service routine first. This technique is referred to as a vectored Interrupt.

(d) Bus arbitration: Bus arbitration is also another technique which makes use of vectored Interrupts. With bus arbitration, an I/O module must first gain control of the bus before it can raise the interrupt request line. Thus only one module can raise the line at a time. When the CPU detects the interrupt, it responds on the interrupt acknowledge line. The requesting module then places its vector on the data lines.

Direct Memory Access (DMA)

Drawbacks of programmed and interrupt-driven I/O:

1. The I/O transfer rate is limited by the speed with which the processor can test and service a device.
2. The processor is tied up in managing I/O transfer; a number of instructions must be executed for each I/O transfer.

Both methods have an adverse impact on both processor activity and I/O transfer rate.

When large volume of data is to be moved, a more efficient technique is required: Direct Memory Access (DMA).

DMA function: DMA involves an additional module on the system bus.

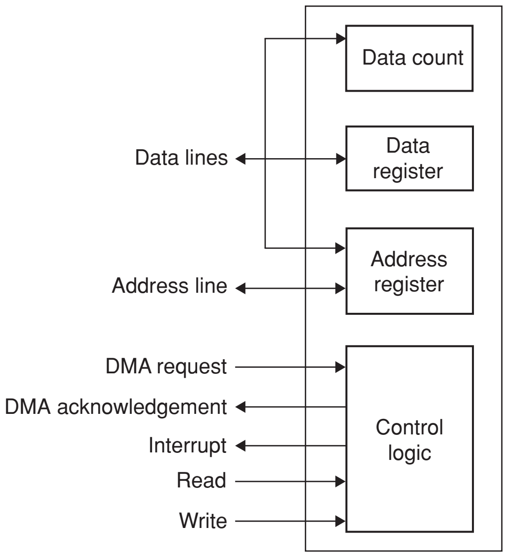

Figure 10 DMA Block Diagram

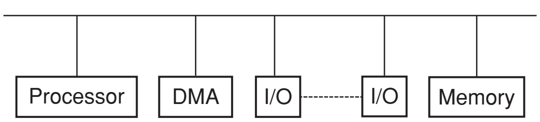
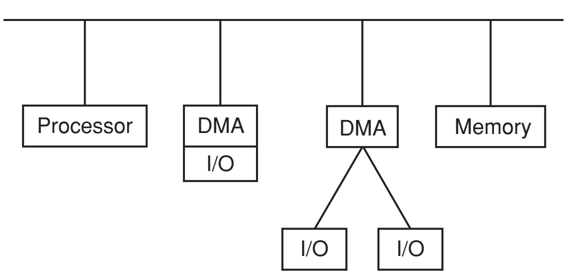
The DMA module is capable of mimicking the processor and indeed, of taking over control of the system from the processor. It needs to do this to transfer data to and from memory over the system bus. For this purpose, the DMA module must use the bus only when the processor does not need it or it must force the processor to suspend operation temporarily. The latter technique is more common and is referred as cycle stealing.

DMA configurations

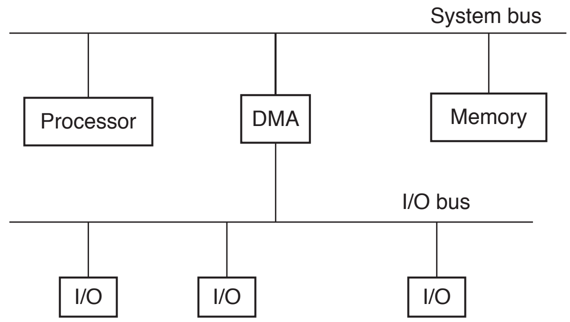
1. **Single bus, detached DMA**
   - Inexpensive, inefficient
   - Each transfer of a word consumes two bus cycles.



2. **Single bus, integrated DMA I/O** There is a path between the DMA module and one or more I/O modules that does not include system bus.



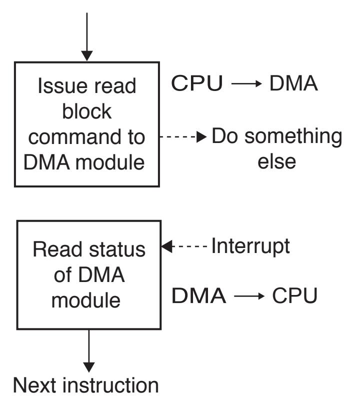
3. **I/O bus**
   - Reduces the number of I/O interfaces in the DMA module to one.
   - Easily expandable configuration.



With DMA, when the CPU wishes to read or write a block of data, it issues a command to the DMA module, by sending the following information to the DMA module.

1. Whether a read or write is requested.
2. The address of the I/O device involved.
3. The starting location in memory to read from or write to.
4. The number of words to be read or written.

The CPU then continues with other work. It has delegates this I/O operation to the DMA module, and that module will take care of it. The DMA module transfers the entire block of data, one word at a time, directly to or from memory, without going through the CPU. When the transfer is complete, the DMA module sends an interrupt signal to the CPU. Thus, the CPU is involved only at the beginning and end of the transfer.



DMA transfer can either happen as:

1. **Burst transfer**
   - A block sequence consisting of a number of memory words is transferred in continuous burst.
   - DMA controller is master of memory Buses.
   - This mode of transfer is needed for fast devices such as Magnetic Disks, where transmission cannot be stopped or slowed down.
2. **Cycle stealing**
   - CPU is usually much faster than I/O (DMA), thus CPU uses the most of the memory cycles.
   - DMA controller steals the memory cycles from CPU.
   - For those stolen cycles, CPU remains idle.

- For those slow CPU, DMA Controller may steal most of the memory.
- Cycle stealing, which may cause CPU remain idle long time.

Input–Output Processor (IOP)

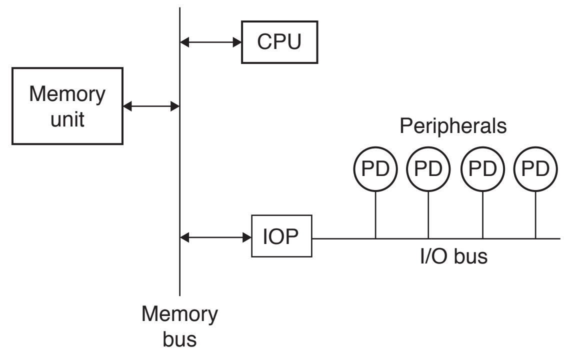
An IOP is a processor, having a direct memory access capability, used to communicate with I/O devices.

In this configuration, the computer system can be divided into a memory unit and a number of processors comprised of the CPU and one or more IOPs.

Each IOP takes care of input and output tasks, relieving the CPU from the house keeping chores involved in I/O transfers.

- IOP is similar to a CPU except that it is designed to handle the details of I/O processing.
- Unlike DMA, the IOP can fetch and execute its own instructions.

The following figure shows a computer with two processors:



Exercises

Practice Problems I

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider a DRAM that must be given a refresh cycle 64 times per ms. Each refresh operation requires 150 ns, a memory cycle requires 250 ns. What is the approximate percentage of the memory's total operating time must be given to refreshes?
(A) 1% (B) 2%
(C) 9% (D) 60%

2. A DMA controller transfers 16-bit words to memory using cycle stealing. The words are assembled from a device that transmits characters at a rate of 2400 characters per second. The CPU is fetching and executing instructions at an average rate of 1 million instructions per second. By how much time will the CPU be slowed down because of the DMA transfer?
(A) 0.6% (B) 0.1%
(C) 0.12% (D) 0.24%

3. A system is based on a 16-bit microprocessor and has two I/O devices. The I/O controllers for this system use separate control and status registers. Both devices handle data on a one-byte-at-a time basis. The first device has two status lines and three control lines. The second device has three status lines and four control lines. How many 16-bit I/O control module registers do we need for status reading and control of each device?
(A) 1, 2 (B) 2, 1
(C) 2, 2 (D) 1, 1

4. In a programmed I/O technique, the processor is stuck in a wait loop doing status checking of an I/O device. To increase efficiency, the I/O software could be written so that the processor periodically checks the status of the device. If the device is not ready, the processor can jump to other tasks. After some timed interval, the processor comes back to check status again. Let us assume that above scheme is used for outputting data one character at a time to a printer that operates at 10 characters per second (CPS). Which of the following statement is true if its status is scanned every 200 ms?
(A) The printing speed is increased by 5 CPS
(B) The printing rate is slowed to 5 CPS
(C) The printing rate is at 10 CPS only
(D) The printing rate is at 20 CPS

5. Consider a system employing interrupt-driven I/O for a particular device that transfers data at an average of 8 KB/s on a continuous basis. The interrupt processing takes about 100 μs and the I/O device interrupts processor for every byte. Let assume that the device has two 16-byte buffers and interrupts the processor when one of the buffer is full. While executing the ISR, the processor takes about 8 μs for the transfer of each byte. Then what is the fraction of processor time is consumed by this I/O device?
(A) 8% (B) 11%
(C) 50% (D) 65%

6. A 32-bit computer has two selector channels one multiplexor channel. Each selector channel supports two magnetic disks and three magnetic tape units. The multiplexor channel has two line printers, two card readers and 10 VDT terminals connected to it. Assume the following transfer rates:

Disk drive: 1000 KB/sec
Magnetic tape drive: 300 KB/sec
Line printer: 6.2 KB/sec
Card reader: 2.4 KB/sec
VDT: 1 KB/sec

What is the maximum aggregate I/O transfer rate of this system?
(A) 1625.6 KB/s (B) 1327.2 KB/s
(C) 2027.2 KN/s (D) 2327.2 KB/s

7. Consider a disk drive with 16 surfaces, 512 tracks per surface and 512 sectors per track, 1 kilo bytes per sector and a Rotation speed of 3000 RPM. The disk is operated in cycle stealing mode where by whenever one 4 byte word is ready it is sent to memory; similarly, for writing, the disk interface read a 4 byte word from the memory in each DMA cycle. The memory cycle time is 40 nsec. Find the maximum percentage of time that the CPU gets blocked during DMA operation?
(A) 2.62% (B) 26.21%
(C) 0.26% (D) 0.52%

8. How many RAM chips of size (256 K × 1-bit) are needed to build a 1 M Byte memory?
(A) 16 (B) 8
(C) 32 (D) 24

9. Four memory chips of 16 × 4 size have their address bases connected together. The whole system will have a size of
(A) 16 × 8 (B) 64 × 64
(C) 16 × 16 (D) 256 × 1

10. In which of following I/O techniques, there will be no interrupt?
(A) Programmed I/O (B) Interrupt-driven I/O
(C) DMA (D) Both (B) and (C)

11. The capacity of a memory unit is defined by the number of words multiplied by the number of bits/word. How many separate address and data lines are needed for a memory 16K × 16?
(A) 10 address, 4 data lines
(B) 14, 4
(C) 14, 16
(D) 14, 14

12. The main problem of strobe asynchronous data transfer is
(A) it employs a single control line
(B) it is controlled by clock pulses in the CPU.
(C) the falling edge again used to trigger
(D) no way of knowing whether the destination has received the data item.

13. Which of the following DMA transfer modes and interrupt handling mechanisms will enable the highest I/O bandwidth?
(A) Block transfer and polling interrupt
(B) Cycle stealing and polling interrupt
(C) Block transfer and vectored interrupt
(D) Transparent DMA and vectored interrupt

14. Which of the following enables peripherals to pass a signal down the bus to the next device on the bus during polling of the device?
(A) Interrupt vectoring (B) Cycle stealing
(C) DMA (D) Daisy chain

15. What will be the response of the CPU, on receiving an interrupt from an input/output device?
(A) It hands over the control of address bus and data bus to the interrupting device.
(B) It branches off to the interrupt service routine after completion of the current instruction.
(C) It halts for a predetermined time.
(D) It branches off to the interrupt service routine immediately.

16. What is the bandwidth of memory system that has a latency of 50ns, a pre charge time of 10ns and transfers 2 bytes of data per access?
(A) 60 B/sec (B) 1.67 B/sec
(C) 1.67×10^7 B/sec (D) 3.33×10^7 B/sec

17. A hard disk is connected to a 50MHz processor through a DMA controller. Assume that the initial set-up of a DMA transfer takes 2000 clock cycles for the processor and also assume that the handling of the interrupt at DMA completion requires 1000 clock cycles for the processor. The hard disk has a transfer rate of 4000 K bytes/sec and average block size transferred is 8 K bytes. What fraction of the processor time is consumed by the disk, if the disk is actively transferring 100% of the time?
(A) 1% (B) 1.5%
(C) 2% (D) 3%

18. A device with transfer rate of 20KB/sec is connected to a CPU. Data is transferred byte wise. Let the interrupt overhead is 6 micro seconds. The byte transfer time between the device interface register and CPU or memory is negligible. What is minimum performance gain of operating the device under interrupt mode over operating it under program-controlled mode?
(A) 6 (B) 8
(C) 10 (D) 12

19. A DMA module is transferring characters to main memory from an external device at 76800 bits per second. The processor can fetch instructions at a rate of 2 million instructions per second. How much will the processor be slowed down due to DMA activity? (Express this as a percent of the time from when there is a conflict between DMA and the CPU)
(A) 0.24% (B) 0.48%
(C) 0.96% (D) 0.50%

20. Let us suppose that we want to read 2048 bytes in programmed I/O mode of CPU. The bus width is 32-bits. Each time an interrupt occurs from Hard disk drive and it taken 4 μsec to service it. How much CPU time is required to read 2048 bytes?
(A) 512 msec (B) 768 msec
(C) 1024 msec (D) 2048 msec

Practice Problems 2

Directions for questions 1 to 21: Select the correct alternative from the given choices.

1. Memory which is ultraviolet erasable is
(A) RAM (B) EPROM
(C) PROM (D) EEPROM

2. Memory which is electrically erasable is
(A) EPROM (B) EEPROM
(C) ROM (D) PROM

3. The minimum time delay that is required between the initiation of two successive memory operations is called
(A) Memory access time (B) Transmission time
(C) Seek Time (D) Memory cycle

4. The memory that is programmed at the time of manufacture is
(A) RAM (B) PROM
(C) ROM (D) EEPROM

5. The disadvantage of dynamic RAM over static RAM is
(A) High power consumption
(B) Higher bit density
(C) Need to refresh the capacitor charge every once in two milliseconds.
(D) Variable speed

6. If an error is detected, a part of the memory can be erased in
(A) PROM (B) EPROM
(C) EAROM (D) EROM

7. What are sequences of events in source initiated hand shaking transfer?
(A) Source enable data valid, destination enable data accepted, source disable data valid, destination disable data accepted
(B) Source disable data valid, destination enable data accepted, source disable data valid, destination enable data accepted
(C) Source disable data valid, destination Disable data valid, source enable data valid, destination enable data accepted.
(D) Source disable data valid, destination enable data valid, source enable data valid, destination disable data accepted.

8. Processor needs software interrupt to
(A) return from subroutine
(B) implement co-routines
(C) test the interrupt system of the processor
(D) obtain system services which need execution of privileged instructions

9. A microcomputer has primary memory of 512 KB. what is the exact number of bytes contained in this memory?
(A) 512×1000 (B) 512×100
(C) 512×1024 (D) 512×1028

10. The number of address lines required in a microprocessor which has to access 1 K bytes of memory is
(A) 6 (B) 4
(C) 10 (D) 8

11. Software interrupt is
(A) used to stimulate an external device
(B) generated by an external device
(C) Both (A) and (B)
(D) None of these

12. The bus that is used to transfer data from main memory to peripheral devices and vice-versa is
(A) Control bus (B) input bus
(C) output bus (D) DMA bus

13. The bus which is connected between the CPU and the main memory that permits transfer of information between the CPU and main memory is called
(A) memory bus (B) address bus
(C) control bus (D) DMA bus

14. An interrupt in which the external device supplies the interrupt requests as well as its address is called
(A) maskable interrupt
(B) vectored interrupt
(C) designated interrupt
(D) non-maskable interrupt

15. A temporarily ignored interrupt is called
(A) designated interrupt
(B) maskable interrupt
(C) non-maskable interrupt
(D) low priority interrupt

16. Which of the following device is used to connect a peripheral to a bus?
(A) control register
(B) interface
(C) communication protocol
(D) None of these

17. Which of the following is true for the daisy scheme of connecting input/output devices?
(A) It gives non-uniform priority to various devices.
(B) It gives uniform priority to all devices.
(C) It is only useful for connecting slow devices to a processor device.
(D) It requires a separate interrupt pin on the processor for each device.

18. In direct memory access data are directly transferred
(A) from CPU to input/output device and memory
(B) from an input/output device to memory only.
(C) from memory to an input/output device only.
(D) from an input/output device to the memory or vice versa

19. Which one of the following is true for a CPU having a single interrupt request line and a single interrupt grant line?
(A) Vectored interrupt multiple interrupting devices are always possible.
(B) Vectored interrupts are not possible but multiple interrupting devices are possible
(C) Vectored interrupts and multiple interrupting devices are sometimes possible
(D) Vectored interrupt is possible but multiple interrupting devices are not possible

20. In which of the following I/O, there is a single address space for memory locations and I/O devices
(A) Isolated I/O
(B) Memory mapped I/O
(C) DMA
(D) Both (A) and (B)

21. ____ signal used to interrupt processor and to execute service routine that takes an error recovery action.
(A) Strobe (B) Handshaking
(C) Polling (D) Time out

Previous Years' Questions

1. A device with data transfer rate 10 KB/sec is connected to a CPU. Data is transferred byte-wise. Let the interrupt overhead be 4 μsec. The byte transfer time between the device interface register and CPU or memory is negligible. What is the minimum performance gain of operating the device under interrupt mode over operating it under program-controlled mode? **[2005]**
(A) 15 (B) 25
(C) 35 (D) 45

2. A computer handles several interrupt sources of which the following are relevant for this question.
- Interrupt from CPU temperature sensor (raises interrupt if CPU temperature is too high)
- Interrupt from Mouse (raises interrupt if the mouse is moved or a button is pressed)
- Interrupt from Keyboard (raises interrupt when a key is pressed or released)
- Interrupt from Hard Disk (raises interrupt when a disk read is completed)

Which one of these will be handled at the HIGHEST priority? **[2011]**
(A) Interrupt from Hard Disk
(B) Interrupt from Mouse
(C) Interrupt from Keyboard
(D) Interrupt from CPU temperature sensor

The following information pertains to 3 and 4: Consider the following program segment for a hypothetical CPU having three user registers R_1, R_2 and R_3.

Instruction	Operation	Instruction Size (in words)
MOV R_1, 5000;	$R_1 \leftarrow$ Memory [5000]	2
MOV R_2 (R1);	$R_2 \leftarrow$ Memory [(R_1)]	1
ADD R_2, R3;	$R_2 \leftarrow R_2 + R_3$	1
MOV 6000, R_2;	Memory [6000] $\leftarrow R_2$	2
HALT;	Machine halts	1

3. Consider that the memory is byte addressable with size 32 bits, and the program has been loaded starting from memory location 1000 (decimal). If an interrupt occurs while the CPU has been halted after executing the HALT instruction, the return address (in decimal) saved in the stack will be **[2004]**
(A) 1007 (B) 1020
(C) 1024 (D) 1028

4. Let the clock cycles required for various operations be as follows:
Register to/from memory transfer: 3 clock cycles
ADD with both operands in register: 1 clock cycle
Instruction fetch and decode: 2 clock cycles per word
The total number of clock cycles required to execute the program is **[2004]**
(A) 29 (B) 24
(C) 23 (D) 20

5. A CPU generally handles an interrupt by executing an interrupt service routine **[2009]**
(A) As soon as an interrupt is raised.
(B) By checking the interrupt register at the end of fetch cycle.
(C) By checking the interrupt register after finishing the execution of the current instruction.
(D) By checking the interrupt register at fixed time intervals.

6. A hard disk with a transfer rate of 10 Mbytes/second is constantly transferring data to memory using DMA. The processor runs at 6000 MHz, and takes 300 and 900 clock cycles to initiate and complete DMA transfer respectively. If the size of the transfer is 20 Kbytes, what is the percentage of processor time consumed for the transfer operation?
(A) 5.0% (B) 1.0%
(C) 0.5% (D) 0.1%

7. On a non-pipelined sequential processor, a program segment, which is a part of the interrupt service routine, is given to transfer 500 bytes from an I/O device to memory.

Initialize the address register.

Initialize the count to 500

LOOP: Load a byte from device

Store in memory at address given by address register.

Increment the address register

Decrement the count

If count! = 0 go to LOOP

Assume that each statement in this program is equivalent to a machine instruction which takes one clock cycle to execute if it is a non-load/store instruction. The load-store instructions take two clock cycles to execute.

The designer of the system also has an alternate approach of using the DMA controller to implement the same transfer. The DMA controller requires 20 clock cycles for initialization and other overheads. Each DMA transfer cycle takes two clock cycles to transfer one byte of data from the device to the memory.

What is the approximate speedup when the DMA controller based design is used in place of the interrupt driven program based input-output? **[2011]**

(A) 3.4 (B) 4.4
(C) 5.1 (D) 6.7

8. Which of the following statements about synchronous and asynchronous I/O is NOT true? **[2008]**
(A) An ISR is invoked on completion of I/O in synchronous I/O but not in asynchronous I/O
(B) In both synchronous and asynchronous I/O, an ISR (Interrupt Service Routine) is invoked after completion of the I/O
(C) A process making a synchronous I/O call waits until I/O is complete, but a process making an asynchronous I/O call does not wait for completion of the I/O
(D) In the case of synchronous I/O, the process waiting for the completion of I/O is woken up by the ISR that is invoked after the completion of I/O

9. A main memory unit with a capacity of 4 megabytes is built using 1M × 1-bit DRAM chips. Each DRAM chip has 1K rows of cells with 1K cells in each row. The time taken for a single refresh operation is 100 nanoseconds. The time required to perform one refresh operation on all the cells in the memory unit is **[2010]**
(A) 100 nanoseconds
(B) 100 * 2^{10} nanoseconds
(C) 100 * 2^{20} nanoseconds
(D) 3200 * 2^{20} nanoseconds

10. A processor can support a maximum memory of 4GB, where the memory is word - addressable (a word consists of two bytes). The size of the address bus of the processor is atleast ___ bits. **[2016]**

11. The size of the data count register of a DMA controller is 16 bits. The processor needs to transfer a file of 29,154 kilobytes from disk to main memory. The memory is byte addressable. The minimum number of times the DMA controller needs to get the control of the system bus from the processor to transfer the file from the disk to main memory is _____. **[2016]**

12. The following are some events that occur after a device controller issues an interrupt while process *L* is under execution.
(P) The processor pushes the process status of *L* onto the control stack.
(Q) The processor finishes the execution of the current instruction.
(R) The processor executes the interrupt service routine.
(S) The processor pops the process status of *L* from the control stack.
(T) The processor loads the new PC value based on the interrupt.

Which one of the following is the correct order in which the events above occur? **[2018]**
(A) QPTRS (B) PTRSQ
(C) TRPQS (D) QTPRS

13. A 32-bit wide main memory unit with a capacity of 1 GB is built using 256 M × 4-bit DRAM chips. The number of rows of memory cells in the DRAM chip is 2^{14}. The time taken to perform one refresh operation is 50 nanoseconds. The refresh period is 2 milliseconds. The percentage (rounded to the closest integer) of the time available for performing the memory read write operations in the main memory unit is ______. **[2018]**

Chapter 4

Instruction Pipelining

LEARNING OBJECTIVES

- *Flynn's classification*
- *Pipelining*
- *Six-stages of pipelining*
- *Pipeline performance*
- *Pipeline hazards*
- *Structural hazards*
- *Data hazards*
- *Control hazards*
- *Conditional branch*
- *Dealing with branches*

Flynn's Classification

In parallel processing, the system is able to perform concurrent data processing to achieve faster execution time. A classification introduced by M.J. Flynn considers the organization of a computer system by the number of instructions and data items that are manipulated simultaneously. According to this classification, there are four major groups of computers:

1. **Single instruction stream, single data stream (SISD):**
   - Single computer containing a control unit, a processor unit and a memory unit
   - Instructions executed sequentially; parallel processing may be achieved by multiple functional units or by pipeline processing.
2. **Single instruction stream, Multiple data stream (SIMD):**
   - Include many processing units under the supervision of a common control unit.
   - All processors receive the same instruction from the control unit but operate on different items of data.
3. **Multiple instruction stream, Single data stream (MISD):**
   - No practical system has been constructed.
4. **Multiple instruction stream, Multiple data stream (MIMD):**
   - Capable of processing several programs at the same time.

One type of parallel processing that does not fit Flynn's classification is pipelining.

Pipelining

Pipelining is a technique of decomposing a sequential process into sub operations, with each subprocess being executed in special dedicated segment that operates with all other segments.

In pipelining, new inputs are accepted at one end before previously accepted inputs appear as outputs at the other end.

Two-stage Pipeline

As a simple approach, consider subdividing instruction processing into two stages:

1. Fetch instruction
2. Execute instruction
   - There are times during the execution of an instruction when main memory is not being accessed. This time can be used to fetch the next instruction in parallel with the execution of the current one. This is called instruction prefetch or fetch overlap.
   - This process will speed up instruction execution. If the fetch and execute stages were of equal duration, the instruction cycle time would be halved.
   - But there are some problems in this technique:
     (i) The execution time is generally longer than the fetch time.
     (ii) A conditional branch instruction makes the address of the next instruction to be fetched unknown.
   - These two factors reduce the potential effectiveness of the two-stage pipeline, but some speed up occurs. To gain further speed up, the pipeline must have more stage(s).

Six-stage Pipeline

Let the six stages be

F: Fetch Instruction
D: Decode Instruction
C: Calculate Operand Address
O: Operand Fetch

E: Execute instruction
W: Write operand

Then the time line diagram for seven instructions is shown below:

Clock cycle	1	2	3	4	5	6	7	8	9	10	11	12
Instruction i	F	D	C	O	E	W						
$i+1$		F	D	C	O	E	W					
$i+2$			F	D	C	O	E	W				
$i+3$				F	D	C	O	E	W			
$i+4$					F	D	C	O	E	W		
$i+5$						F	D	C	O	E	W	
$i+6$							F	D	C	O	E	W

Execution Time for the seven instructions with pipelining $=\left(\frac{t_{ex}}{6}\right)\times 12 = 2 * t_{ex}$. Where t_{ex} in the execution time required for each instruction.

- A deeper pipeline means that there are more stages in the pipeline. This generally means that the processor's frequency can be increased as the cycle time is lowered. This happen because there are fewer components in each stage of the pipeline, so the propagation delay is decreased for the overall stage.
- An instruction pipeline is said to be fully pipelined if it can accept a new instruction in every clock cycle.
- A pipeline that is not fully pipelined has wait cycle that delays the progress of the pipeline.

Advantages of pipelining:

- The cycle time of the processor is reduced, thus increasing instruction issue rate in most cases.
- Some combinational circuits such as adders or multipliers can be made faster by adding more circuitry. If pipelining is used instead it can save circuitry versus a more complex combinational circuit.

Limitations of pipelining:

1. If the stages are not of equal duration, there will be some waiting involved at various stages.
2. Conditional branch instruction may invalidate several instruction fetches.
3. The contents of one stage may depend on the contents of other stages of previous instructions, which is still in pipeline.

Pipeline Performance

The cycle time τ of an instruction pipeline is the time needed to advance a set of instructions one stage through the pipeline.

$$\text{Cycle time} = \max[\tau_i] + d = \tau_m + d,\ 1 \le i \le K$$

where τ_i = Time delay of the circuitry in the i^{th} stage of the pipeline.

τ_m = maximum stage delay.
K = number of stages in instruction pipeline
d = time delay of a latch, needed to advance signals and data from one stage to the next.

Suppose that n instructions are processed without any branches. Let $T_{k,n}$ be the total time required for a pipeline with K stages to execute n instructions. Then

$T_{k,n} = [K+(n-1)]\tau$

Example 1: Let $n = 7$, $K = 6$, $\tau = 1$. Then $T_{k,n} = [6 + (7 - 1)] \times 1 = 12$ cycles.

Now consider a processor with equivalent functions but no pipeline and assume that the instruction cycle time is $k\tau$. The speed up factor for the instruction pipeline compared to execution without the pipeline is defined as

$$S_k = \frac{T_{1,n}}{T_{k,n}} = \frac{nk\tau}{[(k+(n-1)]\tau} = \frac{nk}{k+(n-1)}$$

Note: Larger the number of stages, greater the potential for speed up. But practically, the potential gains of additional pipeline stages are countered by increase in cost, delays between stages, and the fact that braches will be encountered requiring the flushing of the pipeline.

Arithmetic pipeline:

- Pipeline arithmetic units are usually found in very high-speed computers.
- These are used to implement floating point operations, multiplication of fixed point numbers and similar computations encountered in scientific problems.

Pipeline Hazards

- Pipeline hazards are situations that prevent the next instruction in the instruction stream from executing during its designated clock cycle. The instruction is said to be stalled. When an instruction is stalled, all instructions later in the pipeline than the stalled instructions are also stalled. Instructions earlier than the stalled one can continue. No new instructions are fetched during the stall.

Note: Keeping a pipeline at its maximal rate is prevented by pipeline hazard.

Different types of Hazards:

1. Structural Hazards
2. Data Hazards
3. Control Hazards

Structural Hazards

Structural hazards occur when a certain resource is requested by more than one instruction at the same time.

Example 2: Instruction MVI B, X fetches in the O stage operand X from memory. The memory does not accept another access during that cycle.

Clock cycle	1	2	3	4	5	6	7	8	9	10	11
MVI *B*, *X*	F	D	C	O	E	W					
Instruction *i* + 1		F	D	C	O	E	W				
i + 2			F	D	C	O	E	W			
i + 3				stall	F	D	C	O	E	W	
i + 4						F	D	C	O	E	W

Penalty: 1 cycle

Certain resources are duplicated in order to avoid structural hazards (ALU, floating-point unit) can be pipelined themselves in order to support several instructions at a time. A classical way to avoid hazards at memory access is by providing separate data and instruction caches.

Note: Structural hazards are due to resource conflict.

Data Hazards

In a pipeline execution of two instructions I_1 and I_2 a certain stage of the pipeline I_2 needs the result produced by I_1, but this result has not yet been generated, then we have a data hazard.

Example 3: I_1: ADD R_3, R_2 $\quad R_3 \leftarrow R_3 + R_2$

I_2: MUL R_1, R_3 $\quad R_1 \leftarrow R_1 * R_3$

Clock cycle	1	2	3	4	5	6	7	8	9	10	11	12
ADD R_3, R_2	F	D	C	O	E	W						
MUL R_1, R_3		F	D	C	stall	stall	O	E	W			
Instruction *i* + 2			F	D			C	O	E	W		

Penalty: 2 cycles Before executing the O stage (operand fetch stage), the MUL instruction is stalled until the ADD instruction has written the result into R_3.

Data dependencies

Data dependency exists between two instructions if the data data used by an instruction depends on the data created by other instructions.

Two type of dependencies exist between instructions:

1. True data dependency
2. Name dependencies
   (i) Anti-dependency
   (ii) Output dependency

True data dependency

- This is also called as Read-After-Write Hazard (RAW).
- This type of dependency occurs when the value produced by an instruction is required by a subsequent instruction.
- This is also known as a flow dependency because dependency is due to flow of data in a program.

Example: ADD R_3, R_2, R_1; $R_3 \leftarrow R_2 + R_1$

SUB R_4, R_3, 1; $R_4 \leftarrow R_3 - 1$

- Here R_3 is read before it is written by 'ADD' instruction.
- In RAW hazard $(i + 1)^{st}$ instruction tries to read a source before it is written by 'i^{th}' instruction. So $(i + 1)^{st}$ instruction incorrectly gets the old value.
- This kind of hazard can be reduced by using forwarding (or Bypassing).

Name dependencies

1. **Anti-dependency:**
   - This is also called as Write-After-Read hazard
   - This kind of dependency occurs when an instruction writes to a location which has been read by a previous instruction.
   - Here $(i + 1)^{st}$ instruction tries to write an operand before it is read by i^{th} instruction. So i^{th} instruction incorrectly gets the new value.

Example: I_1: ADD R_3, R_2, R_1 ;$R_3 \leftarrow R_2 + R_1$

I_2: SUB R_2, R_5, 1; $R_2 \leftarrow R_5 - 1$

I_2 must not produce its result in R_2 before I_1 read R_2, otherwise I_1 would use the value produced by I_2 rather than the previous value of R_2.

2. **Output dependency:**
   - This is also called as Write-After-Write (WAW) hazard.
   - This dependency occurs when a location is written by two instructions.
   - i.e., $(i + 1)$th instruction tries to write an operand before it is written by i^{th} instruction.

   The writes end up being performed in the wrong order.

Example: I_1: ADD R_3, R_2, R_1; $R_3 \leftarrow R_2 + R_1$

I_2: SUB R_2, R_3, 1; $R_2 \leftarrow R_3 - 1$

I_3: R_3, R_2, R_5; $R_3 \leftarrow R_2 + R_5$

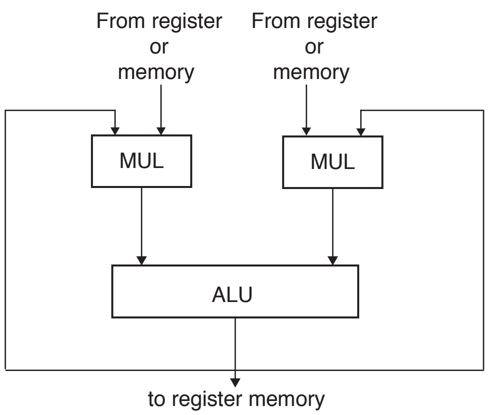
There is a possibility of WAW hazard between I_1 and I_3.

Handling data dependency There are ways to handle date dependency.

1. Hardware interlocks
2. Operand forwarding
3. Delayed load

1. **Hardware interlocks:**
   - To avoid data dependency, insert hardware interlock.
   - An interlock is a circuit that detects instructions whose source operands are destinations of instructions farther up in the pipeline.
2. **Operand forwarding:**
   - Uses special hardware to detect a conflict and then avoid it by routing the data through special paths between pipeline segments.

- Some of the penalty produced by data hazards can be avoided using a technique called forwarding (Bypassing).
- The ALU result is always fed back to the ALU input. If the hardware detects that the value needed for the current operation is the one produced by the previous operation (but which has not yet been written back). It selects the forwarded result as the ALU input, instead of the value read from register or memory.



Clock cycle	1	2	3	4	5	6	7	8
ADD R_3, R_2	F	D	C	O	E	W		
MUL R_1, R_3		F	D	C	stall	O	E	W

Penalty: 1 cycle After the E stage of the MUL instruction the result is available by forwarding. Therefore the penalty is reduced to one cycle.

Delayed Load: Here the compiler of a computer will detect the data conflicts and reorder the instructions as necessary to delay the loading of the conflicting data by inserting no-operation instruction.

Control Hazards

Control hazards are produced by Branch Instructions.

Unconditional branch

- Jump loop
- Loop

Clock cycle	1	2	3	4	5	6	7	8	9	10	11
Loop	F	D	C	O	E	W					
Loop		stall	stall	stall	F	D	C	O	E	W	
Loop + 1						F	D	C	O	E	W

Penalty: 3 cycles

- The instruction following the branch is fetched before the D stage is finished in 2nd clock. It is not known that a branch is executed. Later the fetched instruction is discarded.
- After the O stage of the branch instruction the address of the target is known and it can be fetched.

Conditional branch

Example: ADD B; $A \leftarrow A + B$
JZ Loop

Loop: If condition satisfies and branch is taken:

Clock cycle	1	2	3	4	5	6	7	8	9	10	11	12
ADD *B*	F	D	C	O	E	W						
JZ Loop		F	D	C	O	E	W					
Loop			stall	stall	stall	F	D	C	O	E	W	

Penalty:3 cycles

At this moment both the condition (set by ADD) and the target address are known.

If condition not satisfied and branch not taken:

Clock cycle	1	2	3	4	5	6	7	8	9	10	11	12
ADD *B*	F	D	C	O	E	W						
JZ Loop		F	D	C	O	E	W					
Instruction $i + 1$			F	stall	stall	D	C	O	E	W		

Penalty:2 cycles

At this moment the condition is known and instruction i + 1 can go on.

- With conditional branch, we have a penalty even if the branch has not been taken. This is because we have to wait until the branch condition is available.

Dealing with branches

One of the major problems in designing an instruction pipeline is the occurrence of branch instructions. A variety of approaches have been taken for dealing with braches

1. Multiple streams
2. Prefetch branch target
3. Branch target buffer
4. Loop buffer
5. Branch prediction
6. Delayed branch

Multiple streams A branch instruction may cause to choose one of two instructions to fetch next, then allow the pipeline to fetch both instructions, making use of streams.

There are two problems with this approach:

1. With multiple pipelines there are contention delays for access to the registers and to memory.
2. Additional branch instructions may enter the pipeline before the original branch decision is resolved.

Prefetch branch target When a conditional branch is recognized, the target of the branches is prefetched, in addition to the instruction following the branch. This target is then saved until the branch instruction is executed.

Branch targets buffer (BTB) BTB is an associative memory included in the fetch segment of the pipeline. Each entry in the BTB consists of the address of a previously executed branch instruction and target instructions for that branch.

It also stores the next few instructions after the branch target instruction.

When the pipeline decodes a branch instruction, it searches the associative memory BTB for the address of the instruction. If it is in BTB, the instruction is available directly and prefetch continues from the new path. If the instruction is not in BTB, the pipeline shifts to a new instruction stream and stores the target instruction in the BTB.

Advantage: Branch instructions that occurred previously are readily available in the pipeline without interruption.

Loop Buffer A loop buffer is a small, very high speed memory maintained by the instruction fetch stage of the pipeline and containing the n most recently fetched instructions in sequence. If a branch is to be taken, the hardware first checks whether the branch target is within the buffer. If so, the next instruction is fetched from the buffer. The Advantages of loop buffer are

1. Loop buffer will contain some instructions sequentially ahead of the current instruction fetch address. Thus instructions fetched in sequence will be available without the usual memory access time.
2. If the branch occurs to a target just a few locations ahead of the address of the branch instruction, the target will already be in the buffer.
3. This strategy is well suited in dealing with loops.

Branch prediction Various techniques can be used to predict whether a branch will be taken or not. The common techniques are

Static:
1. Predict never taken Static
2. Predict always taken
3. Predict by opcode

Dynamic:
4. Taken/not taken switch
5. Brach history table

- The first two approaches are static, i.e., no dependency on execution history. Here always assume that the branch will not be taken and continue to fetch instructions in sequence, or always assume that the branch will be taken and always fetch from the branch target.
- The third approach is also static. Takes the decision based on the opcode of the branch instruction in a program.
- Dynamic branch strategies attempt to improve the accuracy of prediction by recording the history of conditional branch instructions in a program.

(a) Taken/not taken switch:

- Use two bits to record the result of the last two instances of the execution of the associated instruction or record a state in some other fashion.

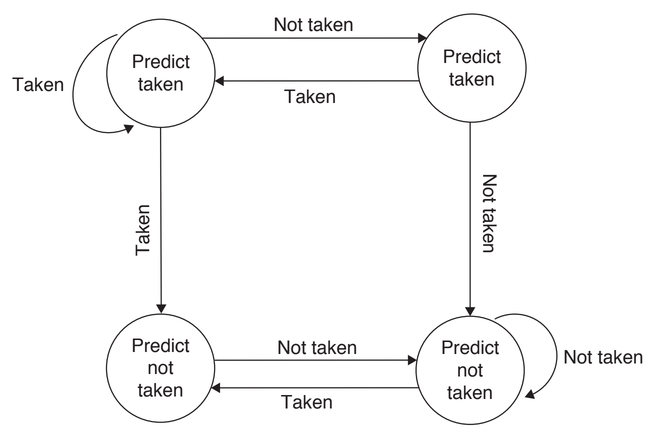


Figure 1 Branch prediction state diagram

- As long as each succeeding conditional branch instruction that is encountered is taken, the decision process predicts that the next branch will be taken.
- If a single prediction is wrong, the algorithm continues to predict that the next branch is taken.
- Only if two successive branches are not taken does the algorithm shift to not taken branch.

Drawback: If the decision is made to take the branch, the target instruction cannot be fetched until the target address, which is an operand in the conditional branch instruction is decoded.

(b) Branch history table: It is a small cache memory associated with the instruction fetch stage of the pipeline.

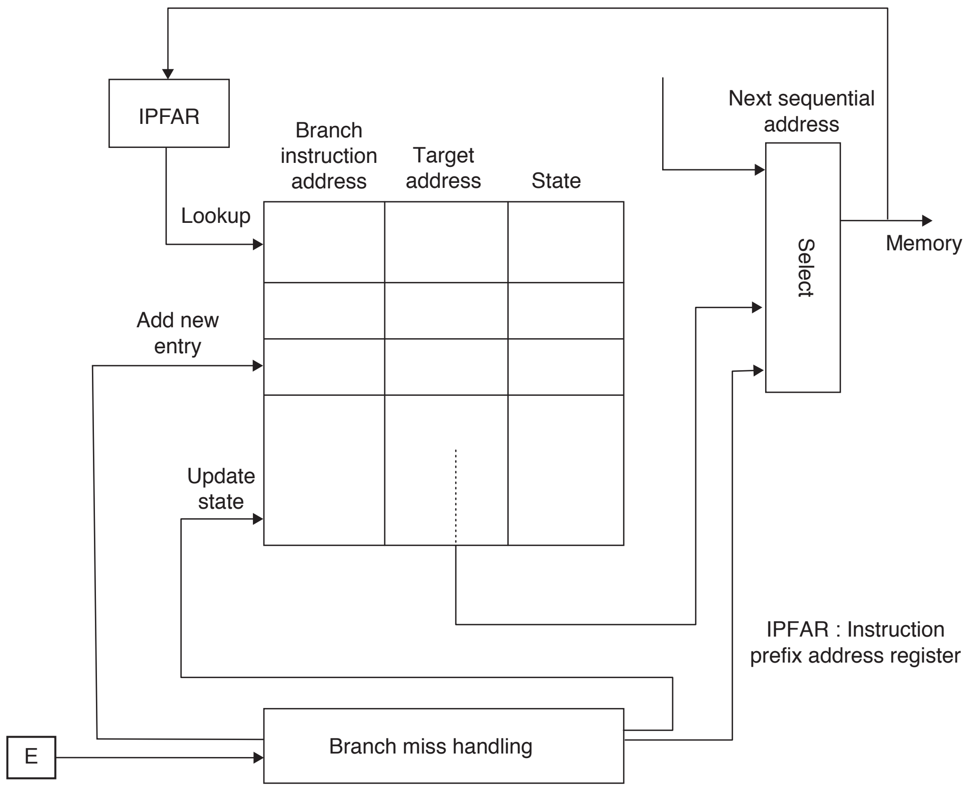

Figure 2 Branch history table

- Each entry in the table consist of three elements:
  1. The address of branch instruction.
  2. Some number of history bits that record the state of use of that instruction.
  3. Information about target instruction.

Delayed branch A complier detects the branch instructions and rearranges the machine language code sequence by inserting useful instructions that keep a pipeline operating without interruptions.

Exercises

Practice Problems I

Directions for questions 1 to 21: Select the correct alternative from the given choices.

Common data for questions 1 and 2: An unpipelined processor with eight number cycle time and pipeline batches with 1 ns latency is given.

1. Find the cycle times of pipelined versions of the processor with 2, 4, 8 and 16 stages if the Data path logic is evenly divided among the pipeline stages.
(A) 5, 3, 2, 1.5 (B) 4, 2, 1, 0.5
(C) 8, 4, 2, 1 (D) 10, 6, 4, 3

2. What is the latency of each of the pipelined versions of the processor?
(A) 4, 2, 1, 0.5 (B) 10, 6, 4, 3
(C) 5, 3, 2, 1.5 (D) 10, 12, 16, 24

3. A 4-stage pipeline has the stage delays as 110, 120, 130, and 140 nanoseconds respectively. Registers that are used between the stages have a delay of 2 nanoseconds each. Assuming constant clocking rate. Find the total time taken to process 1000 instructions on this pipeline.
(A) 7.1 ms (B) 14.24 ms
(C) 28 ms (D) 2000 ms

4. Consider a pipelined processor with the following four stages:
IF: instruction fetch
ID: Instruction decode
EX: Execute
WB: Write back
The IF, ID and WB stages takes one clock cycle each to complete the operation. The number of clock cycles for EX stage depends on the instruction; for I_1 and I_3 one clock cycle is needed and for I_2 three clock cycles are needed. Find the number of clock cycles taken to complete the following sequence of instructions?

I_1:	ADD R_0,	R_1,	R_2	$R_0 \leftarrow R_1 + R_2$
I_2:	MUL R_2,	R_3,	R_4	$R_2 \leftarrow R_3 \times R_4$
I_3:	SUB R_4,	R_5,	R_6	$R_4 \leftarrow R_5 - R_6$

(A) 7 (B) 8
(C) 6 (D) 9

5. A CPU has five stage pipelines and runs at 1 GHz frequency. Instruction fetch happens in the first stage of the pipeline. A conditional branch instruction computes the target address and evaluates the condition in the third stage of the pipeline. The processor stops fetching new instructions following a conditional branch until the branch outcome is known. A program executes 10^9 instructions. Out of which 10% are conditional branches. If each instruction takes one cycle to complete on average then find the total execution time of the program?

(A) 1 sec (B) 1.2 sec
(C) 1.4 sec (D) 1.8 sec

6. Consider a four stage pipeline processor, number of cycles needed by the four instructions I_1, I_2, I_3 and I_4 in stages S_1, S_2, S_3 and S_4 are shown below:

	S_1	S_2	S_3	S_4
I_1	2	1	1	1
I_2	1	3	2	2
I_3	2	1	1	3
I_4	1	2	2	2

What is the number of cycles needed to execute the instructions in the order:
$I_1 : I_2 : I_3 : I_4$

(A) 8 (B) 12
(C) 14 (D) 15

7. A non-pipelined system takes 50 ns to process a task; the same task can be processed in a six-segment pipeline with a clock cycle of 10 ns. Speedup ratio of 100 tasks for pipeline is

(A) 1.62 (B) 3.21
(C) 4.76 (D) 8.21

8. Consider a pipelined processor with the following four stages:
IF: Instruction fetch
ID: Instruction decode
EX: Execute
WB: Write back

The IF, ID and WB stages takes one clock cycle each to complete the operation. The number of clock cycles for EX stage depends on the instruction; for I_1 and I_3 one clock cycle is needed and for I_2 three clock cycles are needed. The number of clock cycles taken to complete the following sequence of instructions is

I_1:	ADD R_0, R_1, R_2,	$R_0 \leftarrow R_1 + R_2$
I_2:	MUL R_2, R_0, R_4,	$R_2 \leftarrow R_0 \times R_4$
I_3:	SUB R_4, R_5, R_2,	$R_4 \leftarrow R_5 - R_2$

(A) 7 (B) 8
(C) 9 (D) 10

9. Following are the sequence of stages in a pipeline CPU:
(1) IF: Instruction fetch from instruction memory
(2) RD: Instruction decode and register read
(3) EX: Execute ALU operation for data and address computation
(4) MA: Data memory access, for write access, the register read at RD stage is used.
(5) WB: Register write back

Consider the following sequence of instructions:
LOAD R_1, M[loc]
ADD R_1, R_1, R_1
ADD R_2, R_1, R_2
Let each stage take one clock cycle.

What is the number of clock cycles taken to complete the above sequence of instructions starting from the fetch of first instruction?

(A) 18 (B) 15
(C) 13 (D) 10

10. Which of the following can cause a hazard for a pipelined CPU with a single ALU?
(i) The $(j + 1)^{st}$ instruction uses the result of the j^{th} instruction as an operand.
(ii) The j^{th} and $(j + 1)^{st}$ instructions require the ALU at the same time.
(iii) The execution of a conditional jump instruction.
(iv) The execution of non-conditional jump instruction.

(A) (i) and (ii) (B) (ii) and (iii)
(C) (i), (ii) and (iii) (D) (i), (ii), (iii) and (iv)

11. Given an unpipelined processor with a 10 ns cycle time and pipeline latches with 0.5 ns latency, how many stages of pipelining are required to achieve cycle time of 2 ns?

(A) 5.5 (B) 6.67
(C) 7 (D) 6

12. In a 4-stage pipeline,
IF – instruction fetches
ID – instruction decode and fetch operands
EX – Execute
WB – write back
ADD, SUB take one clock cycle, MUL take three clock cycles. Then for
ADD R_2, R_1, R_0 $R_2 \leftarrow R_1 + R_0$
MUL R_4, R_3, R_2 $R_4 \leftarrow R_3 * R_2$
SUB R_6, R_5, R_4 $R_6 \leftarrow R_5 - R_4$
Number of clock cycles required using operand forwarding technique are

(A) 8 (B) 12
(C) 10 (D) 14

13. Consider an instruction sequence of length 'n' that is streaming through a K-stage instructions pipeline. Let P be the probability of encountering a conditional or

unconditional branch instruction and let q be the probability that execution of a branch instruction I_B causes a jump to a non-consecutive address. Assume that each such jump requires the pipeline to be cleared, destroying all ongoing instruction processing, when I_B emerges from the last stage. Also assume that T is the cycle time. Then which of the following expression correctly specifies the time required for this pipeline?
(A) $pqnk\tau + (1 - pq)\,[K + (n - 1)]\tau$
(B) $(1 - pq)\,[k + (n - 1)]\tau + pqn\tau$
(C) $pqnk\tau + (1 - pq)\,n[k + (n - 1)]\tau$
(D) $pqn + (1 - pq)n\,[k + (n - 1)]\tau$

14. If T_m is maximum stage delay of an m-stage pipeline with time delay of the latch is d then cycle time is
(A) T_m/d (B) $T_m + d$
(C) $2T_m + d$ (D) $T_m \times d$

15. Pipelining is a general technique for increasing processor ____ without requiring large amounts of extra hardware.
(A) turnaround time (B) waiting time
(C) latency (D) throughput

16. A 4-stage instruction pipeline executes a 100 instruction program. The probability of occurrence of a conditional or unconditional branch is 0.4 and the probability of execution of a branch instruction I_B causing a jump to a non-consecutive address is 0.1. Then the speed up factor for the instruction pipeline compared to execution without pipeline is
(A) 2.14 (B) 6.23
(C) 3.21 (D) 3.48

17. A non-pipelined processor has a clock rate of 2.5GHz and an average cycles per instruction of 4. An upgrade to the processor introduces a five stage pipeline. However, due to internal pipeline delays, such as latch delay, the clock rate of the new processor has to be reduced to 2GHz. What is the MIPS rate for each of these processors respectively.
(A) 625, 400 MIPS (B) 625, 2000 MIPS
(C) 3125, 2000 MIPS (D) 3125, 400 MIPS

18. Consider the following sequence of instructions:
I_1: MUL R_1, R_2 $R_1 \leftarrow R_1 * R_2$
I_2: SUB R_3, 1 $R_3 \leftarrow R_3 - 1$
I_3: ADD R_3, R_4 $R_3 \leftarrow R_3 + R_4$
I_4: BEZ Target Branch if zero
I_5: MOVE R_3,10 $R_3 \leftarrow 10$
⋮
Target:
Which of the following instruction will be placed in delayed slot to reduce penalty in a 6-stage pipeline? (Assume that the branch outcome will be known during 5th stage)
(A) I_1 (B) I_2
(C) I_3 (D) I_5

19. Consider the following sequence of instructions:
ADD R_1, R_2 $R_1 \leftarrow R_1 + R_2$
BEZ Target Branch if Zero
MUL R_3, R_4 $R_3 \leftarrow R_3 * R_4$
MOVE R_1,10 $R_1 \leftarrow 10$
⋮
Target:
Assume that this program executed on a 6-stage pipelined processor and each stage required 1 clock cycle.
Let us suppose that "branch not taken" Prediction is used but the prediction is not fulfilled, then the penalty will be (branch outcome is known at 5th stage)
(A) 1 clock cycle (B) 2 clock cycles
(C) 3 clock cycles (D) 4 clock cycles

20. Suppose 40% of the instructions are loads and half the time they are followed by instruction that depends on value loaded. If this hazard causes single cycle delay, how must faster is ideal pipelined machine (CPI = 1) than real one? (Ignore other stalls)
(A) 1 time (B) 1.2 times
(C) 1.5 times (D) 1.15 times

21. Assume that a pipelined processor has three categories of instructions: Branch, load/store, other. If it is a branch instruction it will take 3 clock cycles, if it is a load/store instruction it will take 4 clock cycles and all other instructions require 6 clock cycles. A program consisting of 10% Branch instructions, 10% of load/store instructions is executed on this processor. Then the number of clock cycles required for the execution of the program is
(A) 2.45 (B) 3.61
(C) 4.66 (D) 5.5

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. The time required for the five functional units, which operated in each of the five cycles are 10 ns, 7 ns, 10 ns, 10 ns and 8 ns. Assume that pipelining add 1 ns of overhead. The speed up of pipeline compared to unpipeline is
(A) 4.5 times (B) 1.1 times
(C) 4.1 times (D) 2.4 times

2. Which of the following is a technique of decomposing a sequential process into sub operations with each subprocess being executed in a special dedicated segment that operates concurrently with each other?
(A) Straight line sequencing
(B) Random sequencing
(C) Pipelining
(D) Serial execution

3. Which of the following statements is incorrect?
(A) Latency is the number of time units between two initiations in a pipelined architecture.
(B) If initiations are of different but fixed reservation tables, the architecture is known as static pipelined configuration.
(C) A collision in a pipelined architecture is an attempt by two different initiations to use the same stage at the same time.
(D) None of the above

4. Which of the following technique is used in a pipelined processor, when there is a conditional branch?
(A) Loop butter (B) Branch prediction
(C) Delayed Branch (D) All of the above

5. Which of the following cases, leads to a pipelined computer architecture?
(A) The evaluation of each basic function is relatively independent of the previous one.
(B) The sub-functions are closely related to each other.
(C) The evaluation of each sub function requires approximately the same sequence.
(D) All of the above

6. The performance of a pipelined processors is degraded if
(A) the pipeline stages have different delays.
(B) consecutive instructions are dependent on each other.
(C) the pipeline stages share hardware resources.
(D) All of the above

7. The following is a limit on how much the performance of a processor can be improved using pipelining:
(A) the number of pipeline stages
(B) data dependencies
(C) branch delays
(D) All of the above

8. A pipeline processor consists of a sequence of 'm' data processing circuits called ____, which collectively perform a single operation on a stream of data operands passing through them.
(A) stages (B) pipelines
(C) latches (D) None of the above

9. A five-stage pipelined CPU has the following sequence of stages:
IF – Instruction fetch from memory
RD – Decode instruction
EX – Execute
MA – Data memory access
WB – Register write back

Consider the following instruction sequence:
I_1: Load R_0 $\quad R_0 \Leftarrow M$
I_2: ADD R_1, $\quad R_1\, R_1 \Leftarrow R_1 + R_1$
I_3: SUB R_2, $\quad R_3\, R_2 \Leftarrow R_2 - R_3$

Each stage takes one clock cycle.
Number of clock cycles to execute the program is
(A) 8 (B) 10
(C) 7 (D) 15

Common data for questions 10 and 11: Given an unpipelined processor with a 10 number cycle time and pipeline latches with 0.5 ns latency.

10. Which are the cycle times of pipelined versions of the processors with 2, 4, 8 and 16 stages if the data path logic is evenly divided among the pipeline stages?
(A) 5.0, 3.0, 1.5, 1.0
(B) 5.5, 3.0, 1.75, 1.125
(C) 4.0, 5.0, 6.0, 7.0
(D) None of the above

11. What is the latency of each of the pipelined versions of the processor with 2, 4, 8 and 16 stages?
(A) 10, 11, 12, 14 ns
(B) 10, 10, 11, 11 ns
(C) 11, 12, 14, 18 ns
(D) None of the above

12. Assume an unpipelined processor has a 1 ns clock cycle and it uses 5 cycles for ALU operations and branches. And 6 clock cycles for memory operations. A program has 40%, 30%, and 20% of ALU operations, branch instructions and memory operations respectively. If we are using pipelining it adds 0.2 ns overhead. Then what is the speedup of pipelining compared to unpipelined processor?
(A) 1.2 (B) 3.91
(C) 4.7 (D) 2.5

13. Consider a five-stage pipeline processor in which each instructions on an average has 2 clock cycle stalls. Then the speed up of this pipelined processor compared to an unpipelined processor is
(A) 2.5 (B) 1.67
(C) 0.4 (D) 5

14. Pipelining strategy is called to implement
(A) instruction execution
(B) instruction prefetch
(C) instruction decoding
(D) instruction manipulation

15. If an Instruction 'j' tries to read a source operand before instruction 'i' writes it. Then it is a ____ type of hazard.
(A) WAR (B) RAW
(C) WAW (D) None of these

16. What is the average instruction processing time of a five-stage instruction pipeline for 32 instructions if conditional branch instructions occur as follows: I_2, I_5, I_7, I_{25}, I_{27}.
(A) 1.97 (B) 1.67
(C) 1.75 (D) 1.25

17. Consider the execution of 1000 instructions on a five-stage pipeline machine. Then the speed-up due to the use of pipelining given that the probability of an instruction being a branch is 0.2.
(A) 1.77 (B) 2.6
(C) 2.77 (D) 3.2

18. If an instructions following a branch (taken or not taken) have a dependency on the branch and cannot be executed until the branch is executed, then the dependency is
(A) True data dependency
(B) Procedural dependency
(C) Resource conflict
(D) Output dependency

19. 'A two-stage instruction pipeline unlikely to cut the instruction cycle time in half, compared with the use of no pipeline.' The statement is
(A) Always true (B) Always False
(C) Can't predict (D) Some times true

20. Write after read dependency is also known as
(A) True dependency (B) Anti-dependency
(C) Output dependency (D) Inverse dependency

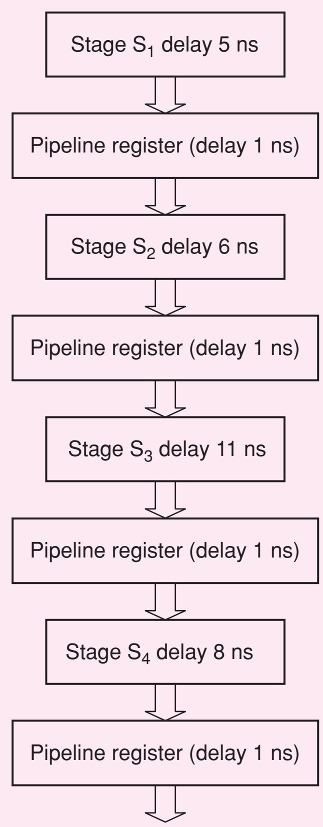
Previous Years' Questions

1. Consider a 6-stage instruction pipeline, where all stages are perfectly balanced. Assume that there is no cycle time overhead of pipelining. When an application is executing on this 6-stage pipeline, the speedup achieved with respect to non-pipelined execution if 25% of the instructions incur 2 pipeline stall cycles is _____. **[2014]**

2. Consider the following processors (ns stands for nano-seconds). Assume that the pipeline registers have zero latency.
P1: Four-stage pipeline with stage latencies 1 ns, 2 ns, 2 ns, 1 ns.
P2: Four-stage pipeline with stage latencies 1 ns, 1.5 ns, 1.5 ns, 1.5 ns.
P3: Five-stage pipeline with stage latencies 0.5 ns, 1 ns, 1 ns, 0.6 ns, 1 ns.
P4: Five-stage pipeline with stage latencies 0.5 ns, 0.5 ns, 1 ns, 1 ns, 1.1 ns.
Which processor has the highest peak clock frequency? **[2014]**
(A) P1 (B) P2
(C) P3 (D) P4

3. An instruction pipeline has five stages, namely, instruction fetch (IF), instruction decode and register fetch (ID/RF), instruction execution (EX), memory access (MEM), and register write back (WB) with stage latencies 1 ns, 2.2 ns, 2 ns, 1 ns, and 0.75 ns, respectively (ns stands for nano seconds). To gain in terms of frequency, the designers have decided to split the ID/RF stage into three stages (ID, RF1, RF2) each of latency 2.2/3 ns. Also, the EX stage is split into two stages (EX1, EX2) each of latency 1 ns. The new design has a total of eight pipeline stages. A program has 20% branch instructions which execute in the EX stage and produce the next instruction pointer at the end of the EX stage in the old design and at the end of the EX2 stage in the new design. The IF stage stalls after fetching a branch instruction until the next instruction pointer is computed . All instructions other than the branch instruction have an average CPI of one in both the designs. The execution times of this program on the old and the new design are *P* and *Q* nanoseconds, respectively. The value of *P*/*Q* is _____. **[2014]**

4. Consider an instruction pipeline with four stages (S_1, S_2, S_3 and S_4) each with combinational circuit only. The pipeline registers are required between each stage and at the end of the last stage. Delays for the stages and for the pipeline registers are as given in the figure.



What is the approximate speed up of the pipeline in steady state under ideal conditions when compared to the corresponding non-pipeline implementation? **[2011]**

(A) 4.0 (B) 2.5
(C) 1.1 (D) 3.0

5. Register renaming is done in pipelined processors **[2012]**
(A) as an alternative to register allocation at compile time
(B) for efficient access to function parameters and local variables
(C) to handle certain kinds of hazards
(D) as part of address translation

6. Consider an instruction pipeline with five stages without any branch prediction: Fetch Instruction (FI), Decode Instruction (DI), Fetch Operand (FO), Execute Instruction (EI) and Write Operand (WO). The stage delays for FI, DI, FO, EI and WO are 5 ns, 7 ns, 10 ns, 8 ns and 6 ns, respectively. There are intermediate storage buffers after each stage and the delay of each buffer is 1 ns. A program consisting of 12 instructions $I_1, I_2, I_3, \ldots, I_{12}$ is executed in this pipelined processor. Instruction I_4 is the only branch instruction and its branch target is I_9. If the branch is taken during the execution of this program, the time (in ns) needed to complete the program is **[2013]**
(A) 132 (B) 165
(C) 176 (D) 328

Common data for Questions 7 and 8: Delayed branching can help in the handling of control hazards

7. For all delayed conditional branch instructions, irrespective of whether the condition evaluates to true or false **[2008]**
(A) The instruction following the conditional branch instruction in memory is executed
(B) The first instruction in the fall through path is executed
(C) The first instruction in the taken path is executed
(D) The branch takes longer to execute than any other instruction

8. The following code is to run on a pipelined processor with one branch delay slot:
I_1: ADD $R_2 \leftarrow R_7 + R_8$
I_2: SUB $R_4 \leftarrow R_5 - R_6$
I_3: ADD $R_1 \leftarrow R_2 + R_3$
I_4: STORE Memory $[R_4] \leftarrow R_1$
BRANCH to Label if $R_1 = 0$
Which of the instructions I_1, I_2, I_3 or I_4 can legitimately occupy the delay slot without any other program modification? **[2008]**
(A) I_1 (B) I_2
(C) I_3 (D) I_4

9. A 5 stage pipelined CPU has the following sequence of stages:
IF - Instruction fetch from instruction memory
RD - Instruction decode and register read
EX - Execute: ALU operation for data and address computation
MA - Data memory access - for write access, the register read at RD state is used
WB - Register write back
Consider the following sequence of instructions.
I_1: $L\ R_0$, loc$_1$; $R_0 <= M[\text{loc}_1]$
I_2: $A\ R_0, R_0$; $R_0 <= R_0 + R_0$
I_3: $S\ R_2, R_0$; $R_2 <= R_2 - R_0$
Let each stage take one clock cycle.
What is the number of clock cycles taken to complete the above sequence of instructions from the fetch of I_1?
(A) 8 (B) 10
(C) 12 (D) 15

10. Consider a non-pipelined processor with a clock rate of 2.5 gigahertz and average cycles per instruction of four. The same processor is upgraded to a pipelined processor with five stages; but due to the internal pipeline delay, the clock speed is reduced to 2 gigahertz. Assume that there are no stalls in the pipeline. The speed up achieved in this pipelined processor is ______. **[2015]**

11. Consider the sequence of machine instructions given below:

MUL R_5, R_0, R_1
DIV R_6, R_2, R_3
ADD R_7, R_5, R_6
SUB R_8, R_7, R_4

In the above sequence, R_0 to R_8 are general purpose registers. In the instructions shown, the first register stores the result of the operation performed on the second and the third registers. This sequence of instructions is to be executed in a pipelined instruction processor with the following 4 stages: (1) Instruction Fetch and Decode (IF), (2) Operand Fetch (OF), (3) Perform Operation (PO) and (4) Write back the result (WB). The IF, OF and WB stages take 1 clock cycle each for any instruction. The PO stage takes 1 clock cycle for ADD or SUB instruction, 3 clock cycles for MUL instruction and 5 clock cycles for DIV instruction. The pipelined processor uses operand forwarding from the PO stage to the OF stage. The number of clock cycles taken for the execution of the above sequence of instructions is _______. **[2015]**

12. Consider the following reservation table for a pipeline having the stages S_1, S_2 and S_3.

Time →

	1	2	3	4	5
S_1	X				X
S_2		X		X	
S_3			X		

The minimum average latency (MAL) is ______ **[2015]**

13. Consider the following code sequence having five instructions l_1 to l_5. Each of these instructions has the following format. **[2015]**

OP Ri, Rj, Rk

Where operation *OP* is performed on contents of registers *Rj* and *Rk* and the result is stored in register *Ri*.

l_1: ADD R_1, R_2, R_3
l_2: MUL R_7, R_1, R_3
l_3: SUB R_4, R_1, R_5
l_4: ADD R_3, R_2, R_4
l_5: MUL R_7, R_8, R_9

Consider the following three statements.

S_1: There is an anti-dependence instructions between instructions l_2 and l_5

S_2: There is an anti-dependence between Instructions l_2 and 1_4

S_3: |Within an instruction pipeline an anti-dependence always creates one or more stalls

Which one of the above statements is/are correct?

(A) Only S_1 is true
(B) Only S_2 is true
(C) Only S_1 and S_3 are true
(D) Only S_2 and S_3 are true

14. The stage delays in a 4 - stage pipeline are 800, 500, 400 and 300 picoseconds. The first stage (with delay 800 picoseconds) is replaced with a functionally equivalent design involving two stages with respective delays 600 and 350 picoseconds. The throughput increase of the pipeline is ___ percent. **[2016]**

15. Consider a 3 GHz (gigahertz) processor with a three - stage pipeline and stage latencies τ_1,τ_2 and τ_3 such that $\tau_1 = 3\tau_2/4 = 2\tau_3$. If the longest pipelines stage is split into two pipeline stages of equal latency, the new frequency is ____ GHz, ignoring delays in the pipeline registers. **[2016]**

16. Instruction execution in a processor is divided into 5 stages, *Instruction Fetch* (IF), *Instruction Decode* (ID), *Operand Fetch* (OF), *Execute* (EX), and *Write Back* (WB). These stages take **5, 4, 20, 10**, and **3 nanoseconds (ns)** respective. A pipelined implement action of the processor requires buffering between each pair of consecutive stages with a delay of **2 ns**. Two pipelined implementations of the processor are contemplated:

(i) A navie pipeline implementation (NP) with 5 stages and
(ii) An efficient pipeline (EP) where the OF stage is divided into stages OF1 and OF2 with execution times of **12 ns** and **8 ns** respectively.

The speedup (correct to two decimal places) achieved by EP over NP in executing 20 independent instructions with no hazards is ______. **[2017]**

17. The instruction pipeline of a RISC processor has the following stages: Instruction Fetch (IF), Instruction Decode (ID), Operand Fetch (OF), Perform Operation (PO) and Write back (WB). The IF, ID, OF and WB stages take 1 clock cycle each for every instruction. Consider a sequence of 100 instructions. In the PO stage, 40 instructions take 3 clock cycles each, 35 instructions take 2 clock cycles each, and the remaining 25 instructions take 1 clock cycle each. Assume that there are no data hazards and no control hazards.

The number of clock cycles required for completion of execution of the sequence of instructions is ______. **[2018]**

Chapter 5

Cache and Main Memory, Secondary Storage

LEARNING OBJECTIVES

- *Characteristics of memory system*
- *Memory hierarchy*
- *Locality of reference*
- *Cache memory*
- *Basic operation of cache*
- *Elements of cache design*
- *Replacement algorithm*
- *Secondary storage*
- *Disk*
- *Diskette*
- *Magnetic tape*
- *Optimal memory*

Characteristics of Memory System

1. **Location:** The term refers to whether memory is internal or external to the computer. The location of memory may be
   - Processor
   - Internal (main)
   - External (secondary)
2. **Capacity:** The capacity of internal memory is expressed in terms of bytes. The capacity specified using
   - Word size
   - Number of words
3. **Unit of transfer**
   - For internal memory, the unit of transfer is equal to the number of data lines into and out of the memory module. The unit of transfer need not equal a word or an addressable unit.
   - For external memory, data are often transferred in much larger units than a word, and these are referred to as blocks.
4. **Access method:** The various methods of accessing units of data are

   (i) Sequential access: Memory is organized into units of data, called records.

   Example: Magnetic tapes

   (ii) Direct access: Individual blocks or records have a unique address based on physical location.

   Example: Magnetic disks

   (iii) Random access: Each addressable location in memory has a unique, physically wired-in addressing mechanism. The time to access a given location is independent of the sequence of prior accesses and is constant.

   Example: Main memory

   (iv) Associative: This is a random access type of memory that enables one to make a comparison of desired bit locations within a word for a specified match.
5. **Performance:** Three performance parameters are:

   (i) Access time (latency):
   - For random access memory, this is the time it takes to perform a read or write operation.
   - For non-random-access memory, access time is the time it takes to position the read-write mechanism at the desired location.

   (ii) Memory cycle time: For a random access memory it consists of the access time plus any additional time required before a second access can commence.

   (iii) Transfer rate: This is rate at which data can be transferred into or out of memory unit.

For Random access memory,

$$\text{Transfer rate} = \frac{1}{\text{Cycle Time}}$$

For non-random access memory, $T_N = T_A + \frac{N}{R}$

Where, T_N = Average time to read or write N-bits.
T_A = Average access time
N = Number of bits
R = Transfer rate in bits per second

6. **Physical type:** The physical type of a memory will be
   i. Semiconductor
   ii. Magnetic
   iii. Optical
   iv. Magneto-optimal
7. **Physical characteristics:** The memory may be
   - Volatile/non-volatile
   - Erasable/non-erasable
8. **Organization:** There is a trade–off among the three key characteristic of memory.
   i. Cost
   ii. Capacity
   iii. Access time

Memory Hierarchy

Consider the following memory hierarchy, which shows the various memory components.

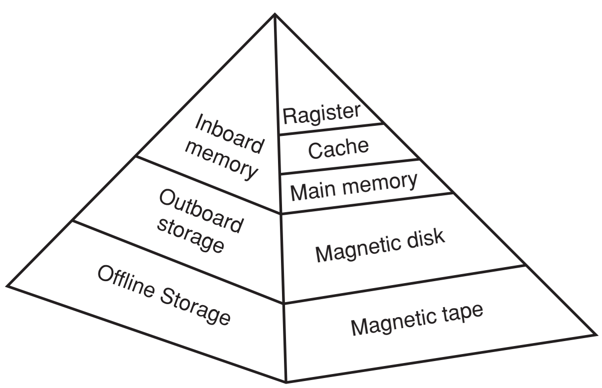

Figure 1 Memory Hierarchy

As one goes down the hierarchy, the following occur:

1. Decreasing cost per bit
2. Increasing capacity
3. Increasing access time
4. Decreasing frequency of access of the memory by the processor.

Locality of Reference

During the course of execution of a program, memory references by the processor, for both instructions and data, tend to cluster. This is referred as principal of locality.

(i) **Registers:** The fastest, smallest and most expensive type of memory consists of the registers internal to the processor.

(ii) **Main memory:** The principal internal memory system of the computer is main memory. Each location in main memory has a unique address.

(iii) **Cache:** Main memory is usually extended with a higher speed, smaller cache. The cache is not visible to the programmer or, indeed, to the processor. It is a device for staging the movement of data between main memory and processor registers to improve performance.

These three forms of memory are volatile and employ semi conductor technology.

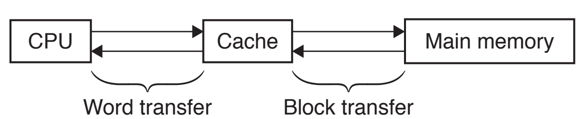
(iv) **Magnetic tapes and disks:** Data are stored more permanently on external mass storage devices, of which the most common are hard disk and removable media.
- External, non-volatile memory is also referred to as secondary or auxiliary memory.
- Used to store program and data files, which are visible to the programmer in the form of files and records.

Cache Memory

The locality of reference property states that over a short interval of time, the address generated by a typical program refer to a few localized areas of memory repeatedly, while the remainder of memory is accessed relatively infrequently (Because of frequent loops and subroutine calls).

If the active portions of the program and data are placed in a fast small memory, the average memory access time can be reduced, thus reducing the total execution time of the program. Such a fast small memory is referred to as a cache memory.

Cache memory is intended to give memory speed approaching that of the fastest memories available and at the same time provide a large memory size at the price of less expensive types of semiconductor memories. The following figure shows the structure of cache/main memory system.



The fundamental idea of cache organization is that by keeping the most frequently accessed instructions and data in the fast memory, the average memory access time will approach the access time of cache.

Basic Operation of Cache

- When the CPU need to access memory, the cache is examined. If the word is found in cache, it is read otherwise main memory is accessed to read the word.

- The performance of cache memory is measured in terms of hit ratio.
- When the CPU refers to memory and find the word in cache, it is called hit.
- If the word is not found in cache and is in Main Memory, it is called miss.

$$\text{Hit ratio} = \frac{\text{hits}}{\text{hits} + \text{misses}}$$

Average access time = $hc + (1 - h)(c + m)$m

Where, $c \rightarrow$ Cache access time

$m \rightarrow$ Main memory access time

$h \rightarrow$ hit ratio

- Let main memory consists of up to 2^n addressable words, with each word having a unique n-bit address.
- For mapping purposes, this memory is considered to consist of a number of fixed length blocks of K words each.

$$\therefore \text{ Number of blocks } (M) = \frac{2^n}{K}$$

- The cache consists of C lines.
- Each line contains K words, plus a tag of a few bits.
- The number of words in a line is referred to as the line size.
- The number of lines is considerably less than the number of main memory blocks i.e., $C << M$.
- Each line includes a tag that identifies which particular block is currently being stored.

  The tag is usually a portion of the main memory address.

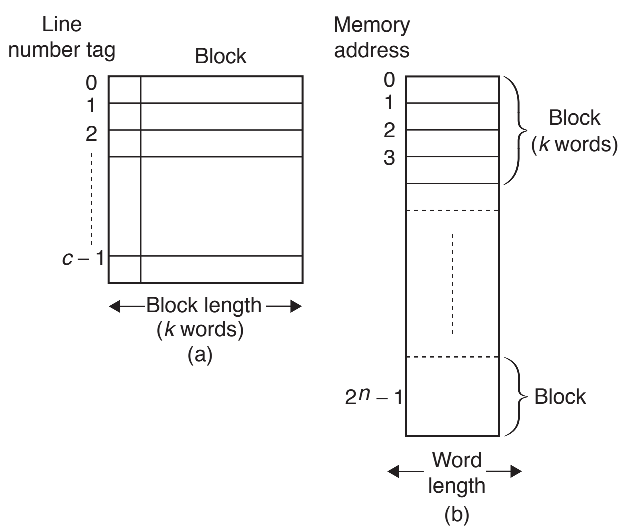


Figure 2 (a) Cache, (b) Main memory

Elements of Cache Design

1. Cache size
2. Mapping function
   - Direct
   - Associative
   - Set-associative
3. Replacement algorithm
4. Write policy
   - Write through
   - Write back
   - Write once
5. Line size
6. Number of caches
   - Single or two level
   - Unified or split

Cache size

The size of the cache to be small enough so that the overall average cost per bit is close to that of main memory alone and large enough so that the overall average access time is close to that of the cache alone.

Mapping function

Because there are fewer cache lines than main memory blocks, an algorithm is needed for mapping main memory blocks into cache lines. Three techniques can be used for mapping.

(i) Direct
(ii) Associative
(iii) Set-associative

Direct mapping Maps each block of main memory into only one possible cache line. Figure 2 illustrates the general mechanism. The mapping is expressed as

$i = j$ modulo m, where

i = cache line number

j = main memory block number

m = number of lines in the cache

For purpose of cache access, each main memory address can be viewed as consisting of three fields.

- The least significand w bits identify a unique word or byte within a block of main memory.
- The remaining s-bits specify one of the 2^s blocks of main memory. The cache logic interpret these s-bits as a tag of s-r bits. (most significand portion)
- A line field of r-bits, to identify one of 2^r lines.

To summarize,

Address length = $(s + w)$ bits

Number of Addressable units = 2^{s+w} words or bytes

Block size = line size = 2^w words or bytes

Number of blocks in main memory = $\frac{2^{s+w}}{2^w} = 2^s$ Number of lines in cache = $M = 2^r$.

Size of Tag = $(s - r)$ bits

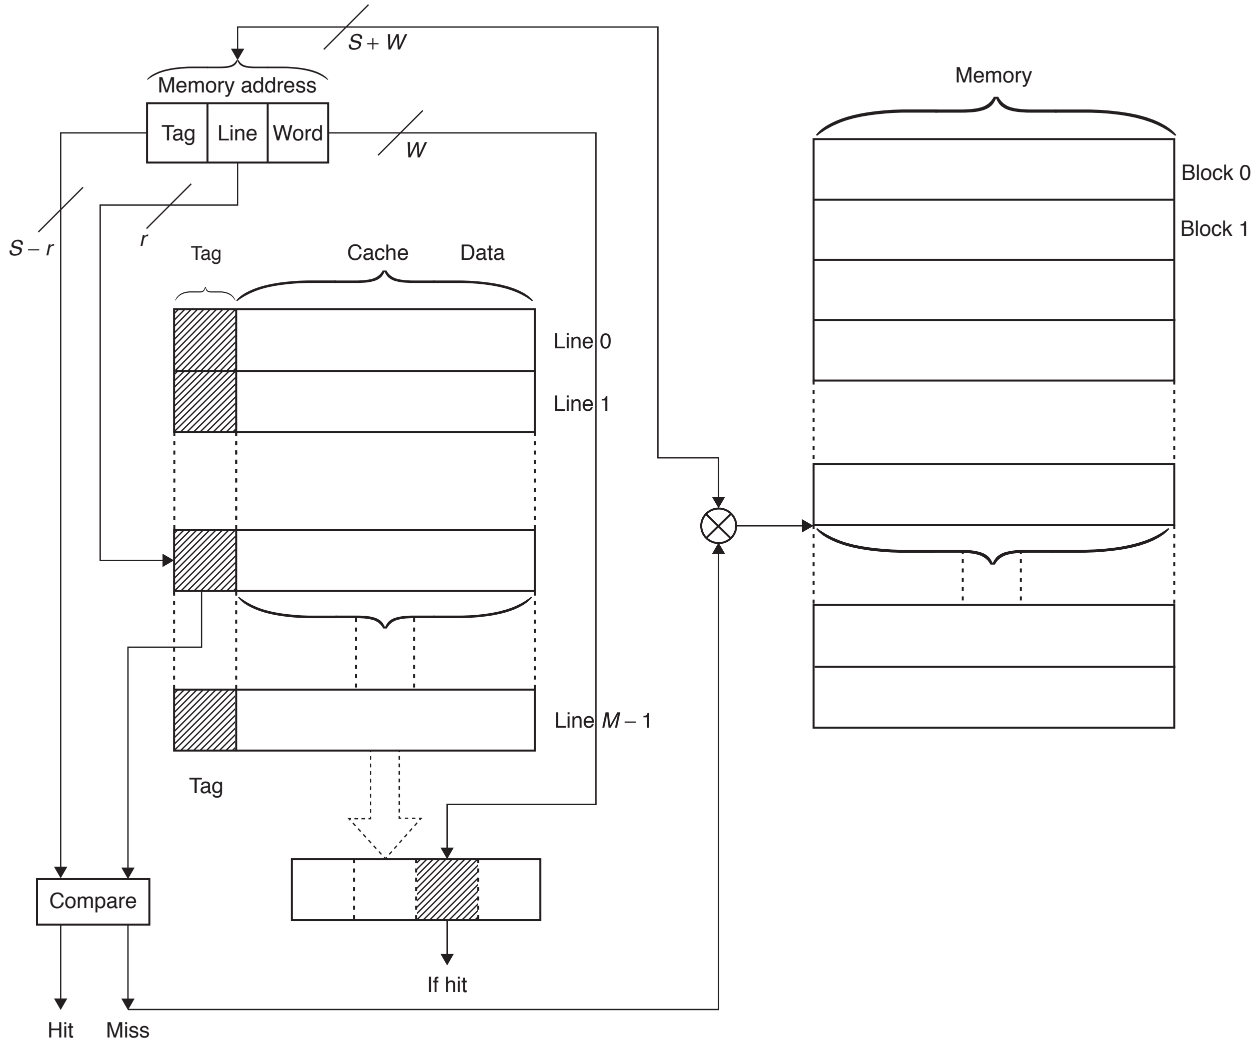

Figure 3 Direct Mapping

The effect of this mapping is that blocks of main memory are assigned to lines of the cache as follows:

Cache Line	Main Memory Blocks Assigned
0	0, m, $2m$, … $2^s - m$
1	1, $m+1$, $2m+1$, … $2^s - m + 1$
.	
.	
.	
.	
$m-1$	$m-1$, $2m-1$, $3m-1$,… $2^s - 1$

Example 1: Let cache capacity = 64 KB
Line size = 4 B
Main memory capacity = 16 MB = 2^{24} B
Using direct mapping, Address length = $s + w$ = 24-bits
Block size = 2^2 B

Number of blocks in main memory $= \dfrac{2^{24}}{2^2} = 2^{22}$

Number of lines in cache $= m = 2^r = \dfrac{2^{16}}{2^2} = 2^{14}$

$\therefore$ Size of tag $= s - r = 22 - 14 = 8$
$\therefore$ Main memory address =

Tag	Line	Word
8	14	2

The mapping becomes

Cache Line	Starting Memory Address of Blocks (Hexa)
0	00000, 010000, … FF0000
1	000004, 010004, … FF0004
.	.
.	.
.	.
.	.
$2^{14} - 1$	00FFFC, 01FFFC,… FFFFFC

Note: No two blocks that map into the same line number have the same tag number.

Advantages:
- Simple and cheap
- The tag field is short; only those bits have to be stored which are not used to address the cache.
- Access is very fast.

Disadvantages: A given block fits into a fixed cache location, i.e., a given cache line will be replaced whenever there is a reference to another memory block which fits to the same line, regardless what the status of the other cache line is.

This can produce a low hit ratio, even if only a very small part of the cache is effectively used.

Associative mapping This technique overcomes the disadvantage of direct mapping by permitting each main memory block to be loaded into any line of the cache. Here the cache control logic interprets a memory address as two fields.

1. Tag
2. Word

Figure shows associative mapping technique:

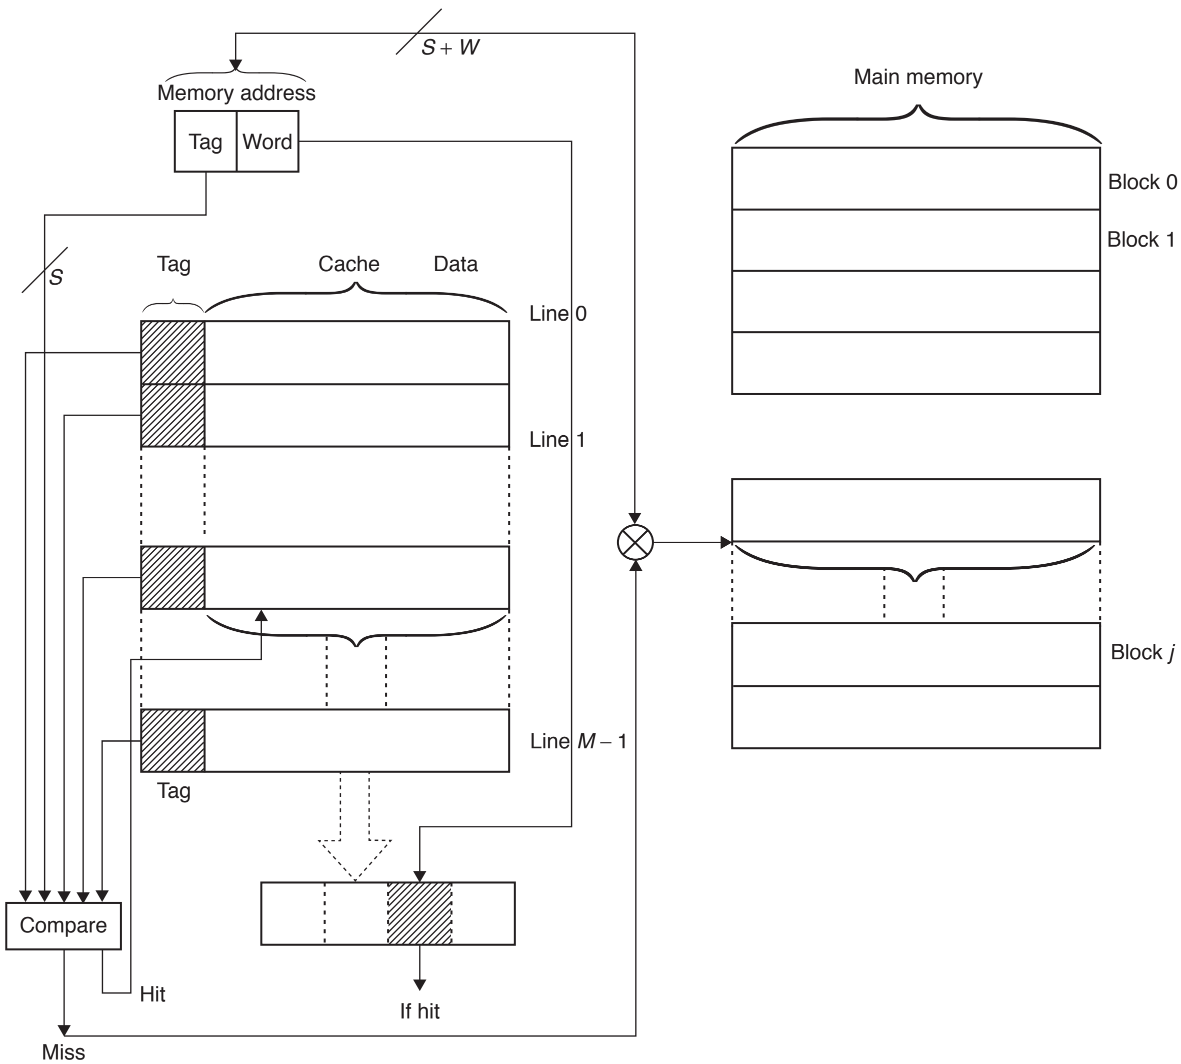

Figure 4 Associative mapping

To determine whether a block is in the cache, the cache control logic must simultaneously examine every line tag for a match. No field in the address corresponds to line number, so that the number of lines in the cache is not determined by the address format.

To summarize,

Address length = $(s + w)$ bits
Number of addressable units = 2^{s+w} words or bytes
Block size = line size = 2^w words or bytes
Number of blocks in main memory = $\frac{2^{s+w}}{2^w} = 2^S$
Number of lines in cache = undetermined
Size of tag = s-bits

Example 2: Cache size = 64 KB
Line size = 4 B
Main memory capacity = 16 MB

Number of blocks in main memory $= \dfrac{2^{24}}{2^2} = 2^{22}$.

$\therefore$ Size of tag = 24 – 2 = 22-bits

For example, the tag of the hexadecimal main memory address 16339C is 058CE7

Main memory address =

Tag	Word
22	2

Advantages: Associative mapping provides the highest flexibility concerning the line to be replaced when a new block is read into a cache.

Disadvantages:

- Complex
- The tag field is long
- Fast access can be achieved only using high performance associative memories for the cache, which is difficult and expensive.

Set-associative mapping: It exhibits strengths of both the direct and associative approaches and reduces their disadvantages.

Here the cache is divided into V sets, each of which consists of K lines

i.e., $m = V \times K$

$i = j$ modulo V

Where i = cache set number

j = main memory block number

m = number of lines in cache

As there are K lines in each set, this is referred as K-way set associative mapping. The cache control logic interprets a memory address simply as three fields.

1. Tag
2. Set
3. Word

The d set bits specify one of $V = 2^d$ sets. The S-bits of the tag and the set fields specify one of the 2^S blocks of main memory.

Figure 3 shows Set-associative mapping.

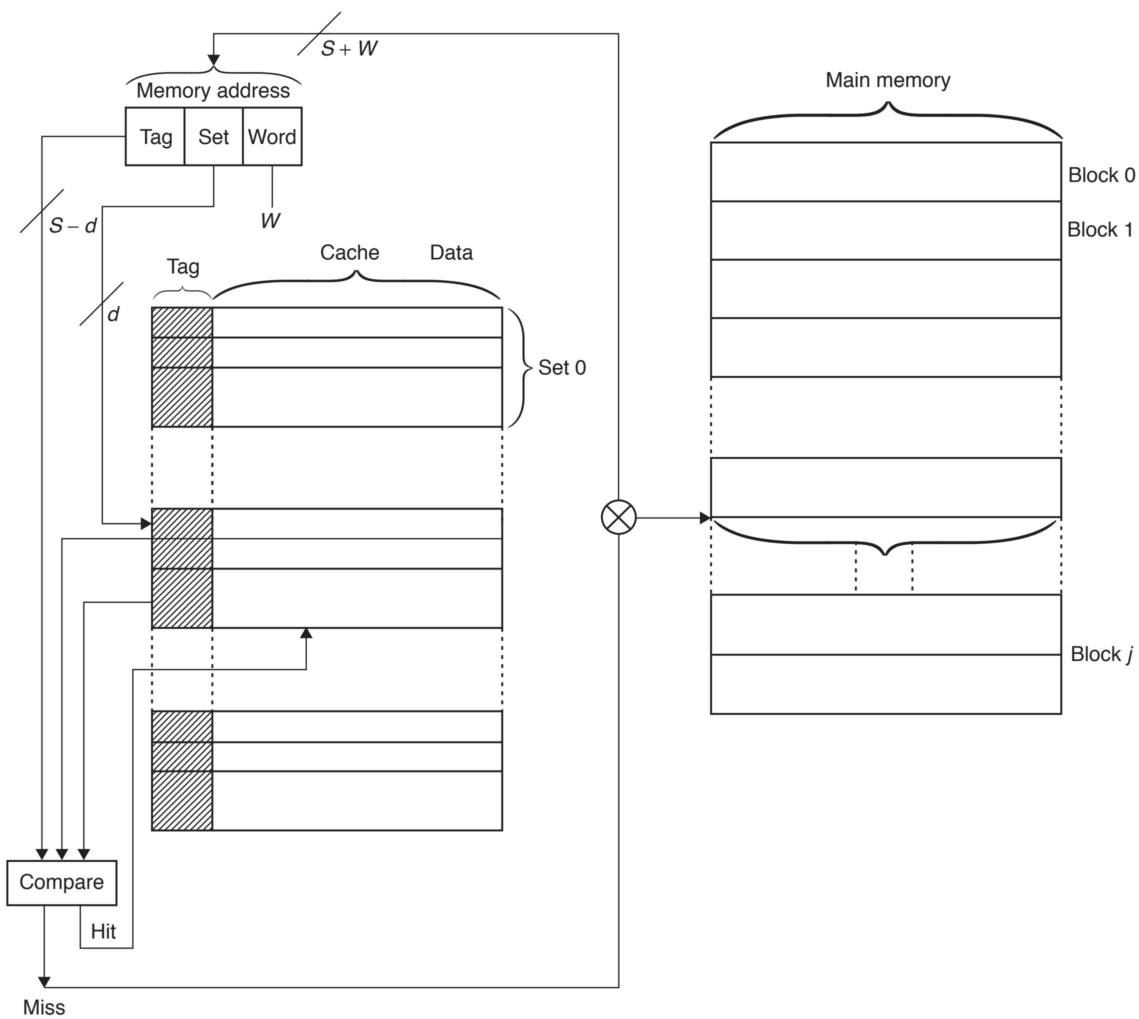

Figure 5 *K*-way set associative cache

Here the tag in a memory address is much smaller and is only compared to the K tags within a single set. To summarize,

Address length = $(s + w)$ bits
Number of Addressable units = 2^{s+w} words or bytes.
Block size = line size = 2^w words or bytes.

Number of blocks in main memory = $\frac{2^{s+w}}{2^w} = 2^s$

Number of lines in set = K
Number of sets $V = 2^d$
Number of lines in cache = $KV = K \times 2^d$
$\therefore$ Size of tag = $(s - d)$ bits

Example 3: Cache capacity = 64 KB
Block size = 4 B
Main memory capacity = 16 MB

Number of blocks in main memory $= \frac{2^{24}}{2^2} = 2^{22}$

For 2-way set associative mapping,
Number of lines in a set $K = 2$
Number of sets = $V = 2^d$

Number of lines in cache = $K \times 2^d = \frac{2^{16}}{2^2}$

$= 2^{14}$
$\Rightarrow \quad 2 \times 2^d = 2^{14}$
$\Rightarrow \quad 2^d = 2^{13}$
$\Rightarrow \quad d = 13$
$\therefore \quad$ Size of Tag = 22 − 13 = 9
Hence main memory address =

Tag	Set	Word
9	13	2

In practice, 2 and 4-way set associative mapping are used with very good results. Larger sets do not produce further significant performance improvement.

If a set consist of a single line, i.e., it is direct mapping; If there is one single set consisting of all lines i.e., it is associative mapping.

Replacement algorithms

Once the cache has been filled, when a new block is brought into the cache, one of the existing blocks must be replaced. For direct mapping, there is only possible line for any particular block, and no choice is possible.

For associative and set associative techniques, a replacement algorithm is needed. Four of the most common replacement algorithms are

(i) LRU (Least recently used): Replaces the block in the set that has been in the cache longest with no reference to it.
(ii) FIFO (First-in-first-out): Replace the block in the set that has been in the cache longest.
(iii) LFU (Least frequently used): Replace the block in the set that has experienced the fewest references.
(iv) Random

Write policy

When a block that is resident in the cache is to be replaced, there are two cases to consider.

(i) If the old block in the cache has not been altered, then it may be over-written with a new block without first writing out the old block.
(ii) If at least one write operation has been performed on a word in that line of the cache, then main memory must be updated by writing the line of cache out of the block of memory before bringing in the new block.

The write policies are

(a) Write through: All write operations are made to main memory as well as to the cache, ensuring that main memory is always valid.
Drawback: Creates substantial memory traffic

(b) Write back: This technique minimizes memory writes. It updates are made only in the cache. When a block is replaced it is written back to main memory if and only if it is updated.
Drawback: There some portions of main memory are invalid and hence accesses by I/O modules can be allowed only through the cache.

Line size

Larger blocks reduce the number of blocks that fit into a cache. Because each block fetch overwrites older cache contents, a small number of blocks results in data being over written shortly after they are fetched.

As a block becomes larger, each additional word is farther from the requested word, therefore less likely to be needed in the near future.

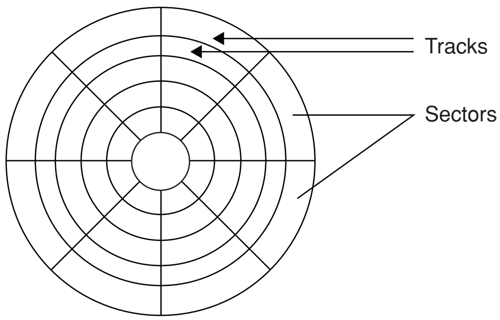
Number of caches

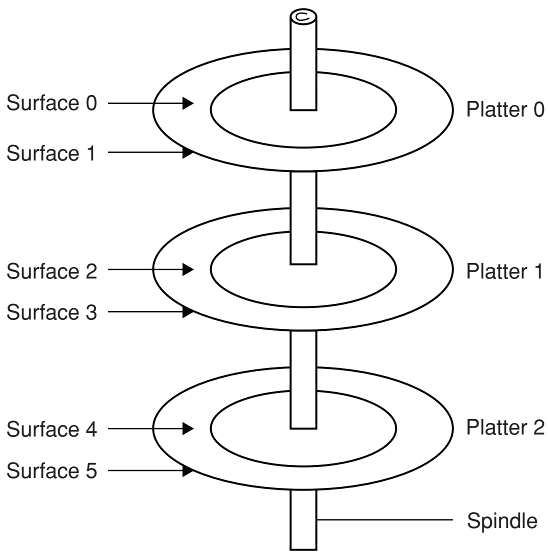
Multilevel caches We may have on-chip cache as well as external cache. This is a two level cache organization, with the internal cache designated as level 1, and external cache designated as level 2.

Secondary Storage

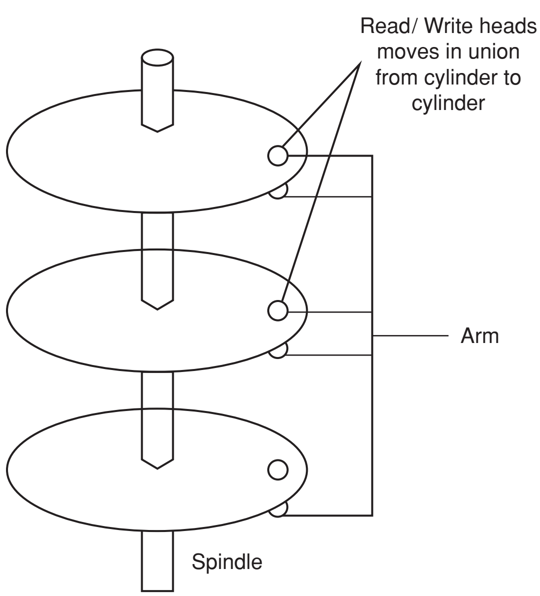
Disk

Disk consists of platters, each with two surfaces. Each surface consists of concentric rings called tracks. Each track consists of sectors separated by gaps.





Disk operation: The disk surface spins at a fixed rotational rate. There is a read/write head attached to the end of the arm and flies over the disk surface on a thin cushion of air. By moving radially the arm can position the read/write head over any track.



Disk access time: Average time to access some target sector:

$T_{ae} = T_{\text{avg seek}} + T_{\text{avg rotation}} + T_{\text{avg transfer}}$

Where $T_{\text{avg seek}}$ is typical 9 ms.

$$T_{\text{avg rotation}} = \frac{1}{2} \times \frac{1}{\text{RPMS}} \times 60 \text{ Sec/1min}$$

$$T_{\text{avg rotation}} = \frac{1}{\text{RPM}} \times \frac{1}{(\text{avg sector/track})} \times 60 \text{ Sec/1min}$$

Notes:

1. Seek time is the Time to position heads over cylinder containing target sectors ($T_{\text{avg seek}}$).
2. Rotational Latency is the time waiting for first bit of target sector to pass under read/write head. ($T_{\text{avg rotation}}$).
3. Transfer Time is the time to read the bits in the target sector ($T_{\text{avg transfer}}$).
   - Data are recorded on the surface of a hard disk made of metal coated with magnetic material.
   - The disks and the drive are usually built together and encased in an air tight container to protect the disk from pollutants such as smoke particle and dust. Several disks are usually started on a common drive shaft with each disk having its own read/write head.

Diskette

Data are recorded on the surface of a floppy disk made of polyester coated with magnetic material.

A special diskette drive must be used to access data stored in the floppy disk. It works much like a record turntable of Gramophone.

Main features

- Direct access
- Cheap
- Portable, convenient to use

Main Standards

- $5^1/_4$ inch capacity ≅ 360 KB/ disk
- $3^1/_2$ inch capacity ≅ 1.44 MB/disk (about 700 pages of A_4 text)

Magnetic Tape

Magnetic tape is made up from a layer of plastic which is coated with iron oxide. The oxide can be magnetized in different directions to represent data. The operation uses a similar principle as in the case of a tape recorder.

Main features

- Sequential access (access time about 1.55)
- High value of storage (50 MB/tape)
- Inexpensive

It is often used for Batch up or archive purpose.

Optimal Memory

CD-ROM (Compact disk ROM): The disk surface is imprinted with microscopic holes which record digital information. When a low-powered power beam shines on the surface, the intensity of the reflected light changes as it encounters a hole. The change is detected by a photo sensor and converted into a digital signal.

- Huge capacity: 775 MB/disk (≈550 diskette)
- Inexpensive replication, cheap production.
- Removable, read only.
- Long access time (could be half a second)

WORM (Write Once Read Memory) CD: A lower beam of modest intensity equipped in the disk drive is used to imprint the hole pattern.

- Good for archival storage by providing a permanent record of large volumes of data.

Erasable Optical Disk: Combination of Laser technology and magnetic surface technique.

- Can be repeatedly written and overwritten.
- High reliability and longer life than magnetic disks.

Exercise

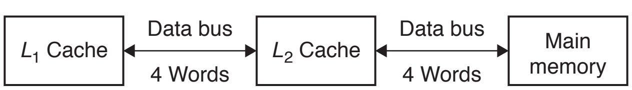
Practice Problems 1

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Find the number of bits in the cache index and tag for a direct mapped cache of size 32 KB with block size of 32 bytes. The CPU generates 48-bit addresses.
(A) 33,15 (B) 15,10
(C) 10,33 (D) 15,33

2. Given the cache access time is 200 ns and the memory access time is 400 ns. If the effective access time is 20% greater than the cache access time, what is the hit ratio?
(A) 80% (B) 20%
(C) 40% (D) 100%

3. A computer system has an L_1 cache, an L_2 cache and a main memory unit connected as shown below. The block size in L_1 cache is 2 words. The block size in L_2 cache is 8 words. The memory access times are 2 nanoseconds, 20 nanoseconds and 200 nanoseconds for L_1 cache, L_2 cache and main memory unit, respectively.



When there is a miss in L_1 cache and a hit in L_2 cache, a block is transferred from L_2 cache to L_1 cache. What is the time taken for this transfer?
(A) 22 ns (B) 44 ns
(C) 66 ns (D) 88 ns

4. In direct memory management, CPU references address of 15-bits. Main memory size is 512 * 8 and cache memory size is 128 * 8. Tag and line are respectively
(A) 9, 7 (B) 7, 9
(C) 15, 7 (D) 7, 15

5. Consider a cache with 64 blocks and a block size of 16 bytes. The byte address of 1200 maps to ____ block number.
(A) 10 (B) 11
(C) 64 (D) 16

6. In a cache memory, cache line is 64 bytes. The main memory has latency of 32 ns and bandwidth of 1 GB/sec. Then the time required to fetch the entire cache line from main memory is
(A) 32 ns (B) 64 ns
(C) 96 ns (D) 128 ns

7. A set associative cache consists of 64 lines or slots divided into four-line sets. Main memory contains 4K blocks of 128 word each. Then the number of bits present in tag, set and word fields are respectively.
(A) 7, 6, 7 (B) 6, 7, 7
(C) 4, 8, 7 (D) 8, 4, 7

8. A 2-way set-associative cache has lines of 32 bytes and a total size of 16 KB. The 32 MB main memory is byte addressable. Then which of the following two memory addresses mapped to same set?
(A) 10D6A32, 035C3A2
(B) 2A36D01, 2A3C530
(C) 10D63A2, 035C3A0
(D) 2A36D08, 0A3C538

9. Let the cache memory capacity is 64 KB and main memory capacity is 16 MB. Let block size is 4 bytes. Then the tag, line, word fields in hexadecimal notation for the main memory address cccccc using direct mapped cache will be
(A) cc, ccc, c (B) cc, 3333, 0
(C) cc, ccc, 0 (D) cc, 333, 30

10. Consider a 32-bit microprocessor that has an on-chip 16 KB four-way set associative cache. Assume that the cache has a line size of four 32-bit words. Then the word in the memory location ABCDE8F8 will be mapped to
(A) 143rd set (B) 815th set
(C) 255th set (D) 0th set

11. Given the following specifications for an external cache memory:
Four-way set associative, Line size of two 16-bit words; Able to accommodate a total of 4K 32-bit words from

main memory. Used with a 16-bit processor that issues 24-bit address. Then the number of bits used to represent set field is
(A) 2-bits (B) 10-bits
(C) 12-bits (D) 14-bits

12. Consider a machine with a byte addressable main memory of 2^{16} bytes and block size of 8 bytes. Assume that a direct mapped cache consisting of 32 lines is used with this machine. Then in what line would bytes with the address 1100 0011 0011 0100 is stored?
(A) slot 3 (B) slot 4
(C) slot 6 (D) slot 12

13. A computer system contains a main memory of 32 K 16-bit words. It also has a 4 K-word cache divided into four line sets with 64 words per line. The processor fetches words from locations 0, 1, 2…, 4351 in that order. It then repeats this fetch sequence 10 more times. The cache is 10 times faster than main memory. Then the improvement resulting from the use of the cache is (assume an LRU policy is used for block replacement)
(A) 0.63 (B) 0.45
(C) 1.21 (D) 2.18

14. Consider an L_1 cache with an access time of 1ns and a hit ratio of $H = 0.95$. Suppose that we can change the cache design such that we increase H to 0.98, but increase access time to 1.5ns. Which of the following condition is met for this change to result in improved performance?
(A) Next level memory access time must be less than 16.67
(B) Next level memory access time must be greater than 16.67
(C) Next level memory access time must be less than 50
(D) Next level memory access time must be greater than 50

15. Consider a single-level cache with an access time of 2.5 ns and a line size of 64 bytes and a hit ratio of $H = 0.95$. Main memory uses a block transfer capability that has a first-word (4 bytes) access time of 50 ns and an access time of 5ns for each word thereafter. What is the access time when there is a cache miss?
(A) 130 ns (B) 149.4 ns
(C) 2.375 ns (D) 8.875 ns

16. The tag, block and word fields of main memory address using direct mapping technique for 2048 main memory blocks, 128 blocks of cache memory and block size of 16:
(A) 4, 7, 4 (B) 7, 4, 4
(C) 11, 7, 4 (D) Data insufficient

17. Let H_1 is level 1 cache hit ratio, H_2 is level 2 cache hit ratio, C_1 is the time required to access Level 1 cache, C_2 is the time required to access Level 2 cache and M is the time required to access Main memory. Then the average access time required by the processor is
(A) $H_1C_1 + (1 - H_1)\, H_2(C_2) + (1 - H_1)\,(1 - H_2)\,(M)$
(B) $H_1C_1 + (1 - H_1)\, H_2(C_1 + C_2) + (1 - H_1)\,(1 - H_2)\,(C_1 + C_2 + M)$
(C) $H_1C_1 + H_1H_2(C_1 + C_2) + H_1H_2(C_1 + C_2 + M)$
(D) $H_1C_1 + (1 - H_1)\, H_2(C_1.C_2) + (1 - H_1)\,(1 - H_2)\,(C_1.C_2.M)$

18. If $p = 2^m$ be the number of lines in cache and $b = 2^n$ be the size of each block, then total words that can be stored in cache memory is given by
(A) 2^{m+n} (B) 2^{m-n}
(C) $m + n$ (D) $p + b$

19. Cache memory enhances
(A) memory capacity
(B) memory access time
(C) secondary storage capacity
(D) secondary storage access time

20. Which of the following property allows the processor to execute a number of clustered locations?
(A) Spatial (B) Temporal
(C) Inclusion (D) Coherence

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. If average access time of CPU is 20 ns, access time of main memory is 110 ns and the cache access time is 10 ns. What is the hit ratio?
(A) 100% (B) 90%
(C) 80% (D) 70%

2. A hard disk spins at 180 revolutions per minute. What is the average rotational latency?
(A) 0.16 sec (B) 0.32 sec
(C) 0.2 sec (D) 0.4 sec

3. A disk pack have 16 surfaces, with 128 tracks per surface and 256 sectors per track. 512 bytes of data are stored in a bit serial manner in a sector. The number of bits required to specify a particular sector in the disk is
(A) 4 (B) 7
(C) 11 (D) 19

4. A disk has 19456 cylinders, 16 heads and 63 sectors per track. The disk spins at 5400 rpm. Seek time between adjacent tracks is 2 ms. Assuming the read/write head is already positioned at track 0, how long does it take to read the entire disk?
(A) 48 min (B) 58 min
(C) 64 min (D) 72 min

5. A certain moving arm disk storage with one head has following specifications:
Number of tracks/recording surface = 200
Disk Rotation Speed = 2400 rpm
Track storage capacity = 62500-bits
The average latency time (assuming that head can move from one track to another only by traversing the entire track) is
(A) 0.125 sec (B) 1.25 sec
(C) 0.0125 sec (D) 12.5 sec

6. In Memory management system, cache memory access time is 100 ns and main memory access time is 200 ns. Number of CPU references is 100 and number of hits is 10. Average access time is
(A) 150 ns (B) 100 ns
(C) 190 ns (D) 280 ns

7. The seek time of disk is 40 m sec. It rotates at the rate of 40 rps. The capacity of each track is 400 words. The access time is
(A) 50 m sec (B) 53 m sec
(C) 60 m sec (D) 63 m sec

8. An Associated cache and one million word main memory are divided into 256 word blocks. How many blocks are there?
(A) 2^8 (B) 2^{12}
(C) 2^{20} (D) 2^{28}

9. The average access time of a disk is
(A) Seek time + Rotational latency time
(B) Seek time
(C) Rotational latency + transfer time + seek time
(D) Rotation latency + transfer time.

10. What will be the size of the memory whose last memory location is FFFF?
(A) 64 k (B) 32 k
(C) 10 k (D) 24 k

11. Data from a cassette tape is obtained by ____ accessing method.
(A) Parallel (B) Serial
(C) Sequential (D) Random

12. For a memory system, the desirable characteristics is/are
(A) Speed and reliability
(B) Durability and compactness
(C) Low power consumption
(D) All of these

13. The memory that has the shortest access time is
(A) Magnetic bubble (B) Magnetic core memory
(C) Cache memory (D) RAM

14. Cache memory
(A) has greater capacity than RAM.
(B) enhances secondary storage access time.
(C) is faster to access than registers.
(D) is faster to access than main memory

15. Consider a disk pack with 16 surfaces 128 tracks per surface and 256 sectors per track. 512 bytes of data are stored in bit and serial manner, Then the capacity of the disk is
(A) 256 MB (B) 256 KB
(C) 512 MB (D) 64 MB

16. Principle of locality justifies the use of
(A) Cache (B) DMA
(C) Disk (D) RAM

17. The main memory of a computer has $2ab$ blocks while cache has $2a$ blocks. If the cache uses the set associative mapping scheme with two blocks per set, then block k of main memory maps to the set:
(A) (k mod b) of the cache (B) (k mod a) of cache
(C) (k mod $2a$) of cache (D) (k mod $2ab$) of cache

18. Which of the following factors do not affect the hit ration of cache?
(A) Block replacement algorithms.
(B) Block frame size
(C) Cycle counts
(D) Main memory size

19. In which of the following mapping function, there is no need of replacement algorithm?
(A) Direct Mapping
(B) Set-associative mapping
(C) Full associative mapping
(D) Both (A) and (B)

20. In a direct mapping, the index field equals to
(A) Sum of tag and word fields
(B) Sum of block and word fields
(C) Sum of tag an block fields
(D) Same as block field

Previous Years' Questions

1. Consider a small two-way set-associative cache memory, consisting of four blocks. For choosing the block to be replaced, use the least recently used (LRU) scheme. The number of cache misses for the following sequence of block addresses is 8, 12, 0, 12, 8 **[2004]**

(A) 2 (B) 3
(C) 4 (D) 5

2. Consider a direct mapped cache of size 32 KB with block size 32 bytes. The CPU generates 32 bit addresses. The number of bits needed for cache indexing and the number of tag bits are respectively. **[2005]**

(A) 10, 17 (B) 10, 22
(C) 15, 17 (D) 5, 17

Common data for questions 3 and 4: Consider two cache organizations: The first one is 32 KB 2-way set associative with 32-byte block size. The second one is of the same size but direct mapped. The size of an address is 32 bits in both cases. A 2-to-1 multiplexer has a latency of 0.6 ns while a k-bit comparator has a latency of k/10 ns. The hit latency of the set associative organization is h_1 while that of the direct mapped one is h_2.

3. The value of h_1 is: **[2006]**

(A) 2.4 ns (B) 2.3 ns
(C) 1.8 ns (D) 1.7 ns

4. The value of h_2 is: **[2006]**

Data for question 5: Consider a machine with a byte addressable main memory of 2^{16} bytes. Assume that a direct mapped data cache consisting of 32 lines of 64 bytes each is used in the system. A 50 × 50 two-dimensional array of bytes is stored in the main memory starting from memory location 1100 H. Assume that the data cache is initially empty. The complete array is accessed twice. Assume that the contents of the data cache do not change in between the two accesses.

5. Which of the following lines of the data cache will be replaced by new blocks in accessing the array for the second time? **[2007]**

(A) line 4 to line 11 (B) line 4 to line 12
(C) line 0 to line 7 (D) line 0 to line 8

6. For inclusion to hold between two cache levels L_1 and L_2 in a multi-level cache hierarchy, which of the following are necessary? **[2008]**

(i) L_1 must be a write-through cache
(ii) L_2 must be a write-through cache
(iii) The associativity of L_2 must be greater than that of L_1
(iv) The L_2 cache must be atleast as large as the L_1 cache

(A) (iv) only (B) (i) and (iv) only
(C) (i), (ii) and (iv) only (D) (i), (ii), (iii) and (iv)

Common data for questions 7, 8 and 9: Consider a machine with a 2-way set associative data cache of size 64K-bytes and block size 16-bytes. The cache is managed using 32-bit virtual addresses and the page size is 4Kbytes. A program to be run on this machine begins as follows:

```
double ARR [1024] [1024] ;
        int i, j;
/* Initialize array ARR to 0.0 */
 for (i = 0; i < 1024; i++)
 for (j = 0; j < 1024; j++)
 ARR [i] [j] = 0.0;
```

The size of double is 8 Bytes. Array ARR is located in memory starting at the beginning of virtual page 0XFF000 and stored in row major order. The cache is initially empty and no pre-fetching is done. The only data memory references made by the program are those to array ARR.

7. The total size of the tags in the cache directory is **[2008]**

(A) 32K-bits (B) 34K-bits
(C) 64K-bits (D) 68K-bits

8. Which of the following array elements has the same cache index as ARR [0] [0]? **[2008]**

(A) ARR [0] [4] (B) ARR [4] [0]
(C) ARR [0] [5] (D) ARR [5] [0]

9. The cache hit ratio for this initialization loop is **[2008]**

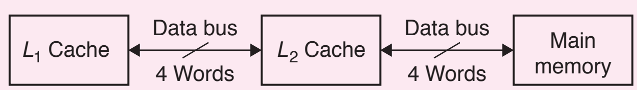
(A) 0% (B) 25%
(C) 50% (D) 75%

10. Consider a 4-way set associative cache (initially empty) with total 16 cache blocks. The main memory consists of 256 blocks and the request for memory blocks is in the following order: **[2009]**
0, 255, 1, 4, 3, 8, 133, 159, 216, 129, 63, 8, 48, 32, 73, 92, 155.

Which one of the following memory block will NOT be in cache if LRU replacement policy is used?

(A) 3 (B) 8
(C) 129 (D) 216

Common data questions 11 and 12: A computer system has an L_1 cache, an L_2 cache, and a main memory unit connected as shown below. The block size in L_1 cache is 4 words. The block size in L_2 cache is 16 words. The memory access times are 2 nanoseconds. 20 nanoseconds and 200 nanoseconds, for L_1 cache, L_2 cache and main memory unit respectively.



11. When there is a miss in L_1 cache and a hit in L_2 cache, a block is transferred from L_2 cache to L_1 cache. What is the time taken for this transfer? **[2010]**

(A) 2 ns (B) 20 ns
(C) 22 ns (D) 88 ns

12. When there is a miss in both L_1 cache and L_2 cache, first a block is transferred from main memory to L_2 cache, and then a block is transferred from L_2 cache to L_1 cache. What is the total time taken for these transfers? **[2010]**

(A) 222 ns (B) 888 ns
(C) 902 ns (D) 968 ns

13. An 8 KB direct-mapped write-back cache is organized as multiple blocks, each of size 32 bytes. The processor generates 32-bit addresses. The cache controller maintains the tag information for each cache block comprising of the following.

1 Valid bit
1 Modified bit
As many bits as the minimum needed to identify the memory block mapped in the cache.

What is the total size of memory needed at the cache controller to store meta-data (tags) for the cache? **[2011]**

(A) 4864 bits (B) 6144 bits
(C) 6656 bits (D) 5376 bits

Common data for questions 14 and 15: A computer has a 256 KB, 4-way set associative, write back data cache with block size of 32 bytes. The processor sends 32 bit addresses to the cache controller. Each cache tag directory entry contains, in addition to address tag, 2 valid bits, 1 modified bit and 1 replacement bit.

14. The number of bits in the tag field of an address is **[2012]**

(A) 11 (B) 14
(C) 16 (D) 27

15. The size of the cache tag directory is **[2012]**

(A) 160 K-bits (B) 136 K-bits
(C) 40 K-bits (D) 32 K-bits
(A) 2.4 ns (B) 2.3 ns
(C) 1.8 ns (D) 1.7 ns

16. In a k-way set associative cache, the cache is divided into v sets, each of which consists of k lines. The lines of a set are placed in sequence one after another. The lines in set s are sequenced before the lines in set $(s + 1)$. The main memory blocks are numbered 0 onwards. The main memory block numbered j must be mapped to any one of the cache lines from **[2013]**

(A) $(j \bmod v) * k$ to $(j \bmod v) * k + (k - 1)$
(B) $(j \bmod v)$ to $(j \bmod v) + (k - 1)$
(C) $(j \bmod k)$ to $(j \bmod k) + (v - 1)$
(D) $(j \bmod k) * v$ to $(j \bmod k) * v + (v - 1)$

17. An access sequence of cache block addresses is of length N and contains n unique block addresses. The number of unique block addresses between two consecutive accesses to the same block address is bounded above by K. what is the miss ratio if the access sequence is passed through a cache of associativity $A \geq K$ exercising least-recently used replacement policy? **[2014]**

(A) n/N (B) $1/N$
(C) $1/A$ (D) K/n

18. A 4-way set -associative cache memory unit with a capacity of 16 KB is built using a block size of 8 words. The word length is 32-bits. The size of the physical address space is 4 GB. The number of bits for the TAG field is _______. **[2014]**

19. In designing a computer's cache system, the cache block (or cache line) size is an important parameter. Which one of the following statements is correct in this context? **[2014]**

(A) A smaller block size implies better spatial locality.
(B) A smaller block size implies a smaller cache tag and hence lower cache tag overhead.
(C) A smaller block size implies a larger cache tag and hence lower cache hit time.
(D) A smaller block size incurs a lower cache miss penalty.

20. Consider a main memory system that consists of 8 memory modules attached to the system bus, which is one word wide. When a write request is made, the bus is occupied for 100 nanoseconds (ns) by the data, address, and control signals. During the same 100 ns, and for 500 ns thereafter, the addressed memory module executes one cycle accepting and storing the data. The (internal) operation of different memory modules may overlap in time, but only one request can be on the bus at any time. The maximum number of stores (of one word each) that can be initiated in 1 millisecond is _______. **[2014]**

21. If the associativity of processor cache is doubled while keeping the capacity and block size unchanged, which one of the following is guaranteed to be NOT affected? **[2014]**

(A) Width of tag comparator
(B) Width of set index decoder
(C) Width of way selection multiplexer
(D) Width of processor to main memory data bus

22. The memory access time is 1 nanosecond for a read operation with a hit in cache, 5 nanoseconds for a read operation with a miss in cache, 2 nanoseconds for a write operation with a hit in cache and 10 nanoseconds for a write operation with a miss in cache. Execution of a sequence of instructions involves 100 instruction fetch operations. 60 memory operand read operations

and 40 memory operand write operations. The cache - hit ratio is 0.9. The average memory access time (in nanoseconds) in executing the sequence of instructions is _______. **[2014]**

23. Assume that for a certain processor, a read request takes 50 nanoseconds on a cache miss and 5 nanoseconds on a cache hit. Suppose while running a program, it was observed that 80% of the processor's read requests result in a cache hit. The average read access time in nanoseconds is _______ **[2015]**

24. A computer system implements a 40-bit virtual address, page size of 8 kilobytes, and a 128-entry translation look-aside buffer (TLB) organized into 32 sets each having four ways. Assume that the TLB tag does not store any process id. The minimum length of the TLB tag in bits is ______ **[2015]**

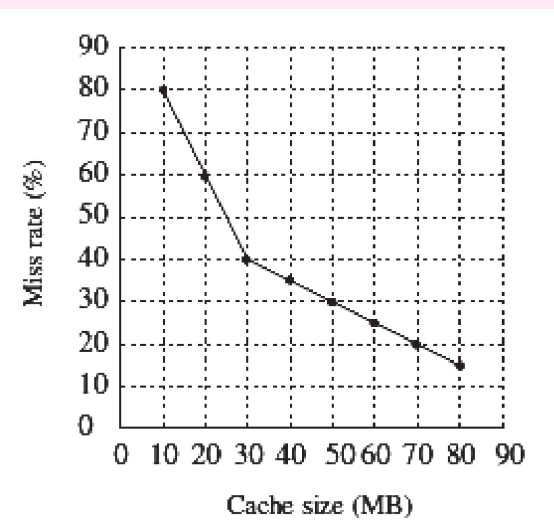
25. Consider a machine with a byte addressable main memory of 2^{20} bytes, block size of 16 bytes and a direct mapped cache having 2^{12} cache lines. Let the addresses of two consecutive bytes in main memory be $(E201F)_{16}$ and $(E2020)_{16}$. What are the tag and cache line address (in hex) for main memory address $(E201F)_{16}$? **[2015]**

(A) E, 201 (B) F, 201
(C) E, E20 (D) 2, 01F

26. The width of the physical address on a machine is 40 bits. The width of the tag field in a 512KB 8-way set associative cache is ____ bits. **[2016]**

27. A file system uses an in - memory cache to cache disk blocks. The miss rate of the cache is shown in the figure. The latency to read a block from the cache is 1 ms and to read a block from the disk is 10ms. Assume that the cost of checking whether a block exists in the cache is negligible. Available cache sizes are in multiples of 10MB.

The smallest cache size required to ensure an average read latency of less than 6 ms is ____ MB. **[2016]**



28. Consider a two-level cache hierarchy with L1 and L2 caches. An application incurs **1.4** memory accesses per instruction on average. For this application, the miss rate of L1 cache is **0.1**; the L2 cache experiences on average 7 misses per 1000 instructions. The miss rate of L2 expressed correct to two decimal places is ______. **[2017]**

29. Consider a 2-way set associative cache with 256 blocks and uses LRU replacement. Initially the cache is empty. Conflict misses are those misses which occur due to contention of multiple blocks for the same cache set. Compulsory misses occur due to first time access to the block. The following sequence of accesses to memory blocks

(0, 128, 256, 128, 0, 128, 256, 128, 1, 129, 257, 129, 1, 129, 257, 129)

is repeated 10 times. The number of *conflict misses* experienced by the cache is _____. **[2017]**

30. A cache memory unit with capacity of N words and block size of B words is to be designed. If it is designed as a direct mapped cache, the length of the TAG field is 10 bits. If the cache unit is now designed as a 16-way set-associative cache, the length of the TAG filed is __________bits. **[2017]**

31. In a two-level cache system, the access times of L_1 and L_2 caches are 1 and 8 clock cycles, respectively. The miss penalty from the L_2 cache to main memory is 18 clock cycles. The miss rate of L_1 cache is twice that of L_2. The average memory access time (AMAT) of this cache system is 2 cycles. The miss rates of L_1 and L_2 respectively are: **[2017]**

(A) 0.111 and 0.056 (B) 0.056 and 0.111
(C) 0.0892 and 0.1784 (D) 0.1784 and 0.0892

32. The read access times and the hit ratios for different caches in a memory hierarchy are as given below.

Cache	Read access time (in nanoseconds)	Hit ratio
I-cache	2	0.8
D-cache	2	0.9
L2-cache	8	0.9

The read access time of main memory is 90 nanoseconds. Assume that the caches use the referred- word-first read policy and the write back policy. Assume that all the caches are direct mapped caches. Assume that the dirty bit is always 0 for all the blocks in the caches. In execution of a program. 60% of memory reads are for instruction fetch and 40% are for memory operand fetch. The average read access time in nanoseconds (up to 2 decimal places) is __________. **[2017]**

33. Consider a machine with a byte addressable main memory of 2^{32} bytes divided into blocks of size 32

bytes. Assume that a direct mapped cache having 512 cache lines is used with this machine. The size of the tag field in bits is________. **[2017]**

34. The size of the physical address space of a processor is 2^P bytes. The word length is 2^W bytes. The capacity of cache memory is 2^N bytes. The size of each cache block is 2^M words. For a K-way set-associative cache memory, the length (in number of bits) of the tag field is: **[2018]**

(A) $P - N - \log_2 K$
(B) $P - N + \log_2 K$
(C) $P - N - M - W - \log_2 K$
(D) $P - N - M - W + \log_2 K$

Test

Computer Organization and Architecture

Time: 60 min.

Directions for questions 1 to 30: Select the correct alternative from the given choices.

1. Which of the following register keeps track of instruction execution sequence?
(A) Accumulator (B) Program counter
(C) Stack pointer (D) Instruction register

2. Consider the following Register Transfer Language:

$$R_1 \leftarrow R_1 + M[R_2 + R_3]$$

Where R_1, R_2 and R_3 are the CPU registers and 'M' is a memory location in primary memory, which addressing mode is suitable for above register transfer language?
(A) Indirect (B) Direct
(C) Indexed (D) Displacement

3. Which of the following is/are advantage(s) of using a multiple-bus architecture over a single-bus architecture?
(i) Multiple-bus architecture reduces propagation delay.
(ii) Multiple-bus architecture reduces bottleneck effects.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

4. Which of the following statement is false with respect to Booth's Multiplication Algorithm?
(i) Corrections required for the final result.
(ii) Sign bit is protected due to internal arithmetic shift.
(iii) More space required to maintain the sum.
(A) (i), (ii) only (B) (ii), (iii) only
(C) (i), (iii) only (D) (i), (ii), (iii)

5. After selective complement of $A = 1100$ with $B = 0101$, the resultant A will be
(A) 0000 (B) 1100
(C) 0101 (D) 1001

6. Which type of shift operation always keeps the sign bit unchanged?
(A) Logical shift (B) Arithmetic shift
(C) Circular shift (D) Any right shift

7. Consider the register transfer language instructions:
$AC \leftarrow M[R_1]$;
$R_1 \leftarrow R_1 + 1$;
Which addressing mode is specified by the instructions?
(A) Register addressing mode
(B) Register indirect mode
(C) Auto-increment mode
(D) Relative mode

8. Which of the following statement is true?
(A) Floating point representation is better than fixed point representation.
(B) Fixed point representation is better than floating point representation.
(C) Datapath is same as ALU.
(D) Both (A) and (C)

9. Which of the following statements correctly specifies about overflow?
(i) When adding two unsigned numbers the carry-out, from the MSB position serves as the overflow indicator.
(ii) Overflow can occur only by adding two signed numbers that have the same sign.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

10. A certain processor supports only the immediate and direct addressing modes. Which of the following programming language features cannot be implemented on this processor?
(A) Pointers (B) Arrays
(C) Records (D) All of these

11. The special purpose storage location(s) used by both ALU and CU are
(A) Decoders (B) Demultiplexers
(C) Registers (D) Buffers

12. Which of the following is a component of the datapath of Von Neumann machine?
(i) Registers
(ii) ALU input bus
(iii) ALU I/O registers
(A) (i), (ii) only (B) (ii), (iii) only
(C) (i), (ii), (iii) (D) None of these

13. Which of the following is/are false with respect to single-bus datapath?
(i) It is simplest and least expensive.
(ii) No limit on the amount of data transfer in a single clock cycle.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

14. If we have shifted the significant to the right by a single position, then
(A) Add one to the exponent
(B) Subtract one from the exponent
(C) Don't change the exponent
(D) Data insufficient

15. In which addressing mode, the effective address of the operand is generated by adding a constant value to the content of a register?
(A) Absolute mode (B) Indirect mode
(C) Immediate mode (D) Index mode

16. What is the number of instructions required to add '*n*' numbers and store the result in memory using only one-address instructions?
(A) n (B) $n - 1$
(C) $n + 1$ (D) independent of n

17. Which unit of a computer system executes program, communicates with and often controls the operation of other subsystems?
(A) CPU (B) ALU
(C) I/O module (D) DMA

18. The multiplicand register and multiplier register of a hardware circuit implementing booth's algorithm have 1001 and 1100 respectively. The resultant will be
(A) 10011100 (B) 00011100
(C) 01101100 (D) 00010010

19. A floating point number has sign bit 0, Excess-64 exponent is 1010100 and fractional part is 0000000000011011. After converting this number to normalized form, the exponent (in decimal) will be
(A) 20 (B) 9
(C) 31 (D) 0

20. In IEEE floating point single precision representation, the number of bits in the fractional part is
(A) 24
(B) 23
(C) 32
(D) Depends on the architecture

21. After multiplying the binary numbers 010111 and 110110 using booth's multiplication algorithm, the resultant will be
(A) –1242 (B) 1242
(C) 230 (D) –230

22. The IEEE standard 754 single precision floating point representation of $(0.000000110110100101)_2$ is.
(A) 0 10000111 11011010010100000000000
(B) 0 01111001 11011010010100000000000
(C) 0 10000110 10110100110100000000000
(D) 0 01111000 10110100101000000000000

23. How many clock cycles are required to perform two-operand operations using one bus datapath?
(A) 1 (B) 2
(C) 3 (D) Can't be determined

24. Which of the following is a rounding mode in IEEE754 standard?
(i) round to 0
(ii) round towards $+\infty$
(iii) round towards $-\infty$
(iv) round to nearest representable number
(A) (i), (iv) only (B) (ii), (iii) only
(C) (i), (ii) only (D) (i), (ii), (iii), (iv)

25. What is the normalized form of $0.00000110 \times 16^{101}$?
(A) 1.10×16^{107} (B) 1.10×16^{95}
(C) 0.110×16^{94} (D) 0.110×16^{106}

26. What is the biased representation of –7, using 4-bits for the bias?
(A) 0111 (B) 1111
(C) 0000 (D) 1001

27. What is the total resultant after adding $A = -7$ and $B = -6$ using signed two's complement representation?
(A) 0100 (B) 11101
(C) 1101 (D) Overflow occurs

28. What is the total number of additions and subtractions required using Booths multiplication algorithm for the multiplier 00011110?
(A) 1 (B) 2
(C) 30 (D) Can't be determined

Common data questions 29 and 30: Consider a 12-bit floating point format in which base $b = 2$, a 5-bit exponent e with a bias = 16 and 6-bit normalized mantissa m. Given two floating point numbers:

A = 0 10001 011011
B = 1 01111 101010

29. After adding A and B, the resultant will be
(A) 1 10001 000000
(B) 1 10001 000001
(C) 0 10001 000000
(D) 0 10001 000001

30. After subtracting B from A, the resultant will be
(A) 1 10001 110101 (B) 0 10001 110101
(C) 1 10001 110110 (D) 0 10001 110110

COMPUTER ORGANIZATION AND ARCHITECTURE TEST I

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. On which of the following factors does the CPU execution time of a program depends?
(i) CPU clock cycles required for a program.
(ii) Clock cycle time.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (iii)

2. Which of the following component(*s*) is not related to the performance of a computer?
(i) CPU execution time for a program
(ii) Instruction count
(iii) Clock cycles per instruction
(iv) Clock cycle time
(A) (ii) only (B) (iii) and (iv)
(C) (i), (iv) (D) None of these

3. Which of the following metrics will be affected by the Instruction set Architecture?
(A) Instruction count (B) Clock rate
(C) CPI (D) All of the above

4. Which of the following combination illustrates the basic design principles of the Hardware design of a computer?
(i) Simplicity favours regularity
(ii) Smaller is faster
(iii) Make the common case fast
(iv) Good design demands good compromises
(A) (i), (iii) (B) (ii), (iv)
(C) (i), (ii), (iv) (D) (i), (ii), (iii), (iv)

5. To convert a 16 - bit number to a 32 - bit equivalent, take the MSB of the number and replicate it to fill the new bits of the 32 - bit number. The old bits are copied into the right portion of the new word. This is known as
(A) Sign expansion
(B) Sign extension
(C) Size casting
(D) Conversion from 16 bit number to 32 bit number is not possible

6. A number in scientific notation that has no leading zeros is called a ——— number.
(A) Floating point (B) Normalized
(C) Overflow (D) De-normalized

7. Consider a 5 - stage pipeline :
1. Instruction fetch 2. Register Read
3. ALU operation 4. Data Access
5. Register write
The time taken for memory access is 200 ns, CPU operation is 200 ns, register read or write is 100 ns. Consider a program with the following kind of instructions:
I_1: Load word
I_2: Store word
I_3: ALU operation
I_4: BEQ (Branch if equal)
If each instruction takes exactly one clock cycle, under ideal conditions, what is the time between I_1 and I_4 with out pipelining?
(A) 800 ns (B) 2100 ns
(C) 2400 ns (D) 600 ns

8. For the previous problem, what is the time between I_1 and I_4 using pipelining?
(A) 2100 ns (B) 2400 ns
(C) 800 ns (D) 600 ns

9. The speed up of pipelined processor compared to non pipelined processor is
——— the number of pipeline stages.
(A) always equal to (B) always less than
(C) less than (D) greater than

10. Pipelining improves the performance by
(A) increasing instruction throughput.
(B) decreasing the execution time of an individual instruction.
(C) Both (A) and (B)
(D) replacing complex instructions with simple instructions.

11. Assume that an enhancement is made to a computer that improves some mode of execution by a factor of 10. This new fast mode is used 50% of the time, measured as a percentage of the execution time when the fast mode is in use. What is the over all speed up we can achieve?
(A) 5.5 (B) 5.2
(C) 4.8 (D) 5.0

12. A bus protocol requires 20 ns for devices to make requests, 10 ns for arbitration and 30 ns to complete each operation. How many operations can be completed per second?
(A) $10 * 10^6$ (B) $17 * 10^6$
(C) $20 * 10^6$ (D) $33 * 10^6$

13. A process has five interrupt lines, numbered 0 – 4 and a policy that low numbered interrupts have priority over higher numbered ones. The processor starts with no interrupts pending and the following sequence of interrupts occurs: 4, 3, 0, 1, 2, 3
Assume that handling any interrupt takes enough time that two more interrupts arrive while the first interrupt is being handled, until all of the interrupts have arrived and that interrupts cannot interrupt each other.
In what order the interrupts are handled ?
(A) 0, 1,2, 3, 3, 4 (B) 4, 3, 0, 1, 2, 3
(C) 4, 0, 1, 3, 2, 3 (D) 4, 0, 1, 2, 3, 3

14. Which of the following mapping technique will provide simpler hardware, simple instruction set and provides all addressing modes?
 (i) Memory mapped I/O
 (ii) Isolated I/O
 (A) (i) only (B) (ii) only
 (C) Both (i) and (ii) (D) Neither (i) nor (ii)

15. Which of the following factors limits the maximum transfer rate of DMA?
 (A) Speed of I/O devices
 (B) Erroneous transfer of block
 (C) Speed of bus
 (D) All the above

16. An address field in an instruction contains decimal value 10. Where is the corresponding operand located for direct addressing?
 (A) In the location '10'.
 (B) '10' is the operand itself.
 (C) '*PC*+ 10' location.
 (D) Data insufficient

17. Suppose we had a block transfer from an I/O device to memory. The block consists of 1024 words and one word can be transferred to/from memory at a time. The number of interrupts needed to transfer a block using DMA is _____.
 (A) 0 (B) 1
 (C) 1024 (D) Unpredictable

18. For the above problem, what is the number of interrupts needed to transfer a block using interrupt driven I/O?
 (A) 0 (B) 1
 (C) 1024 (D) Unpredictable

19. For the Q.no :17, what is the number of interrupts needed to transfer a block using 'programmed I/O'?
 (A) 0 (B) 1
 (C) 1024 (D) Unpredictable

20. The number of times does the processor need to refer to memory when it fetches and executes an indirect address mode instruction (if the instruction is not a branch instruction) is:
 (A) 0 (B) 1
 (C) 2 (D) 3

21. Which of the following is a valid difference between a program branch instruction and a subroutine call?
 (i) A branch instruction changes the contents of PC.
 (ii) A branch instruction do not save the contents of PC before changing, Where as a subroutine will save PC.
 (A) (i) only (B) (ii) only
 (C) Both (i) and (ii) (D) Neither (i) nor (ii)

22. If there are no push and pop operations in an instruction set, then which of the following is TRUE?
 (A) CPU can't able to use the stack.
 (B) CPU can use the stack to perform its internal functions.
 (C) The programmer can use the stack explicitly.
 (D) None of the above

23. Match the following:

Addressing mode		Basic advantage	
1.	Immediate	a.	No memory reference
2.	Direct	b.	Simple
3.	Indirect	c.	Large address space
4.	Register	d.	Flexibility

 (A) 1 – b, 2 – a, 3 – c, 4 – a
 (B) 1 – a, 2 – a, 3 – d, 4 – b
 (C) 1 – a, 2 – b, 3 – c, 4 – a
 (D) 1 – a, 2 – b, 3 – d, 4 – c

24. What is the 8 - bit biased notation representation for –45?
 (A) 01010010 (B) 10101101
 (C) 11010011 (D) 11010010

25. Which of the following are the disadvantages of device polling?
 (i) Polling consumes execution resources even when there are no I/O requests to handle.
 (ii) There is a need to schedule the polling frequency.
 (A) (i) only (B) (ii) only
 (C) Both (i) and (ii) (D) Neither (i) nor (ii)

Answer Keys

1. C	**2.** D	**3.** D	**4.** D	**5.** B	**6.** B	**7.** C	**8.** D	**9.** C	**10.** A
11. A	**12.** B	**13.** D	**14.** A	**15.** D	**16.** A	**17.** B	**18.** C	**19.** A	**20.** D
21. C	**22.** B	**23.** C	**24.** A	**25.** C					

Hints and Explanations

1. CPU execution time for a program = CPU clock cycles for a program * clock cycle time. Choice (C)

2. All the four are the basic measurements at different levels in the computer. Choice (D)

3. The instruction set architecture affects all the three aspects of CPU performance; it affects the instructions needed for a function, the cost in cycles of each instruction and the overall clock rate of the processor.
Choice (D)

4. The design principles of Hardware of a computer are
1. Simplicity
2. Smaller number of registers
3. Commonly occurring things needs to be constant.
4. Some compromises required for good design

Choice (D)

5. 8-bits

1	1	1	1	1	0	0	0

↓ 16 bits

1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0

Choice (B)

7. Without using pipelining the time taken for a single instruction is the sum of the times required by all the stages of the pipeline.
i.e., $IF + RR + ALU + DA + RW$
$= 200 + 100 + 200 + 200 + 100 = 800$ns
Each instruction requires one clock cycle.
Time between I_4 and I_1 is 800 ns * 3(instructions)
= 2400 ns. Choice (C)

8. Using pipelining I_2 will start IF after completion of I_1's IF.
So the maximum stage delay 200 ns is considered as time between I_1 and I_2.
(i.e., any two instructions)
Time between I_1 and I_4 is 3×200 ns = 600 ns.

Choice (D)

9. The speed up of pipelined processor is equal to number of pipeline stages under ideal conditions. But in general, it will be less than the number of stages.

Choice (C)

10. Pipelining improves performance by increasing instruction throughout rather than decreasing the execution time of an individual instruction. Choice (A)

11. Speed of after enhancement
$= 0.5 * 10 + (1 – 0.5)$
$= 5 + 0.5 = 5.5$. Choice (A)

12. Time taken for an operation= 20 ns + 10 ns + 30 ns = 60 ns. Number of operations completed per second
$= \dfrac{1}{60\times10^{-9}}$
$= 17 * 10^6$ operations/sec Choice (B)

13. Lower numbered interrupts have high priority.
Let initially 4 is handled, mean while, 3 and 0 will occur. Give priority to 0.
While 0 is handled, 1 and 2 will occur with 3 also in pending Queue. Next handle 1, 2, 3, 3.
∴ Order is 4, 0, 1, 2, 3, 3. Choice (D)

14. Memory mapped I/O provides
- Simple hardware
- Simple instruction set
- All address modes available. Choice (A)

15. DMA does not use CPU but its transfer rate is limited because of
1. low speed of I/O devices
2. low speed of bus
3. less internal buffering
4. erroneous Disk. Choice (D)

16. In direct addressing mode, the address of operand is directly present in the instruction itself. So location 10 contains the data. Choice (A)

17. DMA will generate an interrupt after completion of block transfer.
∴ One interrupt will be generated. Choice (B)

18. In interrupt driven technique, interrupt will be generated after transfer of every word.
∴ 1024 interrupts. Choice (C)

19. In programmed I/O, no interrupt will be generated.
The CPU will check the status bits.
∴ Zero interrupts. Choice (A)

20 '3' memory references required.
one for fetching instruction and '2' for fetching operand. Choice (D)

21. A branch instruction do not save PC before changing PC, where as a subroutine saves for restoring them later. Choice (C)

22. CPU can use stack even if there are no PUSH and POP instructions. PUSH and POP are used by the programmer. Choice (B)

23. Immediate, Register – No memory reference
Direct – simple.
Indirect – large address space. Choice (C)

24. The bias using 8-bits is 127.
Biased value of –45 is
–45 + 127 = 82 = 01010010. Choice (A)

25. Polling wastes the resources and the frequency of polling also need to be scheduled. Choice (C)

Computer Organization and Architecture Test 2

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Which of the following memory access methods, will accurately predict the amount of time it will take to receive the data after requesting it?
(A) Sequential access (B) Direct access
(C) Random access (D) Both (B) and (C)

2. In which of the following access method, any location can be accessed in a fixed amount of time after specifying its address?
(A) Sequential access (B) Random access
(C) Direct access (D) None of the above

3. Which of the following statement is TRUE with respect to write-through and write-back techniques?
(A) Write-back scheme is faster than write-through.
(B) Write-through improves performance better than write-back.
(C) Write-through is more complex to implement than write-back
(D) All the above

4. Increasing the degree of associativity of a cache memory will
(A) increases the miss rate.
(B) decreases the miss rate.
(C) increases the number of sets.
(D) decreases the number of elements per set.

5. Which of the following address information is required to identify whether a word in the cache corresponds to the requested word or not?
(A) Tag (B) Index
(C) Line number (D) offset

6. Which of the following factors will be better effected because of larger cache memory?
(i) Hit rate (ii) Cost
(iii) Speed (iv) Power consumption
(v) Reliability
(A) (ii), (iv), (v) (B) (ii), (iii)
(C) (i) only (D) (i), (iii), (iv)

7. If the depth of a pipeline increases, then which of the following is true?
(i) Clock frequency increases
(ii) CPI increases
(iii) Branch mis-prediction penalty reduced.
(A) (i), (ii) only (B) (ii), (iii) only
(C) (i), (iii) only (D) (i), (ii), (iii)

8. Which of the following are the necessary conditions for an n-stage pipeline is n times faster than a non pipelined processor?
(A) Equal cycle time (of the stages).
(B) All instructions take equal number of cycles.
(C) No stalls between instructions.
(D) All of the above

9. Which of the following technique is generally used to avoid WAR and WAW hazards?
(A) By executing an instruction only when the operands are available.
(B) By Register renaming.
(C) Delayed pranching.
(D) All the above

10. Assume a memory access to main memory on a cache miss takes 10 ns and a memory access to the cache on a cache hit takes 1 ns. If 90% of the processors memory requests result in a cache hit, what is the average memory access time?
(A) 2 ns (B) 1 ns
(C) 1.9 ns (D) 1.4 ns

11. Consider the following set of instructions:
I_1: $R_1 \leftarrow R_2 + R_3$
I_2: $R_3 \leftarrow R_1 + R_2$
I_3: $R_1 \leftarrow R_1 * R_3$
The time taken by the 4-stages of the pipeline is given below:

	Fetch	Decode	Execute	Write
I_1	1	2	2	1
I_2	1	2	1	2
I_3	1	1	2	1

What is the number of cycles needed to execute above instructions (use operand forwarding)?
(A) 9 (B) 10
(C) 11 (D) 12

12. Consider the execution of n instructions using k stages of a pipeline, each stage requires 't' time units. Which of the following expression provides the speed up measure of the pipeline?
(A) $\frac{nk}{n+k-1}$ (B) $\frac{nk}{n+k}t$
(C) $\frac{n}{(n+k-1)}$ (D) $\frac{k}{n+k}$

13. Consider 2 MB of RAM and 4 KB of cache with block size of 16 B. What are the sizes of fields used in associative mapping technique?
(A) 16, 5 (B) 8, 9, 4
(C) 9, 8, 4 (D) 17, 4

14. Consider a cache, which requires 2 clock cycles. If there is a cache miss, it will stall the processor for an additional 5 clock cycles. Then what will be the hit rate to achieve an average memory access of 3 clock cycles?

(A) 80% (B) 85%
(C) 90% (D) 95%

15. A digital computer has a memory unit of 64 K × 16 and a cache memory of 1 K words. The cache uses direct mapping with a block size of 4 words. The number of bits present in each line of cache are________.
(A) 20 bits (B) 22 bits
(C) 26 bits (D) 33 bits

16. Consider a cache of 4 K blocks, a 4 word block size and a 32 bit address main memory. What is the total number of tag bits per set for 4 way set associative cache?
(A) 18 (B) 36
(C) 72 (D) 64

17. A 5-stage pipeline contains IF, ID, FO (fetch operands), EX, WB stages. Each stage takes 1 clock cycle. Consider the execution of the following two instructions on this pipeline:
I_1: ADD a, b; $a \leftarrow a + b$
I_2: MUL c, a; $c \leftarrow c * a$
What is the number of clock cycles required for the execution using operand forwarding?
(A) 6 (B) 7
(C) 8 (D) 9

18. Consier a main memory address of p-bits and an associated direct-mapped cache of having 2^n blocks. Block size is 2^m bytes. Then the Tag field is of ______ bits.
(A) $p - (n + m + 2)$ (B) $p + n + m$
(C) $p - n + m$ (D) $p - n - m$

19. A 2-way set-associative cache is made up of 32-bit words, has 4 words per line and 4096 sets. Then the cache capacity in bytes is
(A) 32 K (B) 64 K
(C) 128 K (D) 256 K

20. A main memory of a computer has 4096 blocks, each consisting of 128 words. Each word is of 32-bits in size. Then the number of bits present in main memory address is _____ bits.
(A) 18 (B) 19
(C) 20 (D) 21

21. Consider a computer, whose address has M bits (using byte addressing), the cache data size is C bytes, the block size is $B = 2^b$ bytes and the cache is k-way set-associative. Then the number of bits in the set field of the address is given by
(A) $\log_2^c - \log_2^M$ (B) $\log_2^c - \log_2^M - b$
(C) $\log_2^M - b$ (D) $\log_2^B - \log_2^M$

22. Consider a 5-stage pipeline with the stage delays as shown below:

Stage	Delay
Fetch	30 ns
Decode	40 ns
Execute	35 ns
Memory	50 ns
Write	10 ns

Latch delay between the pipeline stages is 2 ns.
What are the cycle time and latency values (in ns) of an instruction respectively?
(A) 50, 50 (B) 52, 260
(C) 50,1 (D) 52, 1

23. Consider the execution of the following program on a 5 stage pipeline with the stages Fetch (F), Decode (D), Execute (E), Memory (M) and write (W).
ADD R_1, R_2, 10; $R_1 \leftarrow R_2 + 10$
LOAD R_2, 4 (R_1); $R_3 \leftarrow$ M[R_1 + 4]
ADD R_4, R_2, R_3,; $R_4 \leftarrow R_2 + R_3$
STORE R_4, 8(R_1); $M[8 + R_1] \leftarrow R_4$
LOAD R_5, 0(R_6); $R_5 \leftarrow M(R_6)$
OR R_5, R_1, R_4,; $R_5 \leftarrow R_1$ or R_4
If each stage requires one clock cycle, the number of stalls required for the program execution with forwarding are
(A) 0 (B) 1
(C) 2 (D) 3

24. The outcome of a branch is given as:
T, T, NT, T
Where T: Taken
NT: Not Taken
What is the accuracy of 'always taken' predictor for the above sequence of branch outcomes?
(A) 100% (B) 75%
(C) 50% (D) 25%

25. The outcome of a branch is given as:
T, T, NT, T.
Where T : Taken
NT: Not Taken
What is the accuracy of '2-bit predictor' for the above sequence of branch outcome?
(If the 2-bit predictor starts with T)
(A) 100% (B) 75%
(C) 50% (D) 25

Answer Keys

1. C	**2.** B	**3.** A	**4.** B	**5.** A	**6.** C	**7.** A	**8.** D	**9.** B	**10.** C
11. B	**12.** A	**13.** D	**14.** A	**15.** B	**16.** C	**17.** A	**18.** D	**19.** C	**20.** D
21. B	**22.** B	**23.** B	**24.** B	**25.** B					

Hints and Explanations

1. Random access uses a decoder to instantly access the location regardless of current state of the memory where as sequential and Direct methods depends on current data read/write position. Choice (C)

2. Choice (B)

3. Write-back scheme is faster than write-through write-back improves performance but is complex to implement. Choice (A)

4. Increasing the degree of associativity of a cache will decrease the miss rate, decreases the number of sets and increases the number of elements per set. Choice (B)

5. Choice (A)

6. With large cache memories, the hit rate is improved. Cost increases, speed reduced, power consumption is high and reliability is reduced. Choice (C)

7. If there is an increase in pipeline depth then clock frequency, CPI, mis-prediction penalty increases. Choice (A)

8. Choice (A), (B), (C) are all the necessary conditions for an n stage pipeline to be efficient.
Equal cycle time means no structural hazards. Equal number of cycles means no control hazards.
No stalls means no data hazards. Choice (D)

9. Register renaming is used to avoid WAR and WAW hazards. Choice (B)

10. Miss time = 10 ns
Hit time = 1 ns
90% are hits.
Average memory access time
= 0.9 * 1 + 0.1 * 10
= 0.9 + 1 = 1.9 ns. Choice (C)

11.

	1	2	3	4	5	6	7	8	9	10
I_1	F	D	D	E	E	W				
I_2		F			D	D	E	W	W	
I_3			F				D	E	E	W

∴ 10 clock cycles required. Choice (B)

12. Choice (A)

13. RAM size = 2 MB = 2^{21} B

21 bits	
Tag	Offset

Block size = 16 B = 2^4 B
⇒ offset = 4
⇒ Tag = 21 – 4 = 17. Choice (D)

14. Cache hit requires 2 clock cycles.
Cache miss requires 7 clock cycles.
Average memory access requires 3 clock cycles.
Let hit rate is x, then $3 = x * 2 + (1 - x)7$
⇒ $3 = 2x + 7 - 7x$
⇒ $5x = 4$
⇒ $x = \frac{4}{5} \times 100 = 80\%$ Choice (A)

15. Main memory capacity is 64 K × 16.
It has 16-bit address

16 bits		
Tag	Line	word

Block size = 4 words = 2^2
⇒ word size = 2
Number of lines in cache $= \frac{2^{10}}{2^2} = 2^8$
∴ line field width = 8
⇒ Tag = 16 – 10 = 6
Each line cache holds
Tag + Data = 6 + 16-bits = 22-bits. Choice (B)

16. Main memory address has 32-bits.

Tag	Set	Offset

Block size = 4 words = 4 × 4 Bytes = 2^4 B
⇒ offset = 4
Number of blocks in cache = 4 K = 2^{12}
Number of sets $= \frac{2^{12}}{4} = 2^{10}$
⇒ set field width = 10
∴ Tag = 32 – (10 + 4) = 18
Number of tag bits per set is 18 * 4 = 72 bits. Choice (C)

17.

	1	2	3	4	5	6	7	8	9
I_1	IF	ID	FO	EX	WB				
I_2		IF	ID	FO	EX	WB			

∴ number of clock cycles required = 6. Choice (A)

18.

p-bits		
Tag	Line	Offset
	n	m

$n\ m$
⇒ Tag = $p - (n + m)$ bits. Choice (D)

19. Number of sets = 4096
Number of words = 4 words
Word length = 32-bits = 4 B

$\Rightarrow$ Number of words (in bytes) = 4 * 4 B = 16B

The cache is 2-way set associative.

Cache capacity = 2 * 4096 * 16

$= 2^1 * 2^{12} * 2^4$

$= 2^{17}$ B = 128 KB. Choice (C)

20. Number of blocks = 4096

Number of words per block = 128

Word size = 32 bits = 4 B

Number of words per block

(in bytes) = 128 * 4 B = 512 B

Main memory capacity = 4096 * 512 B

$= 2^{12} * 2^9\text{B} = 2^{21}$ B

$\therefore$ 21-bits required for main memory address.

Choice (D)

21. Cache size = C bytes

Block size, $B = 2^b$ bytes

The cache is m-way set-associative.

Number of sets in cache $= \dfrac{C}{M \times B}$

Bits required for set field is $\log_2^{\left(\frac{C}{M}\times 3\right)}$

$= \log_2^C - \log_2^{(M\times B)} = \log_2^C - \log_2^M - \log_2^B$

$= \log_2^C - \log_2^M - \log_2^{2^b}$

$= \log C - \log M - b$. Choice (B)

22. Cycle time = maximum stage delay + latch delay

= 50 + 2 = 52 ns

Latency = number of stages * cycle time

= 5 * 52 = 260 ns. Choice (B)

23.

	1	2	3	4	5	6	7	8	9	10	11
I_1	F	D	E	M	W						
I_2		F	D	E	M	W					
I_3			F		D	E	M	W			
I_4				F		D	E	M	W		
I_5					F		D	E	M	W	
I_6						F		D	E	M	W

One stall caused by 2^{nd} and 3^{rd} instructions.

Choice (B)

24. Given predictor always predicts about the branch 'Taken'.

Prediction	T	T	T	T
Outcome	T	T	NT	T
Result	True	True	False	True

1 out of 4 predictions is wrong.

i.e., Accuracy of predictor $= \dfrac{3}{4}$

* 100 = 75%. Choice (B)

25. Using 2-bit predictor, the predictor will change its decision with two successive wrong predictions.

Initial prediction: T

Prediction	T	T	T	T
Outcome	T	T	NT	T
Result	True	True	False	True

Accuracy $= \dfrac{3}{4}$

* 100 = 75%. Choice (B)

Computer Organization and Architecture Test 3

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. A computer 'A' uses the following 32-bit floating point representation of real numbers.

S	Mantissa	Exponent
31	30 … 8	7 … 0

Computer 'B' uses the following floating point representation scheme.

S	Mantissa	Exponent
31	30 … 7	6 … 0

Which of the following statement is TRUE with regard to computer B's method of representing floating-point numbers over computer A's method?

(A) Both range and precision are decreased.
(B) The range is decreased but the precision is increased.
(C) The range is increased but the precision is decreased.
(D) Both range and precision remain same.

2. The minimum number of control bits required to execute a microprogram which has 50 control signals is ________.

(A) 5 (B) 6
(C) 50 (D) 100

3. Consider the following instructions:
BEQ R_0, R_1, L_1
The opcode is BEQ, which means Branch if Equal. The instruction checks the equality of R_0, R_1 and if both are equal jump to L_1. Which of the following correctly specifies given instruction but with much greater branching distance?

(A) compare R_0, R_1 if zero jump to L_1
(B) LOAD R_0 Branch if equal R_1, L_1
(C) Branch if not equal R_0, R_1, L_2 Jump L_1 L_2:
(D) Branch if not Equal R_0, R_1, L_1 Jump L_2 L_1:

4. Consider a loop branch that branches 100 times in a row, then it is not taken once. Assume that the prediction bit for this branch remains in the prediction buffer. The prediction accuracy for this branch by using 1-bit branch history table prediction scheme (in percentage) is ________.

(A) 90 (B) 95
(C) 98 (D) 99

5. The biased exponent value for double precision floating point numbers is _________.

(A) 1023 (B) 1024
(C) 256 (D) 255

6. Consider the following instruction:
ADD R_1, (R_2, R_3)
Here R_1, R_2, R_3 are registers
The Sum of data present in the R_2 and R_3 is stored in a 32-bit register R_1.
Which of the following mode best reflects the mode of second operand?

(A) Indexed mode
(B) Base Register mode
(C) Base with index mode
(D) Base with index and offset mode

7. Consider an instruction format with fields containing zeros:

0000	0000 0000	0000 0000	0000 0000 0000
Opcode	Destination Register	Source Register	Immediate value

What is the maximum possible number of operations, registers with the given instruction format?

(A) 4, 8 (B) 4, 16
(C) 16, 256 (D) 16, 65536

8. A 64 M-bit DRAM organized as 4 M addresses of 16-bit words each. A memory system is built using 128 M addresses of 256-bit words each. How many DRAM chips that are required for this memory system?

(A) 16 (B) 32
(C) 128 (D) 512

9. Consider a hypothetical 64-bit micro-processor having 64-bit instructions composed of two fields: Opcode: 2-bytes. Immediate operand or an operand address: remaining bytes.
What is the maximum directly addressable memory capacity (in bytes)?

(A) 2^{16} (B) 2^{48}
(C) 2^{64} (D) 2^{24}

10. Consider a machine with a byte addressable main memory of 4 GB and a block size of 16 bytes. Assume that a direct mapped cache consisting of 32 lines is used with this machine. How many bytes of main memory can be stored in the cache?

(A) 4096 (B) 2^{20}
(C) 512 (D) 736

11. Consider a dynamic RAM that must be given a refresh cycle 64 times per ms. Each refresh operation requires 150 ns; a memory cycle requires 250 ns. What percentage of the memory's total operating time is given to refreshes?

(A) 1% (B) 3%
(C) 5% (D) 10%

12. A DMA module is transferring characters to memory using cycle stealing, from a device transmitting at

9600 bps. The processor is fetching instructions at the rate of 1 million instructions per second (1 MIPS). By how much the processor is slowed down due to the DMA activity?

(A) 0.0012% (B) 0.01%
(C) 0.001% (D) 0.12%

13. Match list-A with list-B and select the correct answer using the code given below the list:

	List–A		List–B
a.	Cache	1.	Printer
b.	DMA I/O	2.	Disk
c.	Interrupt I/O	3.	High speed RAM

(A) a–1, b–2, c–3 (B) a–2, b–3, c–1
(C) a–3, b–2, c–1 (D) a–3, b–1, c–2

14. The speed gained by a 'p' segment pipeline executing 'q' tasks is:

(A) $\dfrac{(q+p-1)}{pq}$ (B) $\dfrac{p+q}{pq-1}$

(C) $\dfrac{pq}{p+q-1}$ (D) $\dfrac{p+q}{pq+1}$

15. The IEEE 32-bit floating point format of –6 is:

(A) 1 10000001 10000000000000000000000
(B) 1 00000010 00000000000000000000000
(C) 1 00000001 10000000000000000000000
(D) 1 10000001 00000000000000000000000

16. Consider below code segment:

LOAD R_1, M[1000]
LOAD R_2, M[1002]
ADD R_3, R_1, R_2
STORE R_3, M[1008]
LOAD R_4, M[1004]
ADD R_5, R_1, R_4
STORE R_5, M[1010]

Assume that this program is executed on a pipelined processor with 5 stages: FI (Fetch Instruction), RD(Read registers while Decoding), EX (Execute the operation or calculate the address), MEM (Access an operand in data memory), WR (write result into a register).

The first operand of each instruction will be the destination. What is the minimum number of stalls that will be there in the reordered code of given code if the processor uses forwarding also?

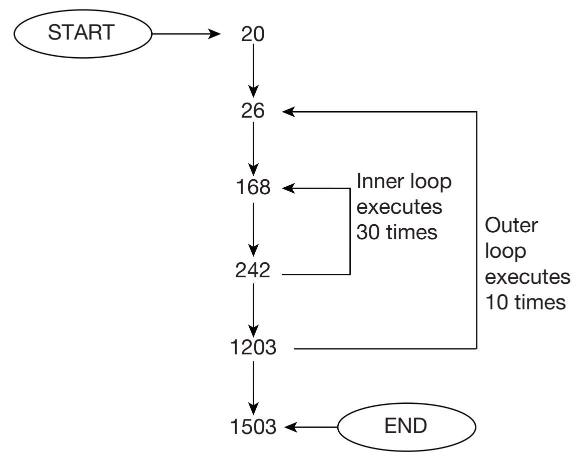
(A) 0 (B) 1
(C) 2 (D) 3

17. Consider a 2 × 8 two-dimensional array of elements, M. Assume that each element in the array occupies one word and the array elements are stored in column-major order in the main memory from location 2000 to location 2015. The cache consists of 8 blocks and each block will have just two words. Assume also that whenever needed, LRU replacement policy can be used. What is the percentage of cache utilization for Direct mapped, Associative and 2-way set-Associative respectively, if the processor accesses the following elements?

$M_{0,0}$, $M_{0,1}$, $M_{0,2}$, $M_{0,3}$, $M_{0,4}$, $M_{0,5}$, $M_{0,6}$, $M_{0,7}$, $M_{1,0}$, $M_{1,1}$, $M_{1,2}$, $M_{1,3}$, $M_{1,4}$, $M_{1,5}$, $M_{1,6}$, $M_{1,7}$.

(A) 50%, 100%, 50% (B) 50%, 50%, 50%
(C) 100%, 100%, 100% (D) 100%, 100%, 50%

18. Consider the given program structure, which is in Main memory:



The memory addresses are in decimal. The program consists of two loops along with start and end statements. All the instructions in the program are executed in sequential manner. The program is to be run on a computer that has an instruction cache of size 1 K words organized in a direct-mapped manner. The main memory size is 64 K words with block size of 128 words. Let the cycle time of main memory is 10 ns and cycle time of the cache is 1 ns.

Then the total time needed for reading instructions from main memory to the cache during the execution of the program (in nano seconds) is ________.

(A) 1280 (B) 4864
(C) 48640 (D) 61440

19. A pipelined processor has two branch delay slots, An optimizing compiler can fill one of these slots 75% of the time and can fill the second slot only 20% of the time. What is the ratio of improvement in performance achieved by this optimization to without optimization, assuming that 10% of the instructions executed are branch instructions?

(A) 1.102 (B) 1.086
(C) 0.9 (D) 1.105

20. Consider a system with a 4 KB, 4-way set associative cache memory with 128 lines, a 1024 word array where each element is a 32-bit word. When a program accesses this array with a scale of D, it means starting with the first element, the program accesses every

D^{th} element. For example, for $D = 1$, the program accesses every element, for $D = 2$, the program accesses every second element and so on. Assuming a cache that is initially empty and a program makes one pass over this array with a scale of D, what is the miss rate generated for $D = 8$?

(A) $\frac{1}{2}$ (B) $\frac{1}{4}$
(C) $\frac{1}{8}$ (D) $\frac{1}{16}$

21. A computer has 32-bit instructions and 12-bit addresses. If there are 240 two-address instructions, how many one-address operations can be formulated?
(A) 4096 (B) 65536
(C) 8192 (D) 131072

22. Consider a pipelined processor with a 5-stage pipeline. Assume that all instructions take 5 cycles. The dynamic instruction count by type, as a percentage of the total, is as follows:
10% store instructions
20% load instructions
30% branch instructions
40% ALU instructions
What is the ideal speed-up due to pipelining for this processor?
(A) 2.5 (B) 5
(C) 10 (D) 50

23. For the data given in Q. No. 22, let stalls due to data hazards occur only under two reasons.
A stall of two cycles occur when a load instruction is followed by an ALU instruction that uses the result of load. This scenario exists for 40% of the load instructions.
A stall of three cycles occur when a branch instruction is preceded by an ALU operation whose result is used as a branch condition. This scenario exists for 50% of the branch instructions. What is the decrease in the ideal speed up of pipelining only due to data hazards?
(A) 50% (B) 75.6%
(C) 18.9% (D) 37.8%

24. Given
$x = (0100\ 0110\ 1101\ 1000\ 0000\ 0000\ 0000\ 0000)_2$ and
$y = (1011\ 1110\ 1110\ 0000\ 0000\ 0000\ 0000\ 0000)_2$,
representing single precision IEEE 754 floating point numbers. Then the respective values of $x + y$ and $x * y$ in decimal (approximately) are:
(A) 27647.5625 and –12096
(B) 27647.5625 and –24192
(C) 13823.75 and 24192
(D) 13823.75 and –24192

25. A 5-stage pipeline has the following stages:
IF: Instruction fetch
ID: Instruction decode and register file read
EX: Execution or address calculation
MEM: Data memory access
WB: Write back
The following code executed on this pipeline:

Instruction	Operation
ADD R_1, R_2, R_3	$R_1 \leftarrow R_2 + R_3$
SUB R_4, R_1, R_5	$R_4 \leftarrow R_1 - R_5$
LOAD R_6, 200(R_1)	$R_6 \leftarrow M[200 + R_1]$
ADD R_7, R_1, R_6	$R_7 \leftarrow R_1 + R_6$

Use forwarding to resolve data hazards. Then the number of stalls that will occur because of data hazards in given code is ______.
(A) 0 (B) 1
(C) 2 (D) 3

26. Consider a floating point representation: $c.r^e$ where c represents coefficient register of size 10 in which MSB bit is used to represent sign, r represents radix and e represents contents of exponent register of size 5, in which MSB is used to represent sign. Then the contents of coefficient and exponent registers for the number +1001.110 will be:
(A) 0100111000, 00100 (B) 0001001110, 00100
(C) 1001110000, 10100 (D) 1001110000, 10101

27. Consider a 32-bit microprocessor, with a 16-bit external data bus, driven by an 8 MHz input clock. Assume that this microprocessor has a bus cycle whose minimum duration equals four input clock cycles. What is the minimum data transfer rate across the bus that this microprocessor can sustain, in bytes?
(A) 2 MB/sec (B) 4 MB/sec
(C) 6 MB/sec (D) 8 MB/sec

28. Consider a bus structure in which a single internal bus connects the ALU and all processor registers.
Which of the following represents the correct sequence of micro-operations to add a number to the accumulator when the number is an indirect address operand?
(A) t_1: MAR ← (IR(address))
t_2: MBR ← memory
t_3: Y ← (MBR)
t_4: $Z \leftarrow (AC) + (Y)$
t_5: $AC \leftarrow (Z)$
(B) t_1: MAR ← (IR(address))
t_2: MBR ← memory
t_3: $Z \leftarrow (AC)$ + (MBR)
t_4: $AC \leftarrow (Z)$
(C) t_1: MBR ← (IR(address))
t_2: $Z \leftarrow (AC)$ + (MBR)
t_3: $AC \leftarrow (Z)$
(D) t_1: MAR ← (IR(address))
t_2: MBR ← memory
t_3: MAR ← (MBR)
t_4: MBR ← memory

t_5: $Y \leftarrow (MBR)$
t_6: $AC \leftarrow (AC) + (Y)$
t_7: $AC \leftarrow (Z)$

29. For the data given in Q. No. 28, what is the number of clock cycles required for above operation if each micro-operation takes one clock cycle?
(A) 5 (B) 4
(C) 3 (D) 7

30. The access time of a cache memory is 100 ns and that of main memory is 1 μs. 80% of the memory requests are for read and others are for write. Hit ratio for read only accesses is 0.9. A write-through procedure is used. The average access time of the system for both read and write requests is:
(A) 160 ns (B) 200 ns
(C) 360 ns (D) 720 ns

31. Consider a new instruction named branch-on-bit-set. The instruction
"bbs reg, pos, label"
jumps to label if bit in position 'pos' of register operand 'reg' is one. A register is 32 bits wide and the bits are numbered 0 to 31, bit in position 0 being the least significant. Consider the following emulation of this instruction on a processor that does not have branch-on-bit-set implemented.
result ← reg & mark
Branch to label if result is non-zero.
The variable 'result' is temporary register. For correct emulation the variable mask must be generated by:
(A) mask ← 0*xf* (B) mask ← *pos*
(C) mask ← 0*xffff* >> *pos* (D) mask ← 0*x*1<< *pos*

32. Consider a computer with the following characteristics: Total main memory: 1 MB; word size is 1 byte; Block size of 16 bytes; and cache size of 64 kbytes; for the main memory address *F*0010, what will be the cache line bits for a direct mapped cache?
(A) 1111 (B) 0000
(C) 0000 0000 0001 (D) 000000001000

33. Consider a system in which a data transfer over a bus takes 500 ns. Transfer of bus control in either direction, from processor to I/O device or vice versa, takes 250 ns. One of the I/O devices has a data transfer rate of 50 kb/s and employs DMA. Data is transferred one byte at a time. Suppose we employ DMA in a cycle-stealing mode. When transferring a block of 128 bytes, it would tie up the bus for (in micro seconds) ________.
(A) 250 (B) 0.2
(C) 128 (D) 0.4

34. A PC relative mode branch instruction is 2 bytes long. The address of the instruction, in decimal, is 356029. Determine the branch target address if the signed displacement in the instruction is –31.
(A) 356029 (B) 356030
(C) 356031 (D) 356000

35. Consider a system employing interrupt driven I/O for a particular device that transfers data on an average of 10 KB/sec on a continuous basis. Assume that interrupt processing takes 100 μs (i.e., the time to jump to the ISR, execute it and return to the main program). Determine what fraction of processor time is consumed by this I/O device if it interrupts for every byte.
(A) 1 (B) 10
(C) 100 (D) 0.8

Answer Keys

Hints and Explanations

1. The range of a floating point number depends on exponent size. As exponent size in '*B*' decreases, the range also decreases.
The precision specifies number of digits after decimal point, which increases in '*B*' computer. Choice (B)

2. Using Vertical Microprogramming, there will be 6-control bits to provide 50 control signals.
($\because 2^6 = 64 > 50$) Choice (B)

3. Given instruction BEQ R_0, R_1, L_1.
This instruction can be replaced by following instructions, to achieve greater branching distance:
BNE R_0, R_1, L_2
Jump L_1, L_2:
We get much greater branching distance by using 1-address instruction: Jump L_1.
We can't use zero-address as we need to specify the opcode 'jump'
By using the instruction 'Jump L_1' the address space is more so we can specify much greater branching distance. Choice (C)

4. Branch history table is a small memory, which contains a bit that says whether the branch was recently taken or not.

In the given problem, the loop executes 100 times but in the 101^{th} time the loop is not taken.
But it will be incorrectly predicted by 1-bit branch history table prediction as the loop is taken for 100 times. In the 1^{st} iteration also the predictor specifies incorrect branch prediction as the bit is set to 'not taken' in the exit stage of last execution of the program.

$\therefore$ 2 wrong predictions, out of 101 predictions.

$\therefore$ Prediction Accuracy percentage

$= \frac{99}{101} \times 100 = 98\%$ Choice (C)

5. In Double precision floating point format,
Number of bits for exponent = 11

$\therefore$ Biased exponent $= 2^{k-1} - 1$,
Where k is the number of bits used for exponent.
Here $k = 11$, hence Biased exponent
$= 2^{10} - 1 = 1023$. Choice (A)

6. If we assume R_2 as Base register, R_3 as Index register, then the mode will be Base with index mode.
Choice (C)

7. Number of bits in opcode = 4

$\Rightarrow$ Number of operations possible $= 2^4 = 16$
Number of bits in src/dest. Registers = 8

$\therefore$ Number of registers $= 2^8 = 256$ Choice (C)

8. Each DRAM has $4M$ addresses of 16-bit words.

$\Rightarrow$ DRAM capacity $= 4M \times 16$
Memory system capacity $= 128M \times 256$

$\therefore$ Number of chips required $= \frac{128M \times 256}{4M \times 16} = 512$
Choice (D)

9. Instruction size = 64-bits
Opcode size = $2B$ = 16-bits
Operand/Address field = 64 – 16 = 48-bits.
The 48-bits can be used to specify a particular address.
$\therefore$ Maximum directly addressable memory $= 2^{48}$
Choice (B)

10. Number of lines in cache = 32
There are 32 lines in cache. Each line will have 16 bytes.
$\therefore$ Total bytes of memory in cache
$= 16 \times 32 = 512$ bytes Choice (C)

11. The DRAM has given a refresh cycle 64 times per ms.
Time required for one refresh operation = 150 ns
In 1 ms, the time required to refresh is 64×150 ns = 9600 ns

$\therefore$ The fraction of time devoted to memory refresh is
$\frac{9600 \times 10^{-9}}{10^{-3}} = 0.0096$

$\therefore$ Approximate percentage of the memory's total operating time given to refreshes is 1%.
Choice (A)

12. The DMA is transmitting at a rate of 9600 bits per second i.e., it is transmitting $\frac{9600}{8} = 1200$ characters per second. The processor is processing at a rate of 1 million instructions per second i.e., It will take $\frac{1}{10^6} = 1\mu$ second to process a single instruction.
A single character will be processed by DMA in
$\frac{1}{1200} \approx 833\ \mu s$

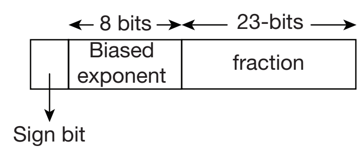
$\therefore$ Slow down of processor due to DMA
$= \frac{1}{833} \times 100 = 0.12\%$ Choice (D)

13. Cache is high speed RAM, DMA I/O is used with disk, Interrupt I/O is used with printer. Choice (C)

14. Without pipelining, execution time $= pq$
with pipelining, execution time $= p + q - 1$

$\therefore$ speed up $= \frac{pq}{p+q-1}$ Choice (C)

15. IEEE 32-bit floating point representation will be in the form of:



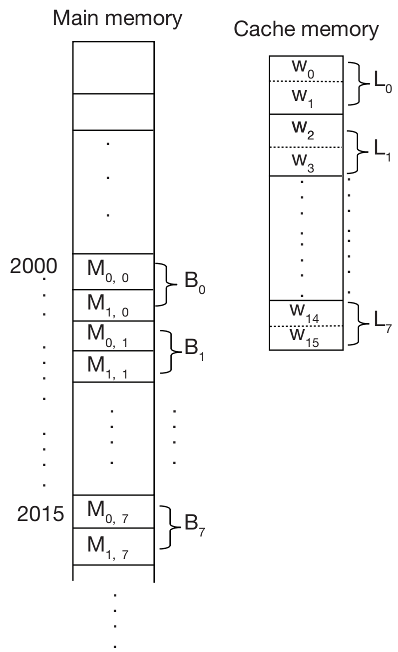
6 = 110
For –6 sign bit is 1.
$6 = 110 = 1.10 \times 2^{010}$
Exponent = 010
Biased exponent = 127 + 2 = 129 = 10000001
Fraction = 10000000000000000000000
Hence IEEE 32-bit floating point representation of –6 is:
110000001
10000000000000000000000 Choice (A)

16. In given code stalls occur before the ADD instructions. 2 stalls are there in given code. To minimize stalls, we reorder the code. In the reordered code place LOAD R_4, $M[1004]$ before ADD R_3, R_1, R_2.
The resultant code will be:

LOAD R_1, $M[1000]$
LOAD R_2, $M[1002]$
LOAD R_4, $M[1004]$
ADD R_3, R_1, R_2
ADD R_5, R_1, R_4
STORE R_3, $M[1008]$
STORE R_5, $M[1010]$

No stalls in the reordered code. Choice (A)

17. The Array $M_{2\times 8}$ is stored in column-major order in the main memory, i.e.,



In direct mapping, B_0 is placed in L_0, B_1 in L_1, B_2 in L_2, ..., B_7 in L_7 to access the elements $M_{0,0} - M_{0,7}$
The remaining elements are already in cache. All those accesses will be hits.
As all the 8-blocks used, cache utilization is 100%.
In Associative mapping, each block of main memory will be placed at anywhere in the cache lines. Also 8-accesses will be misses and the remaining will be hits. No need of replacement and all lines of cache will be used.

∴ Cache utilization = 100%
In 2-way set-Associative mapping, two blocks will be treated as a single set. There will be 4-sets.

Cache memory

L_0L_1	Set 0
L_2L_3	Set 1
L_4L_5	Set 2
L_6L_7	Set 3

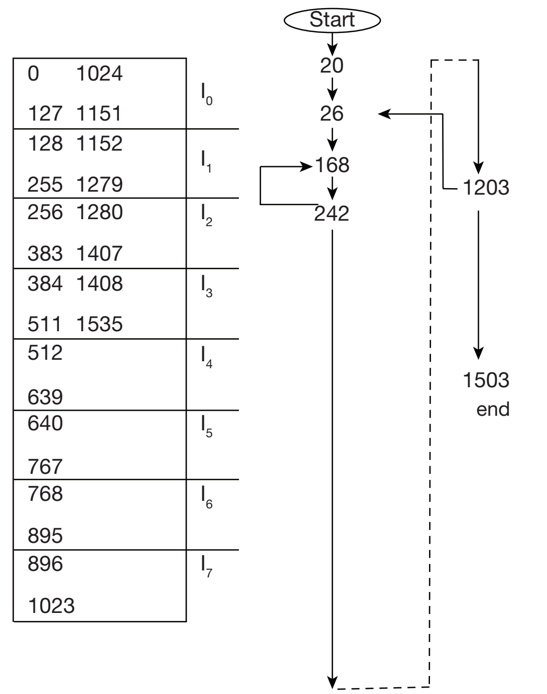
All the four sets are used. Set 0 consists B_0, B_4, set 1 contains B_1, B_5. Like this all sets are used. Hence cache utilization is 100%. Choice (C)

18. Given main memory size = 64 K = 2^{16} words
Block size = 128 = 2^7 words
Cache size = 1 K = 2^{10} words
Word field size = 7

$$\text{Number of lines} = \frac{2^{10}}{2^7} = 2^3$$

∴ Line field size = 3
⇒ Tag = 16 – (7 + 3) = 6

The cache memory is shown below with main memory block addresses.



Hence the sequence of reads from the main memory blocks into cache line is:

$$\text{Line: } \underbrace{0, 1, 2, 3, 4, 5, 6, 7, 0, 1,}_{\text{Pass 1 outer loop}} \underbrace{0, 1, 0, 1,}_{\text{Pass 2}} \ldots \underbrace{0, 1, 0, 1, 2, 3}_{\text{Pass 10}}$$

i.e., in pass1 of outer loop the lines 0, 1, 2, 3, 4, 5, 6, 7, 0, 1 will be accessed. In pass 2 0, 1 are accessed for (0 – 127), (128 – 255) and again 0, 1 are accessed for (1024 – 1151), (1152 – 1279).
In last pass 0, 1, 0, 1, 2, 3 lines will be accessed.

∴ Total time for reading the blocks of main memory into the cache
= (10 + 9 × 4 + 2) × 128 × 10
= 61440 n sec. Choice (D)

19. Let the number of instruction be 100.
Without optimization, time required to execute 100 Instructions = 100 + 10 × 2 = 100 + 20 = 120
With optimization time required
= (120 – 0.75 ×10 – 0.20 × 10) = 110.5
∴ Improvement using optimization

$$= \frac{120}{110.5} = 1.086.$$ Choice (B)

20. Number of lines in cache = 128
As the cache is a 4-way set associative, each set contains 4-blocks.

$$\therefore \quad \text{Number of sets} = \frac{128}{4} = 32$$

So there will be 32 misses.

But the program accesses every 8th word.

$\therefore$ Number of misses $= \frac{32}{8} = 4$

Hence miss rate $= \frac{1}{4}$ Choice (B)

21. Instruction size = 32-bits
Two address instruction format will be

opcode	address1	address2
8	12	12

There will be 2^8 possible combinations of operations.
Two address instructions = 240
Operations for single address instructions
= 256 – 240 = 16
Single address instruction format will be

opcode	address
	12 bits

Total one address operations = $16 \times 2^{12} = 65536$.
Choice (B)

22. The ideal speed up of a pipelined processor is equal to the number of stages in the pipeline.
$\therefore$ As there are 5-stages the speed will be 5.
Choice (B)

23. Ideal speed up = 5
Speed up due to Data hazards

$$= \frac{\text{Pipeline Depth}}{1 + (\text{load frequency} \times \text{load penalty}) + (\text{branch frequency} \times \text{branch penalty})}$$

$$= \frac{5}{1 + (0.2 \times 0.4 \times 2) + (0.3 \times 0.5 \times 3)}$$

$$= \frac{5}{1 + 0.16 + 0.45} = 3.11$$

$\therefore$ Speed up $= \frac{5 - 3.11}{5} \times 100 = 37.8\%$ Choice (D)

24. Given x = 0100 0110 1101 1000 0000 0000 0000 0000
y = 1011 1110 1110 0000 0000 0000 0000 0000
IEEE 754 floating point representation numbers has the following format:

Sign	Biased exponent	Mantissa
1	8	23

For x, sign bit = 0 $\Rightarrow$ sign = +
Biased exponent = 100 01101 = 141
Exponent = 141 – 127 (Bias) = 14
Mantissa = 1.101 1000 0000 0000 0000 0000
$\therefore$ x = +1.101 1000 0000 0000 0000 0000 $\times 2^{14}$
= +27648
For y, sign bit =1 $\Rightarrow$ sign = –
Biased exponent = 011 1110 1 = 125
Exponent = 125 – 127 = –2
Mantissa =1.110 0000 0000 0000 0000 0000
$\therefore$ y = –1.110 0000 0000 0000 0000 0000 $\times 2^{-2}$
= –0.4375
$x + y$ = 27648 – 0.4375 = 27647.5625
$x * y$ = 27648 * 0.4375 = –12096 Choice (A)

25. Given code:
I_1: ADD R_1, R_2, R_3
I_2: SUB R_4, R_1, R_5
I_3: LOAD R_6, 200(R_1)
I_4: ADD R_7, R_1, R_6
I_2, I_3, I_4 are dependent on I_1. I_4 dependent on I_3.
The execution chart is shown below:

	1	2	3	4	5	6	7	8	9	10
I_1	IF	ID	EX	MEM	WB					
I_2		IF	ID	EX	MEM	WB				
I_3			IF	ID	EX	MEM	WB			
I_4				IF	Stall	ID	EX	MEM	WB	

$\therefore$ R_1 can be forwarded to I_2, I_3 and I_4, but R_6 (in I_3) cannot be forwarded to I_4 immediately, so one stall occurs. Choice (B)

26. Given number +1001.110

Then c =

0	1	0	0	1	1	1	0	0	0

$\underbrace{0}_{\text{sign}}\ \underbrace{1\,0\,0\,1\,1\,1\,0\,0\,0}_{\text{fraction}}$

e =

0	0	1	0	0

$\underbrace{0}_{\text{sign}}\ \underbrace{0\,1\,0\,0}_{\text{exponent}}$

The decimal point will be at 4th position from left.
Choice (A)

27. Input clock frequency = 8 MHz

clock cycle $= \frac{1}{8 \text{ MHz}} = 125$ ns

Given that bus cycle = 4 × clock cycle
= 4 × 125 = 500 ns
Data bus width = 16-bits = 2 B
$\therefore$ 2 B can be transferred for every 500 ns.

$\therefore$ Transfer rate $= \frac{2 \text{ B}}{500 \text{ ns}} = 4$ MB/sec Choice (B)

28. As the number is an indirect address operand, the effective address will present in the given address location. So we refer two times to get the actual operand from memory. Hence the correct sequence of micro-operation is Choice (D)

29. As there are 7 micro-operations and each micro-operation takes one clock cycle, the total number of clock cycles for addition with an indirect address operand = 7.
Choice (D)

30. Access time of cache = 100 ns
Access time of main memory = 1 μs = 10^3 ns

Read requests = 80%
Write requests = 20%
Hit ratio for read only access = 0.9
Write-through means main memory is updated while updating cache memory.
Average access time of the system
$= 0.8(0.9 \times 100 + 0.1(100 + 1000)) + 0.2 \times 1000$
$= 160 + 200 = 360$ ns Choice (C)

31. The instruction "bbs reg, pos, label" jumps to label it bit in position 'pos' of register operand 'reg' is one.
To implement this instruction as
result ← reg & mask
We are performing 'and' operation between 'reg' and 'mask'.
The mask must be '1' to check a position value of 'reg'. And it is left shifted POS number of times to align that 1 to the required position of reg.
For example,
Reg = A091 = 1010 0000 1001 0001
POS = 2
Using bbs, we won't jump to label as 2^{nd} bit is zero using mask ← ox1 << POS
← ox1 << 2
← ox 0100
Now we perform AND between reg and mask. As the result is zero we won't jump to label. Choice (D)

32. Main memory = 1 MB = 2^{20} B
Word size = 1 B
Block size = 16 B = 2^4 B
Cache size = 64 KB = 2^{16} B
For Direct mapped cache:

$$\underbrace{\boxed{\text{tag}}\boxed{\text{line}}\boxed{\text{word}}}_{20}$$

word size = 4

Number of blocks in cache $= \dfrac{2^{16}}{2^4} = 2^{12}$

∴ Line = 12
tag + line = 20 – 4 = 16
Tag = 16 – 12 = 4
Given address F0010:

$$F0010 = \underset{\text{tag}}{\underline{1111}}\ \underset{\text{line}}{\underline{000000000001}}\ \underset{\text{word}}{\underline{000}}$$

∴ Line address = 0000 0000 0001 Choice (C)

33. The time required to transfer one byte is:
= 250 + 500 + 250
= 1000 ns = 1 μs.
To transfer 128 bytes, we require 128 μs.
Choice (D)

34. Instructions size = 2 B
Current instructions address = 356029
PC always points to the address of the next instruction.
i.e., 356029 + 2 = 356031
In PC-relative addressing mode, the content of PC is added to the displacement, which is given as –31.
So the branch target address
= 356031 – 31 = 356000 Choice (D)

35. Data transferred = 10 kB/sec
= 10000 Bytes/sec
Given that interrupts are generated for every 1 Byte.
There will be 10000 interrupts and rate of interrupts

$= \dfrac{1}{10000} = 100$ μs

∴ Fraction of processor time consumed by this I/O

$= \dfrac{100}{100} = 1$ Choice (A)

Computer Organization and Architecture Test 4

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. The primary memory of a computer consists of M locations, and the computer has a 4-way set associative cache consisting of 'C' locations. On an average, how many different locations in primary memory map to a particular location in the cache?

(A) 4 (B) $\frac{M}{C}$

(C) $\frac{4M}{C}$ (D) M

2. Which of the following statement is FALSE?

(A) The Program Counter and Stack Pointer are updated when a procedure call is executed on a processor.

(B) When a Procedure call is executed on a processor, data cache is flushed to avoid aliasing problems.

(C) A direct mapped cache can have a higher miss-rate than an associative mapped cache, each are of same size (i.e., same number of blocks).

(D) Programs with high temporal locality have a low cache miss rate penalty because, exactly the same addresses are re-referenced.

3. Let multiplicand be 23, multiplier be 29 and each number is represented using 6-bits. Then the difference between the total number of add/subtract operations required using unsigned binary multiplication and booths algorithm will be ________.

(A) 0 (B) 1

(C) 2 (D) 3

4. Consider a cache with a line size of 16 bytes and a main memory that requires 20 ns to transfer a 4-byte word. For any line that is written at least once before being swapped out of the cache, what is the average number of times that the line must be written before being swapped out for a write-back cache to be more efficient than a write through cache?

(A) more than 2 times (B) more than 3 times

(C) more than 4 times (D) more than 8 times

5. A certain pipelined RISC machine has 8 general purpose registers R_0, R_1, ..., R_7 and supports the following operations:

ADD $RS1$, $RS2$, Rd (Adds $RS1$ and $RS2$ and put the sum in Rd.)

MUL $RS1$, $RS2$, Rd (Multiply $RS1$ by $RS2$ and put the product in Rd.)

An operation normally takes one cycle; however, an operation takes two cycles if it produces a result required by the immediately following operation in an operation sequence. Consider the expression $xy + xz + xyz$, where variables x, y, z are located in registers R_0, R_1, R_2. The contents of these registers must not be modified, then the minimum number of clock cycles required for an operation sequence that compute the value of $xy + xz + xyz$ is ______.

(A) 5 (B) 6

(C) 7 (D) 8

6. Consider two processors, 5-stage pipeline P_5 and 7-stage pipeline P_7 to implement the same instruction set. Processor P_5 has a clock cycle of 20 ns and P_7 has a clock cycle of 17.5 ns. Which of the following is/are TRUE?

I. P_7 pipeline has better maximum throughput than P_5's pipeline.

II. The latency of a single instruction is shorter on P_7's pipeline than on P_5's pipeline.

III. Programs executing on P_7 will always run faster than the programs executing on P_5.

(A) I only (B) II only

(C) I and III only (D) II and III only

7. What is the size of the cache memory required for a direct-mapped cache with 16 KB of data and 16 B blocks, assuming a 32-bit address of main memory?

(A) 145 K bits

(B) 146 K bits

(C) 147 K bits

(D) 148 K bits

8. In a computer the exponents of a floating point number are represented as 'excess-64' integers. Two such exponents are input to a conventional 7-bit parallel adder. Which of the following should be accomplished in order to obtain a sum that is also in excess-64 notation?

(A) An end-around carry should be added to LSB.

(B) The adder outputs should be computed bitwise.

(C) The most significant adder output bit should be complemented.

(D) The adder outputs should be left unchanged.

9. The format of a double operand instruction of a CPU is shown below:

opcode	src data	dest data
← 6-bits →	← 4-bits →	← 4-bits →

20 double-operand instructions and 40 single-operand instructions must be implemented and the opcode field must identify 3-groups of n-operand instructions. The total number of zero-operand instructions that can be implemented is ______.

(A) 704 (B) 11264

(C) 16384 (D) 10496

10. A CPU has 32-bit memory address and a 256KB cache memory. The cache is organized as a 4-way set-associative cache with a cache block size of 4 words (32-bits per word). The smallest addressable unit is a byte. Then the percentage of cache memory used for tag bits is _________.

(A) 11.11 (B) 12
(C) 80.8 (D) 88.89

11. Assume that we have three significant decimal digits. What is the sum of 3.67 and 3.45×10^2 using guard and round digits and the sum of the two numbers without using guard and round digits respectively?

(A) 348, 349 (B) 349, 348
(C) 350, 347 (D) 348, 348

12. If an encoded micro-instruction format is used, then how a 10-bit micro-operation field can be divided into subfields to specify 41 different actions efficiently?

(A) 5, 5 (B) 2, 4, 4
(C) 5, 3, 2 (D) 5, 4, 1

13. The two-stages of a pipelined processor are Bus Interface Unit (BIU) and Execution Unit (EU). The BIU fetches instructions from a 4-byte instruction queue. It also calculates address, fetches operands and writes results on to memory as requested by EU. If no such requests are outstanding and the bus is free, the BIU fills vacancies (if any) in the instruction queue. When the EU completes execution of an instruction, it passes results to BIU and proceeds to the next instruction. Let the tasks performed by the BIU and EU take about equal time. The factor by which pipelining improves the performance of the processor (Ignore the effect of branch Instructions) is _________.

(A) 2 (B) 4
(C) 5 (D) 8

14. Consider a processor that includes a base with indexed addressing mode. Suppose an instruction is encountered that employs this addressing mode and specifies a displacement of 2970, in decimal. Currently the base and index register contain the decimal numbers 58022 and 8 respectively. Then the address of operand would be _________.

(A) 58022 (B) 60992
(C) 61000 (D) 2978

15. Consider a RAID level 5 organization comprising of five disks, with the parity for sets of four blocks on four disks stored on the fifth disk. The number of blocks that are accessed to write one block of data is _________.

(A) 3 (B) 4
(C) 5 (D) 6

16. Consider a static two-issue pipeline for MIPS. The two issue packets are, one ALU/branch instruction, one load/store instruction. Which of the following is the correct re-ordering of the below loop to avoid as many pipeline stalls as possible? Assume branches are predicted, so that control hazards are handled by the hardware.

loop: Load R_0, $M[100]$;	$R_0 \leftarrow M[100]$
ADD R_0, R_0, 5;	$R_0 \leftarrow R_0 + 5$
Store R_0, $M[100]$;	$M[100] \leftarrow R_0$
ADD R_1, R_1, –4;	$R_1 \leftarrow R_1 - 4$
BNE R_1, 0, loop;	branch if $R_1 \neq 0$

(A) loop: Load R_0, $M[100]$
ADD R_1, R_1, –4
ADD R_0, R_0, 5
BNE R_1, 0, loop; Store R_0, $M[100]$
(Both in single cycle).

(B) loop: Load R_0, $M[100]$
ADD R_1, R_1, –4
BNE R_1, 0, loop; ADD R_0, R_0, 5
(Both in single cycle)
Store R_0, $M[100]$

(C) Loop: Load R_0, $M[100]$
ADD R_0, R_0, 5
ADD R_1, R_1, –4
Store R_0, $M[100]$
BNE R_1, 0, loop

(D) loop: ADD R_1, R_1, –4
BNE R_1, 0, loop
Load R_0, $M[100]$
ADD R_0, R_0, 5; Store R_0, $M[100]$;
(Both in single clock cycle)

17. Consider a single level cache with an access time of 2.5 ns, a line size of 64 Bytes and a hit ratio of 0.95. Main memory uses a block transfer capability that has a first word (4 bytes) access time of 60 ns and an access time of 5 ns for each word thereafter.
What is the access time when there is a cache miss, Assume that the cache waits until the line has been fetched from main memory and then re-executes for a hit.

(A) 9.25 ns (B) 9.375 ns
(C) 9.625 ns (D) 9.5 ns

18. For the data given in Q.No:17, Suppose that increasing the line size to 128 bytes increases hit ratio to 0.97, then the average memory access time

(A) increases
(B) decreases
(C) remains constant
(D) will be unpredictable

19. Consider an instruction pipeline with five stages without any branch prediction: Fetch Instruction (FI), Decode instruction (DI), Fetch operand (FO), Execute instruction (EI) and Write operand (WO). The stage delays for FI, DI, FO, EI and WO are 3 ns, 4 ns, 6 ns, 2 ns and 4 ns respectively. There are intermediate storage buffers after each stage and delay of each buffer is 1 ns. A program consisting of 10 instructions $I_1, I_2, ..., I_{10}$ is executed in this pipelined processor. Instruction I_3,

is the only branch instruction and its branch target is I_7. If the branch is taken during the execution of this program, the time needed to complete the program (in nano seconds) is ________.

(A) 49 (B) 56
(C) 98 (D) 105

20. Consider the following program segment for a hypothetical CPU having three user registers R_1, R_2 and R_3.

Instruction	Operation	Instruction size (in words)
MOV R_1, 6000	$R_1 \leftarrow$ M[6000]	2
MOV R_2,(R_1)	$R_2 \leftarrow$ M[(R_1)]	1
SUB R_2, R_3	$R_2 \leftarrow R_2$ - R_3	1
MOV 6000, R_2	M[6000] $\leftarrow R_2$	2
HALT	Machine halts	1

Let the clock cycles required for various operations be as follows:
Instruction fetch and decode: 2 clock cycles per word.
Register to/from memory transfer: 3 clock cycles.
SUB with both operands in registers: 1 clock cycle
Then the total number of clock cycles required to execute the program will be ________.

(A) 2 (B) 23
(C) 24 (D) 19

21. Consider a 32KB, two-way set associative cache with 64-byte block size. The CPU generates 32-bit addresses, A 2-to-1 multiplexer has a latency of 0.5ns while a K-bit comparator has a latency of K/10 ns, then the hit latency of the cache is _______.

(A) 1.8 (B) 2.3
(C) 2.4 (D) 3

22. According to IEEE standard, a 32-bit, single precision, floating point number N is defined to be:
$N = (-1)^S \times 1.\, M \times 2^{E\text{-}127}$
Where S: The sign bit
M: Fractional mantissa
E: The Biased Exponent
A floating point number is stored as SEM, where S, E and M are stored in 1-bit, 8-bits and 23-bits respectively.
What is the value of the floating point number $C0E80000$ (hexa decimal notation)?

(A) –7.25 (B) –29
(C) –0.453 (D) –7

23. For the data given in Q.No. 22, using given notation, what is the hexa decimal equivalent of 565?

(A) 048D4000 (B) 440D4000
(C) 480D4000 (D) 444D4000

24. Consider an 8 KB direct-mapped write-back data cache with 16 byte blocks. The elements of two arrays A and B are 8 bytes long. Array A has 5 rows and 100 columns and array B has 5 rows and 101 columns. (Initially cache is empty). To execute below code, how many cache misses will occur? (Arrays are stored in row-major order).
for (i = 0; i < 5; i++)
for (j = 0; j < 100; j++)
A[i][j] = B[j] [0] * B[j+1][0];

(A) 251 (B) 351
(C) 451 (D) 551

25. Consider a processor with a 5-stage MIPS pipeline (IF, ID, EX, MEM and WB) with no forwarding and each stage takes 1 cycle. The register file can be written and then read in same cycle. In the below program, the destination is the first (left most) register.

Instruction	Operation
LD R_0, (R_2)	$R_0 \leftarrow M(R_2)$
LD R_2, 4(R_3)	$R_2 \leftarrow M[R_3 + 4]$
ADD R_3, R_2, R_0	$R_3 \leftarrow R_2 + R_0$
SUB R_3, R_0, R_0	$R_3 \leftarrow R_0 - R_0$
OR R_4, R_3, 0	$R_4 \leftarrow R_3$ OR 0
SW R_3, 5(R_2)	$R_3 \leftarrow M[R_2 + 5]$

How many stall cycles do the program incur?

(A) 1 (B) 2
(C) 3 (D) 4

26. Consider a deeper pipeline in which, it takes atleast three pipeline stages before the branch-target address is known and an additional cycle before the branch condition is evaluated, assuming no stalls on the registers in the conditional comparison. The 3-stage delay leads to the branch penalties for three simple branch prediction schemes, which are listed below:

Prediction Scheme	Frequency
Unconditional Branch	5%
Conditional branch, Taken	5%
Conditional branch, Untaken	10%

Branch scheme	Penalty (unconditional)	Penalty (taken)	Penalty (Untaken)
Flush Pipeline	2	3	3
Predicted Taken	2	2	3
Predicted Untaken	2	3	0

Find the effective addition to CPI arising from each branch scheme for this pipelining (By taking above frequencies into count)?

(A) 0.5, 0.5, 0.3 (B) 0.3, 0.4, 0.6
(C) 0.55, 0.5, 0.25 (D) 1.3, 1.4, 1.6

27. Assume that the number of clock cycles for a polling operation is 200. Consider a processor which executes at 60 MHz, what is the overhead of polling in percentage

(i) For a mouse that is polled 20 times per second.

(ii) For a hard disk transferring data in 1 word chunks at 1 MB/sec.

(A) 0.006%, 100% (B) 0.0067%, 87.4%
(C) 0.0067%, 43.7% (D) 0.0033%, 43.7%

28. A CPU, which addresses the data through its 8 registers in one of the 15 different modes, is to be designed to support 15 arithmetic instructions, 10 logic instructions, 24 data-moving instructions, 6 branch instructions, 5 control type instructions. Of these instructions respectively 20%, 60%, 50%, 50% and 60% are either single-operand or no-operand instructions and the rest are of double-operand type. What is the minimum size of the CPU's instruction word?

(A) 15-bits (B) 20-bits
(C) 19-bits (D) 21-bits

29. Consider the following sequence of micro-operations:

MAR ← (IR (address))
MBR ← (PC)
PC ← (IR(address))
Memory ← (MBR)
PC ← (PC) + I
I is instruction Length

Which one of the following is a possible operation performed by this sequence?

(A) Instruction fetch
(B) Initiation of interrupt service
(C) Branch-and-save address
(D) Increment and skip if zero.

30. Suppose that a 1 GHz processor needs to read 2000 bytes of data from a particular I/O device. The I/O device supplies 1 byte of data every 0.02 ms. The code to process the data and store it in a buffer takes 1000 cycles.

If the processor detects that a byte of data is ready through polling and a polling iteration takes 80 cycles, how many cycles does the entire operation take?

(A) 42000 K cycles (B) 40000 K cycles
(C) 40080 K cycles (D) 39920 K cycles

31. For the data given in Q. No. 30, If instead, the processor is interrupted when a byte is ready and the processor spends the time between interrupts on another task; then how many cycles are saved by using interrupt-driven over polling technique. The overhead of handling an interrupt is 200 cycles.

(A) 39680 K cycles (B) 39600 K cycles
(C) 38960 K cycles (D) 37680 K cycles

32. A CPU has 64 KB direct mapped cache with 128-byte block size. Suppose X is a two dimensional array of size 512 × 512 with elements that occupy 8-bytes each. Consider the following C-code segment:

```
for (i = 0; i < 512 ; i ++)
{
for (j = 0; j < 512 ; j ++)
{
a+ = X [i] [j];
}
}
```

Initially array X is not in the cache and i, j, a are in registers. The number of cache misses experienced by given code fragment is ________.

(A) 8196 (B) 16384
(C) 32768 (D) 65536

33. Consider the execution of the following sequence of instructions on a five-stage pipeline consisting of:

IF: Instruction Fetch
ID: Instruction Decode
OF: Operand Fetch
IE: Instruction Execution
IS: Store results

Instruction	Operation
LOAD R_1, 1;	$R_1 \leftarrow 1$
LOAD R_2, 5;	$R_2 \leftarrow 5$
SUB R_2, R_2, 1;	$R_2 \leftarrow R_2 - 1$
ADD R_3, R_1, R_2;	$R_3 \leftarrow R_1 + R_2$
ADD R_6, R_4, R_5	$R_6 \leftarrow R_4 + R_5$
SL M[1000], R_3;	$M[1000] \leftarrow R_3$
ADD R_7, R_4, R_6;	$R_7 \leftarrow R_4 + R_6$

The speedup achieved by executing this program on a pipelined processor compared to a sequential processor (Let each stage takes one clock cycle) is _______.

(A) 1.365 (B) 2
(C) 2.1875 (D) 3.236

34. In a program, an array is declared as int A[1024]. Each array element is 2 bytes in size. In main memory the array is stored at the address 0X00000000. This program is run on a computer that has a direct mapped data cache of size 4 KB, with line size of 8 bytes. Which of the following element of the array conflict with the element A[0] in the data cache?

(A) A[256] (B) A[512]
(C) A[63] (D) No conflict

35. For the data given in Q. No. 34, If the program accesses the elements of this array one by one in reverse order that is starting with the last element and ending with the first element, how many data cache misses would occur?

(Assume that the data cache is initially empty and that no other data or instruction accesses are to be considered)

(A) 64 (B) 256
(C) 512 (D) 1024

Answer Keys

1. C	**2.** B	**3.** A	**4.** C	**5.** B	**6.** A	**7.** B	**8.** C	**9.** D	**10.** A
11. B	**12.** C	**13.** A	**14.** C	**15.** B	**16.** A	**17.** B	**18.** B	**19.** C	**20.** C
21. B	**22.** A	**23.** B	**24.** B	**25.** B	**26.** C	**27.** B	**28.** B	**29.** C	**30.** C
31. D	**32.** B	**33.** C	**34.** D	**35.** B					

Hints and Explanations

1. If primary memory has 'M' locations and cache has 'C' locations then each location on the cache is responsible for M/C locations in direct mapping. For 4-way set associative, the cache can hold $4 \times \frac{M}{C}$ locations.
Choice (C)

2. Choice (B)

3. Multiplicand (M) = 23 = 010111
Multiplier (Q) = 29 = 011101
Using unsigned binary multiplication, perform addition if
Q_0 = 1 i.e., LSB of Q register is 1 so number of additions equal to number of '1's in Q. Here number of 1's in Q = 4.
In booth algorithm, perform addition or subtraction if Q_0, Q_{-1} = 01 or 10 respectively. i.e., whenever a bit change occurred, perform either addition or subtraction.
Multiplier (Q) = 0 1 1 1 0 1 0 ← initially Q_{-1} = 0
∴ 4 ADD/SUB operations required.
Hence difference is zero. Choice (A)

4. In write-back case, each dirty line is written back once, i.e., at a swap-out time, taking $\frac{16}{4} \times 20 = 80$ ns.
In write-through case, each update of the line requires that one word be written out to main memory, taking 20 ns.
∴ If the average line that gets written atleast once gets written more then $\frac{80}{20} = 4$ times before swap out, then write back is more efficient. Choice (C)

5. $R_0 \leftarrow x$, $R_1 \leftarrow y$, $R_2 \leftarrow z$
To compute the value $xy + xz + xyz$ on this RISC processor, the operations are
I_1: MUL R_0, R_1, R_3 ... $R_3 \leftarrow xy$
I_2: MUL R_0, R_2, R_4 ... $R_4 \leftarrow xz$
I_3: MUL R_3, R_2, R_5 ... $R_5 \leftarrow xyz$
I_4: ADD R_3, R_4, R_6 ... $R_6 \leftarrow xy + xz$
I_5: ADD R_5, R_6, R_6 ... $R_6 \leftarrow xy + xz + xyz$
Each of I_1, I_2, I_3, I_4 require one clock cycle. I_5 requires two clock cycles as R_6 is used in I_5.
∴ Minimum clock cycles required = 6 Choice (B)

6. Increasing number of stages will increase the throughput but increases latency of single instruction. (III) Condition not valid always. Choice (A)

7. Data in cache = 16 KB = 2^{14}B
Block size = 16 B
Number of blocks $= \frac{2^{14}}{2^4} = 2^{10}$
CPU generates 32-bit addresses.

Tag	Block	Word

Word field requires 4-bits as block size is 16 B. Block field requires 10-bits as there are 2^{10} blocks.
Tag = 32 – (10+4) = 18-bits
∴ Cache size = $2^{10} \times (4 \times 32 + 18)$ = 146 K bits
(as each block has 4 × 32-bit data and 18-bits tag).
Choice (B)

8. Let the two exponents to be added are 13 and 15.
13 in excess - 64 = 13 + 64 = 77 = 1001101
15 in excess - 64 = 15 + 64 = 79 = 1001111
Output from 7-bit parallel adder = 0011100
But 13 + 15 + 64 = 92 = 1011100
Hence complement the MSB of the output.
Choice (C)

9. Opcode field size = 6-bits
∴ Total number of operations possible = 2^6 = 64
Out of these 64, only 20 operations are used by double-operand instructions.
Remaining = 64 – 20 = 44.
In single-operand instructions, src data will be included in opcode field.
∴ Possible single-operand operations = 44×2^4
Out of these only 40 are used for single-operand instructions.
∴ Remaining = 41×2^4
(∵ Three 2^4's are used for single operand instruction)
In zero-operand instructions there will be no operands, so it will be included in opcode field.
∴ Zero-operand instructions
$= 41 \times 2^4 \times 2^4 = 10496$ Choice (D)

10. Address generated by CPU has 32-bits.
Cache memory = 256 KB = 2^{18} Bytes
Block size = 4 words
= 4 × 32 bits (∵ 1 word = 32-bits)
$= \frac{4 \times 32}{8}$ bytes = 16 bytes = 2^4 B

$$\text{Number of lines} = \frac{2^{18}}{2^4} = 2^{14}$$

$$\text{Number of sets} = \frac{2^{14}}{2^2} = 2^{12}$$

Tag	Set	Word
16	12	4

32 bits

Percentage of the cache memory is used for tag bits

$$= \frac{16 \times 2^{14}}{(16+128) \times 2^{14}} \times 100 \text{ } (\because \text{ each block has 128-bits})$$

$$= \frac{16}{16+128} \times 100 = 11.11\%$$ Choice (A)

11. Given numbers 3.67 and 3.45×10^2. To add these two numbers, first align the exponents.
i.e., shift the smaller number to right.
$3.67 = 0.0367 \times 10^2$
The guard digit holds 6 and round digit holds 7.
The sum will be
0.0367
3.4500
3.4867
$\therefore$ Sum $= 3.4867 \times 10^2$
Here we need to round two digits; after rounding sum will be $3.49 \times 10^2 = 349$
Without round and guard digits,
3.45
0.03
3.48
$\therefore$ Sum $= 3.48 \times 10^2 = 348$ Choice (B)

12. 10-bit micro-operation field can be divided into 3 subfields 5, 3, 2 to yield 31, 7, 3 actions respectively. Choice (C)

13. Each stage takes equal amount of time. Let 'x' be the time taken by BIU and EU stages.
Time taken to execute 'n' instructions on this pipeline $= [2 + n - 1]\, x = (n+1)x$
Without pipelining time taken will be $= 2.n.x$

$$\text{Speed up ratio} = \frac{2nx}{(n+1)x}$$

For large number of instructions, $n >> x$.

$$\therefore \text{ Speed up ratio} = \frac{2n}{n} = 2.$$

Hence pipeline improves the performance by a factor of 2. Choice (A)

14. The addressing mode is base with indexing mode.
Displacement = 2970
Base register value = 58022
Index register value = 8
Address of operand = 2970 + 58022 + 8 = 61000
Choice (C)

15. To write one block of data the tasks performed are:
1. Read the parity
2. Read target block old data
3. Compute new parity
4. Write new block
5. Write new parity

$\therefore$ 4 times the blocks are accessed. Choice (B)

16. The first three instructions have data dependencies and so do the last two. The best reorder for these instructions is:

Loop:	ALU/branch instruction	LOAD/STORE instruction	Clock cycle
		LOAD R_0, M[100]	1
	ADD R_1, R_1, –4		2
	ADD R_0, R_0, 5		3
	BNE R_1, 0, Loop	STORE R_0, M[100]	4

Hence only one pair of instructions has both issue slots used. Choice (A)

17. Cache access time = 2.5 ns
Line size = 64 Bytes
Hit ratio = 0.95
Access time of first byte in main memory = 60 ns
Next word access time = 5 ns

$$\text{Number of words in each line} = \frac{64}{4} = 16 \text{ words}$$

For 1st word 60 ns and for remaining 15 words, 15×5 ns required.
Cache access time when there is a miss
$= 0.95 \times 2.5 + 0.05\,(2.5 + 60 + 15 \times 5 + 2.5)$
$= 9.375$ ns Choice (B)

18. New line size = 128 bytes
$H = 0.97$

$$\text{Now, words in each line} = \frac{128}{4} = 32$$

First word requires 60 ns and remaining 31 words require 31×5 ns.
$\therefore$ Cache access time when there is a miss
$= 0.97 \times 2.5 + 0.03 \times (2.5 + 60 + 31 \times 5 + 2.5)$
$= 9.025$
$\therefore$ Average memory access time reduced.
Choice (B)

19. Stage delays for FI, DI, FO, EI and WO are 3, 4, 6, 2, 4 ns respectively.
Maximum time is taken by FO. i.e., 6 ns and additional 1 ns is required for delay. So total time for an instruction to pass from one stage to another is 7 ns. The instruction execution sequence is $I_1, I_2, I_3, I_7, I_8, I_9, I_{10}$.
When I_3, is in its execution stage, we detect the branch and when I_3 is in 'WO' stage we fetch I_7.
Execution time for $I_1, I_2, I_3 = [5 + (3 - 1)]\, 7 = 49$ ns.

Execution time for $I_7, I_8, I_9, I_{10} = [5 + (4 – 1)]7 = 56$ ns
But we fetch I_7 in I_3's WO stage, so we saved 7 ns
Hence total time = 49 + 56 – 7 = 98 ns.

Choice (C)

20. Each instruction requires fetch and decode stage.

	Fetch & Decode	Operation
MOV R_1, 6000	2 × 2	3
MOV R_2, (R_1)	2	3
SUB R_2, R_3	2	1
MOV 6000, R_2	2 × 2	3
HALT	2	–

∴ Total clock cycles required = 7 + 5 + 3 + 7 + 2 = 24

Choice (C)

21. Cache capacity = 32 KB = 2^{15}B
Block size = 64B = 2^6B
∴ word size = 6-bits.

The cache is 2-way set associative, so $2 \times 2^v = \frac{2^{15}}{2^6}$

⇒ $2^V = 2^8$
∴ set size = 8-bits
CPU generates 32-bit addresses.

← 32 →

Tag	Set	Word
← 18 →	← 8 →	← 6 →

First a 2-to-1 multiplexer is required whose latency is 0.5 ns. After that the tag bits are compared using a comparator.

For 18-bit comparator $\frac{18}{10}$ ns required.

∴ Hit latency = 0.5 + 1.8 = 2.3 ns

Choice (B).

22. Given number $C0E80000$
In binary, it will be

← 32 →

1 | 100 00001 | 110 1000 0000 0000 0000 0000

sign, exponent, mantissa

$S = 1$
$E = 100\ 00001 = 129$
Mantissa = 110 1000 0000 0000 0000 0000
∴ $N = (–1)^1 \times 1.1101 \times 2^{129–127}$
$= –1.1101 \times 2^2$
$= –111.01 = –7.25$

Choice (A)

23. 565 = 1000110101
$N = (–1)^0 \times 1.000110101 \times 2^{136–127}$
IEEE standard binary equivalent of
N = <u>0 100</u> <u>0 100</u> <u>0 000</u> <u>1101</u> <u>0100</u> <u>0000</u> <u>0000</u> <u>0000</u>
4 4 0 D 4 0 0 0
= 440D4000

Choice (B)

24. Elements of "A" are written in the order in which they are stored in memory. So A will benefit from spatial locality. The even values of j will miss and odd values will hit. i.e., Each block consists two values. (For example a[0] [0] , a[0] [1] or a[0] [2], a[0] [3] etc.)
Since A has 5 rows and 100 columns, its accesses will lead to $5 \times \frac{100}{2} = 250$ misses.
The array 'B' does not benefit from spatial locality since the accesses are not in the order it is stored. But it will benefit from temporal locality.
The misses due to 'B' will be for $B[j + 1]$ [0] accesses when i = 0 and also the first access to $B[j][0]$ when j = 0. Since j goes from j = 0 to 99 when i = 0, accesses to B lead to 100 + 1 or 101 misses.
∴ Total cache misses = 250 + 101 = 351.

Choice (B)

25. There are only two stall cycles. One is after 2nd load as R_2 is immediately required in ADD instruction. Another stall is after 'SUB' as $R3$ is immediately required by 'OR' instruction. Choice (B)

26. We find the CPI's of each prediction by multiplying the relative frequencies with respective penalties.

Branch scheme	**Frequency**	**Unconditional**	**Conditional, Taken**	**Conditional, Untaken**
Stall Pipeline	5%	$\frac{5}{100} \times 2 = 0.1$	$\frac{5}{100} \times 3 = 0.15$	$\frac{10}{100} \times 3 = 0.3$
Predicted Taken	5%	$\frac{5}{100} \times 2 = 0.1$	$\frac{5}{100} \times 2 = 0.1$	$\frac{10}{100} \times 3 = 0.3$
Predicted Untaken	10%	$\frac{5}{100} \times 2 = 0.1$	$\frac{5}{100} \times 3 = 0.15$	$\frac{10}{100} \times 0 = 0$

Total branches frequency = 5 + 5 + 10 = 20%

Using stall pipeline, additional CPI = 0.1 + 0.15 + 0.3 = 0.55
Using predicted taken, additional CPI = 0.1 + 0.1 + 0.3 = 0.5
Using predicted Untaken, additional CPI = 0.1 + 0.15 + 0 = 0.25 Choice (C)

27. Clock cycles per second used for polling a mouse = 20 × 200 = 4000
Fraction of processor cycles used for polling

$$= \frac{4000}{60 \times 10^6} \times 100 = 0.0067\%$$

Rate of polling for hard disk $\dfrac{\frac{1\text{ MB}}{\text{sec}}}{4\text{ bytes per access}}$

= 262144 polling access per second
Clock cycles = 262144 × 200 = 52428800
∴ Fraction of CPU cycles

$$= \frac{52428800}{60 \times 10^6} \times 100 \times 100 = 87.4\%$$ Choice (B)

28. Double-operand instruction format will be

Opcode	Src data	Dest Data

Data will consist both mode and register field.
There are 8-registers, so 3-bits required. For 15-different modes 4-bits required.
∴ Each data field requires 7-bits.
Now we need to find opcode size.

	Instruction	Single/ no-operand	Double-operand
Arithmetic	15	$3\left(\frac{20}{100} \times 15\right)$	12
Logic	10	6	4
Data-moving	24	12	12
Branch	6	3	3
Control	5	3	2

∴ Total double operand instructions = 12 + 4 + 12 + 3 + 2 = 33
6-bits required for double operand. (∵ $2^6 > 33$).
∴ Minimum size of CPU's instruction word = 6 + 7 + 7 = 20-bits. Choice (B)

29. Given micro-operations specifies Branch-and-save address. The address part in instruction is extracted. Next instruction address is saved to memory location and execution continues at location (PC) + I. Choice (C)

30. Polling is same as programmed-I/O
Number of cycles required for polling
= 1 × 10^9 × 0.02 × 10^{-3} = 20000
Before processing the data it will be
20000 – 1000 = 19000 cycles
Each polling iteration takes 80 cycles.
∴ Number of polls required for one byte $= \frac{19000}{80}$
= 237.5 polls ≃ 238 polls
Cycles spend on polling = 238 × 80 = 19040 cycles
∴ Each byte thus take 19040 + 1000 = 20040 cycles
To read 2000 bytes it requires
2000 × 20040 = 40080000
= 40080 K cycles Choice (C)

31. Each byte takes 200 + 1000 = 1200 cycles
i.e., 1200 cycles to process a byte.
For 2000 bytes it will required
1200 × 2000 = 2400000 cycles
Number of cycles saved using interrupt method
= 40080000 – 2400000 = 37680 K cycles Choice (D)

32. Cache size = 64 KB = 2^{16} B
Block size = 128-Bytes = 2^7 B
Array size = 512 × 512
Each element requires 8 bytes.
Memory required to store X is $512 \times 512 \times 8 = 2^{21}$ Bytes.
Number of Blocks required to store 2^{21} Bytes

$$= \frac{2^{21}}{2^7} = 2^{14} = 16384$$

∴ Number of cache misses = 16384 Choice (B)

33. Time required to execute given program on a sequential processor = 7 × 5 = 35

On a pipelined processor the execution sequence is shown below:

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
I1	IF	ID	OF	IE	IS											
I2		IF	ID	OF	IE	IS										
I3			IF	ID			OF	IE	IS							
I4				IF	ID					OF	IE	IS				
I5					IF	ID					OF	IE	IS			
I6						IF	ID						OF	IE	IS	
I7							IF	ID						OF	IE	IS

∴ Total number of clock cycles required = 16

∴ Speed-up

$$= \frac{\text{Time required on sequential processor}}{\text{Time required on pipelined processor}} = \frac{35}{16}$$

= 2.1875 Choice (C)

34. Array is $A[1024]$
Array requires 1024 × 2 bytes.
Cache size = 4 KB = 2^{12} B
Line size = 8 bytes

Number of lines $= \frac{2^{12}}{2^3} = 2^9$ lines

Array requires 2048 bytes

i.e., $\frac{2048}{8}$ = 256 blocks. As number of lines is greater than the blocks required for array storage, there will be no conflict with element $A[0]$.

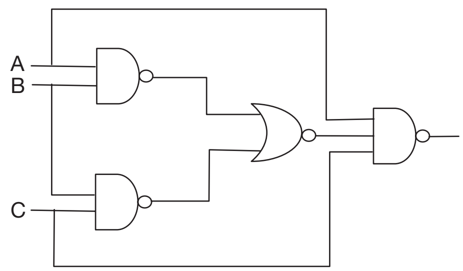
Choice (D)

35. As the array requires 2048 bytes i.e., $\frac{2048}{8}$ = 256 blocks, 256 misses will be there. Choice (B)

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. The output of the following circuit is:



(A) $\overline{A}\overline{B}+\overline{B}\overline{C}$ (B) $\overline{A}\overline{B}+\overline{B}\overline{C}+\overline{A}\overline{C}$
(C) $\overline{A}+\overline{B}+\overline{C}$ (D) $\overline{AB+BC}$

2. Match the following:
List I (Numbers in Decimal)
List II (equivalents in signed 2's complement representation)

	List-I		List-II
P.	– 43	1.	01100000
Q.	– 78	2.	00110110
R.	+ 54	3.	111010101
S.	+ 96	4.	10110010

(A) P–3, Q–4, R–1, S–2
(B) P–4, Q–3, R–1, S–2
(C) P–3, Q–4, R–2, S–1
(D) P–4, Q–3, R–1, S–2

3. Which one of the following function will satisfy the property, "Dual of function = complement of the function"?
(A) $f(A, B, C) = \Sigma m\ (0, 1, 2, 3)$
(B) $f(A, B, C) = \Sigma m\ (4, 5, 6, 7)$
(C) $f(A, B, C) = \Sigma m\ (0, 2, 4, 6)$
(D) $f(A, B, C) = \Sigma m\ (0, 1, 6, 7)$

4. The number of min terms for the function
$F(a, b, c, d, e) = b + cd$ is:
(A) 24 (B) 20
(C) 32 (D) 16

5. Which of the following will work like an inverter?

(P) 
(Q) 
(R) 
(S) 
(A) P, Q (B) Q, R
(C) R, S (D) P, S

6. Perform the following operation in 2's complement signed representation, and specify the result in 2's complement signed notation.

$$(-13)_{10} + (-28)_{10} = ?$$

(A) 10101001 (B) 11010111
(C) 11010110 (D) 00101001

7. Convert the following number to base 9.

$$(1101222.201121)_3$$

(A) 1358.647 (B) 4172.647
(C) 4178.153 (D) 1358.153

8. Which of the following is usually regarded as a bottleneck to von-Neumann computer Architecture?
(A) ALU
(B) Instruction set
(C) Processor/memory interface
(D) Control unit

9. Which of the following is the largest storage unit in a usual memory hierarchy?
(A) Cache memory (B) Main memory
(C) Register (D) Hard disk

10. Which type of cache miss does not occur in fully-Associative cache memory?
(A) Capacity miss (B) Conflict miss
(C) Compulsory miss (D) Cold start miss

11. Which of the following statement is FALSE?
(A) Pipelining does not improve the execution time of a single task.
(B) Pipelining improves the throughput of the total work load.
(C) Pipeline speed is limited by the slowest pipeline stage.
(D) In pipelining, only one task is processed at a time.

12. What is the execution time per stage of a pipeline that has 4 equal stages and a mean overhead of 12 cycles?
(A) 3 cycles (B) 4 cycles
(C) 6 cycles (D) 12 cycles

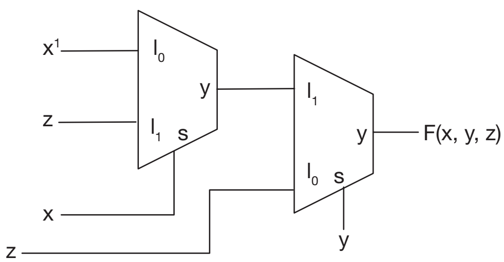
13. How many bits are needed to represent a direct address on a 64-bit machine?
(A) 6-bits (B) 64-bits
(C) 32-bits (D) 2^{64}-bits

14. A program has 5% divide instructions. Any non-divide instruction takes one cycle. All divide instructions take 25 cycles. What percent of CPU time is spent just doing divides?
(A) 100% (B) 95%
(C) 56.82% (D) 28.41%

15. Which of the following is not an advantage of memory mapped technique?
(i) Simple hardware
(ii) Simple instruction size
(iii) All address modes available
(iv) More memory address space
(A) (i), (iv) only (B) (iv) only
(C) (i), (ii), (iii) only (D) (iii), (iv) only

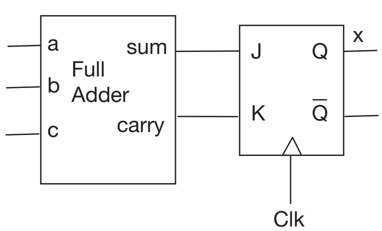
16. How many number of 2-input NAND gates are required to implement $f(A, B, C, D) = \Sigma m$ (1, 3, 4, 5, 6, 7, 9, 11, 12, 13, 14, 15)?
(A) 4 (B) 3
(C) 2 (D) 1

17. The output of the following Multiplexer circuit is:



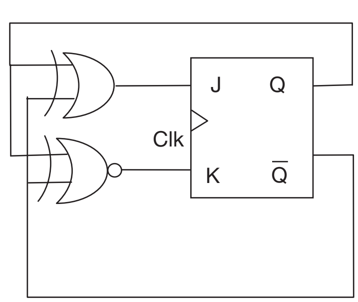
(A) $x^1 + yz$ (B) $x^1 y + z$
(C) $(x^1 + y)z$ (D) $x^1 y^1 + yz + xy^1 z$

18. Initially $Q_n = 0$, $\bar{Q}_n = 1$, , after clock pulse $Q_{n+1} = 1$, $\bar{Q}_{n+1} = 0$, which of the following correctly specifies about the inputs a, b, c?



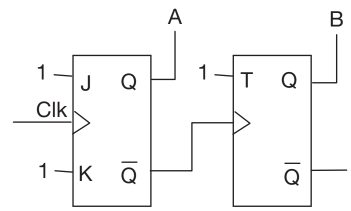
(A) two or more inputs should be 1.
(B) only one input has to be 1, or all inputs should be 1.
(C) c should be zero, a, b, can be either 11 or 00
(D) All inputs should be zero.

19. The states of Q, $\bar{Q}$ after a clock pulse are:



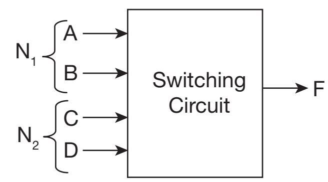
(A) 0, 1 (B) 1, 0
(C) 1, 1
(D) cannot be determined without initial states

20. The initial state of counter is $AB = 01$. What is the output (AB) after first clock pulse?



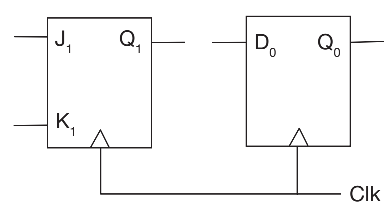
(A) 10 (B) 11
(C) 01 (D) 00

21. A switching circuit has four inputs as shown below. A and B represent the first and second bits of a binary number N_1, C and D represent the first and second bits of a binary number N_2.
The output is 1 only, if the product $N_1 \times N_2$ is less than or equal to 2.
The minimum POS form of $F(A, B, C, D)$ is



(A) $\bar{A}\bar{B} + \bar{C}\bar{D} + \bar{A}\bar{C} + \bar{A}\bar{D} + \bar{B}\bar{C}$
(B) $(A + C)(A + B + D)(B + C + D)$
(C) $(\bar{A} + \bar{D})(\bar{A} + \bar{B} + \bar{D})(\bar{B} + C + \bar{D})$
(D) $(\bar{A} + \bar{C})(\bar{A} + \bar{B} + \bar{D})(\bar{B} + \bar{C} + \bar{D})$

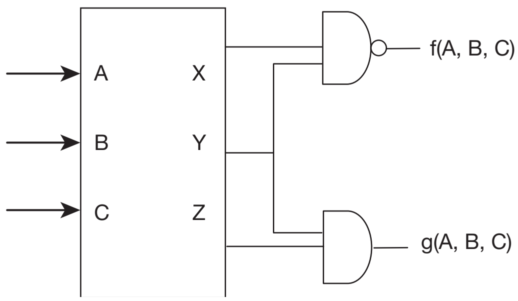
22. The synchronous counter which follows ($Q_1\ Q_0$) $00 \to 10 \to 11 \to 01 \to 00$ by using JK-flip flop and D-flip flop, has inputs as



(A) $J_1 = \bar{Q}_1, K_1 = Q_0, D_0 = Q_0$
(B) $J_1 = Q_1, K_1 = \bar{Q}_1, D_0 = Q_0$
(C) $J_1 = \bar{Q}_0, K_1 = Q_0, D_0 = Q_1$
(D) $J_1 = Q_0, K_1 = \bar{Q}_0, D_0 = Q_1$

23. The minimum SOP form of:
(A) $\bar{P} + QR$ (B) $\bar{P} + Q$
(C) $\bar{P}\bar{Q} + R$ (D) P

24. A combinational circuit has 3 inputs A, B, C, and 3 outputs X, Y, Z. And the functions $f(A, B, C)$ and $g(A, B, C)$ are generated from the combinational logic circuit as shown here with NAND, AND gates. Find the least possible minterm expression for $Y(A, B, C)$.
$f(A, B, C) = \Sigma m(1, 3, 4, 5, 7)$
$g(A, B, C) = \Sigma m(4, 6)$
$Y(A, B, C) = \Sigma m(?)$



(A) $\Sigma m(0, 2, 3, 6, 7)$ (B) $\Sigma m(1, 3, 4, 5, 7)$
(C) $\Sigma m(0, 2, 4, 6)$ (D) $\Sigma m(0, 2, 4)$

25. From the above data, for which input A, B, C. The outputs all X, Y, Z will become 111 (i.e., $XYZ = 1$)
(A) 010 (B) 101
(C) 100 (D) 110

26. What is the speed up of the pipeline, which is executing 10 tasks. Consider the mean overhead of the pipeline as 5 and an execution time per stage as 1 cycle.
(A) 4.5 (B) 4
(C) 3 (D) 5

27. Consider a 32-bit computer that has an on-chip 16 Kbyte four-way set-associative cache. Assume that the cache has a line size of four 32-bit words. Then what will be Tag, Set and Word fields respectively:
(A) 18, 8, 6 (B) 18, 10, 4
(C) 20, 8, 4 (D) 20, 10, 2

28. Consider a memory of 64 blocks (labelled 0 through 63) and a cache of 8 lines (labelled 0 through 7). Using direct mapping, which of the following blocks of memory contend for line 2 of the cache?
(i) Block 10 (ii) Block 15
(iii) Block 20 (iv) Block 55
(v) Block 42 (vi) Block 63
(A) (i), (iii), (v) only (B) (i), (v) only
(C) (i), (ii), (iv) only (D) All the six

29. Convert the decimal number –30.375 to IEEE 754 Floating-point format. Which of the following correctly specifies the hexa-decimal equivalent of converted number?
(A) C1F30000 (B) 82830000
(C) 02830000 (D) 41F30000

30. Consider a main memory system that consists of Eight memory modules attached to the system bus, which is one word wide. When a write request is made the bus in occupied for 100 ns by the data, address and control signals. During the same 100 ns and for 500 ns thereafter, the addressed memory module executes one cycle accepting and storing the data. The internal operation of different memory modules may overlap in time, but only one request can be on the bus at any time. What is the maximum number of stores that can be initiated in one second?
(A) 10^9 (B) 10^7
(C) 10^5 (D) 10^2

31. Suppose a bus protocol requires 15 ns for devices to make requests, 15 ns for arbitration and 20 ns to complete each operation. How many operations can be completed per second?
(A) 10^7 (B) 2×10^7
(C) 5×10^7 (D) 50

32. A computer truncates the significant to four decimal places and gives the results in normalized form. What is the resultant of $(0.2233 \times 10^2) + (0.6688 \times 10^1)$?
(A) 0.2901×10^2 (B) 2.9018×10^1
(C) 0.2902×10^2 (D) 29.018

33. For each of the following cases, specify whether SRAM or DRAM would be more appropriate building block for the memory system?
(i) A memory system where performance is the most important goal.
(ii) A memory system where cost is the most important goal.
(A) SRAM, SRAM
(B) SRAM, DRAM
(C) DRAM, SRAM
(D) DRAM, DRAM

Linked answer questions 34 and 35:
Consider an unpipelined processor. Assume that it has 1 ns clock cycle and it uses 3 cycles for ALU operations, 5 cycles for branch instructions and 4 cycles for memory operations. Assume that the relative frequencies of these operations are 80%, 10% and 10% respectively. Suppose that due to clock skew and set up, pipelining the processor adds 0.1 ns of overhead to the clock.

34. What is the average instruction execution time on a pipelined processor?
(A) 4.3 ns (B) 4.4 ns
(C) 1.1 ns (D) 1 ns

35. By ignoring latency impact, what is the speedup gain in the instruction execution rate using pipeline?
(A) 4.3 (B) 3.9
(C) 1.1 (D) 1

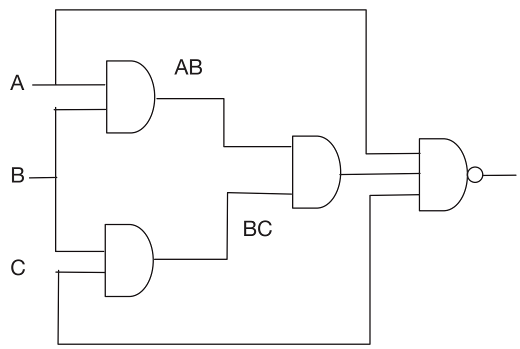
Hints and Explanations

1. In the circuit NAND – NOR structure can be redrawn as AND – AND Structure.



$\overline{A \cdot ABC \cdot C} = \overline{ABC} = \bar{A} + \bar{B} + \bar{C}$ Choice (C)

2. Positive numbers will be represented in their original binary magnitude but sign bit will be zero (0) to make it as positive number.
Negative Numbers are represented as 2's complement of their positive number representation in 2's complement signed number.
+ 43 = 00101011
– 43 = 11010101 (By taking 2's complement)
+ 78 = 01001110
– 78 = 10110010 (By taking 2's complement)
+ 54 = 00110110
+ 96 = 01100000 Choice (C)

3. Dual of function can be obtained by making min terms to max terms, i.e., 0 to 1, 1 to 0.
Dual of
000 $\leftrightarrow$ 111
001 $\leftrightarrow$ 110
010 $\leftrightarrow$ 101
011 $\leftrightarrow$ 100
$f = \Sigma m\ (0, 1, 6, 7)$
Dual is $f^D = \pi\ m\ (7, 6, 1, 0)$
$= \pi\ m\ (0, 1, 6, 7)$
$= \Sigma\ m\ (2, 3, 4, 5)$
Which is equal to $\bar{f}$ (complement of f). Choice (D)

4. $F = b + cd$
The term 'b' = - b - - - will have 16 min terms, the term cd = - - cd - will have 8 min terms out of those 4 min terms, have 'b'.
So remaining are 8 – 4 = 4
So total min terms = 16 + 4 = 20 Choice (B)

5. P is $1 \oplus A = \bar{A} \cdot 1 + A \cdot \bar{1} = \bar{A}$
Q is $A \odot 0 = \bar{A} \cdot 1 + A \cdot 0 = \bar{A}$
R is $0 \oplus A = \bar{A} \cdot 0 + A \cdot \bar{0} = A$
S is $1 \odot A = 1 \cdot A + 0 \cdot \bar{A} = A$
So P, Q work like inverter. Choice (A)

6. $(-13)_{10} + (-28)_{10} = (-41)_{10}$
The operation in 2's complement signed representation also given the same answer.
$(-41)_{10}$ is signed 2's complement representation is 11010111 ($\because$ +41 = 00101001) Choice (B)

7. Base 9 and base 3 are related ($3^2 = 9^1$). 2 digits of base 3 is equal to base 9.

Base-3	Base-9
01	1
02	2
10	3
11	4
12	5
20	6
21	7
22	8
100	10

Given number in base 3 is
$\underline{01}\ \underline{10}\ \underline{12}\ \underline{22} \cdot \underline{20}\ \underline{11}\ \underline{21}$
1 3 5 8 · 6 4 7
$= (1358 \cdot 647)_9$ Choice (A)

8. In Von-Neumann computer architecture, most of the time is used for transferring data or instructions from memory to CPU. This is the bottleneck of Von-Neumann computer. Choice (C)

9. Choice (D)

10. In full-Associative cache, we can place any block of main memory at any line of cache. So there will be no conflict miss. Choice (B)

11. In pipelining, several tasks are processed simultaneously. Choice (D)

12. If there are k stages and each stage take T cycles then $(k - 1)\ T$ = Pipeline mean overhead
$\Rightarrow$ $(4 - 1) \times T = 12$
$\Rightarrow$ $T = 4$ cycles. Choice (B)

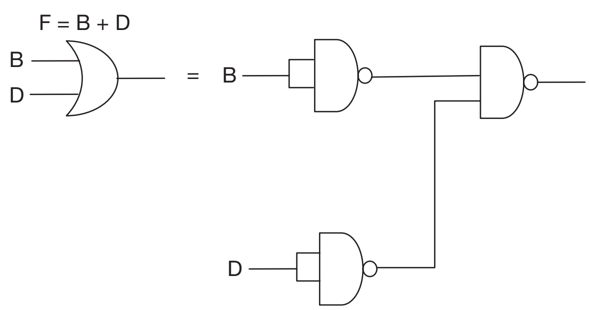
13. A 64-bit machine has 2^{64} locations. To address these locations, we require 64-bits. Choice (B)

14. Total time required to execute the given program
$= (0.95) * 1 + (0.05) * 25 = 0.95 + 1.25 = 2.2$
Time taken for Divide Operations $= 0.05 * 25 = 1.25$
$\therefore$ Percentage of CPU time spent on divides
$= \frac{1.25}{2.2} * 100 = 56.82\%.$ Choice (C)

15. Using memory mapped technique, the memory address space will be reduced. Choice (B)

16. $f(A, B, C, D) = \Sigma m\,(1, 3, 4, 5, 6, 7, 9, 11, 12, 13, 14, 15)$

AB \ CD	00	01	11	10
00		1	1	
01	1	1	1	1
11	1	1	1	1
10		1	1	



$F = B + D$. So 3, 2–input NAND gates are required to implement $F(A, B, C, D)$

Choice (B)

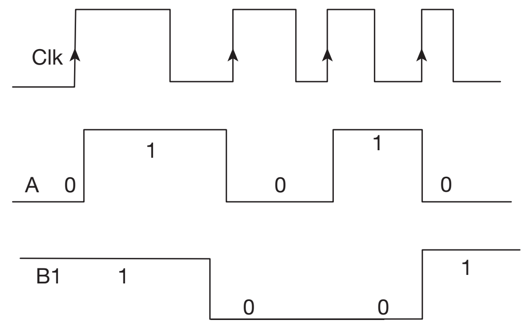
17. The first multiplexer output is
$y = I_0\bar{s} + I_1 s$
$= x^1 \cdot x^1 + zx = x^1 + zx = x^1 + z$
$F = (x^1 + z)y + z \cdot y^1 = x^1 y + yz + y^1 z$
$= x^1\, y + (y + y^1)z = x^1\, y + z$ Choice (B)

18. $Q_n = 0, Q_{n+1} = 1$
i.e., the state gets toggled i.e., when $J = 1, K = 1$
or the next state is set, $Q_{n+1} = 1$ i.e., when $J = 1, K = 0$
so $J = 1, k = x$ (either zero or 1)
so sum should be one, carry either zero or one.
So a, b, c should have only one 1 (sum = 1, carr$y$ = 0)
All inputs a, b, c can be 1 so that sum = 1, carr$y$ = 1.
Choice (B)

19. $J = Q_n \oplus \bar{Q}_n$(EXOR of $Q, \bar{Q}$) $= 1$
$K = Q_n \,\Theta\, \bar{Q}_n$(EXNOR of $Q, \bar{Q}$) $= 0$
When $J = 1, K = 0$, next clock pulse will give
$Q = 1,\ \bar{Q} = 0$ Choice (B)

20. Given circuit is an Asynchronous counter, as clock is connected to rising edge.

$\bar{Q}$ connected to rising edge means this is an UP counter A is LSB, B is MSB.
$\bar{Q}_A$ connected to rising edge.
i.e., for every falling edge of Q_A, B will change so $AB = 11$



Clk	BA
0	10
1	11
2	00
3	01
4	10

$\bar{Q}_A$ connected to rising edge.
i.e., for every falling edge of Q_A, B will change so $AB = 11$ Choice (B)

21.

N_1	AB \ CD (N_2)	00 (0)	01 (1)	11 (3)	10 (2)
0	00	1	1	1	1
1	01	1	1		1
3	11	1			
2	10	1	1		

The max terms will be (for POS form)

AB \ CD	00	01	11	10
00				
01			0	
11		0	0	0
10			0	0

So $F = (\bar{A} + \bar{C})(\bar{B} + \bar{C} + \bar{D})(\bar{A} + \bar{B} + \bar{D})$ Choice (D)

22.

Present state		Next state		Inputs		
Q_1	Q_0	Q_1	Q_0	J_1	K_1	D_0
0	0	1	0	1	X	0
1	0	1	1	X	0	1
1	1	0	1	X	1	1
0	1	0	0	0	X	0

From the above table,
Writing the inputs interms of present state
$D_0 = Q_1, J_1 = \bar{Q}_0,\ K_1 = Q_0$ Choice (C)

23. Given function is in standard POS Form
$F(P, Q, R) = \pi M\ (5, 6, 4) = \Sigma m\ (0, 1, 2, 3, 7)$

P \ QR	00	01	11	10
0	1	1	1	1
1			1	

$F\ (P, Q, R) = \bar{P} + QR$ Choice (A)

24. When we consider two min terms product,
$m_i, m_j = 0$ if $i \neq j$
e.x., $A\bar{B}C \cdot A\bar{B}\bar{C} = 0$ $m_i, m_j \neq 0$ if $i = j$
e.x., $A\bar{B}\bar{C}\ A\bar{B}\bar{C} = A\bar{B}\bar{C}$
If two functions ANDed with min terms, then resultant is common min terms of the two functions.
Example:
If $f_1\ (a, b, c) = m_1 + m_2 + m_3$
$f_2\ (a, b, c) = m_3 + m_4$
$f_1 \cdot f_2 = (m_1 + m_2 + m_3)\ (m_3 + m_4)$
$= m_1 \cdot m_3 + m_1 \cdot m_4 + m_2 \cdot m_3 + m_2 m_4 + m_3 \cdot m_3 + m_3 \cdot m_4$
$= m_3$ (all other terms will be zero)
In the given problem $f(A, B, C) = \overline{X \cdot Y}$
$= \Sigma m(1, 3, 4, 5, 7)$
So $X, Y = \Sigma m\ (0, 2, 6)$ (the remaining min terms)
$g(A, B, C) = Y \cdot Z = \Sigma m\ (4, 6)$
X and Y are having (0, 2, 6) min terms in common, i.e., Y will have all these 3 min terms.
Similarly Y and Z have (4, 6) min terms in common,
So Y will have these 2 min terms also.
So $Y = \Sigma m\ (0, 2, 4, 6)$ Choice (C)

25. From the above solution
$f(A, B, C) = \overline{XY} = \Sigma m\ (1, 3, 4, 5, 7)$
$X \cdot Y = \Sigma m\ (0, 2, 6)$
$g\ (A, B, C) = Y\,Z = \Sigma m(4, 6)$
The min terms common to $X\,Y$ and $Y\,Z$ are
$XY \cdot YZ = XYZ = \Sigma m\ (6)$
i.e., The output $X = 1, Y = 1, Z = 1$ only for the min term 6, i.e., $ABC = 110$. Choice (D)

26. Pipeline mean overhead = 5
Let there are k stages.
Given each stage take 1 cycle.
$(k - 1)T$ = Pipeline overhead
$\Rightarrow\ (k - 1) \times 1 = 5$
$\Rightarrow\ k = 6$

$$\text{Speed up} = \frac{\text{nonpipeline execution time}}{\text{pipeline execution time}}$$

$$= \frac{10 \times 6}{(10 + 6 - 1)} = \frac{60}{15} = 4$$ Choice (B)

27.

Tag	Set	Word
20	8	4

32-bits

32-bits
Cache capacity = 16 KB = 2^{14} bytes
Line size = 4 × 32-bit words
= 4 × 4 Bytes = 16 Bytes = 2^4B

$$\text{Number of lines in cache} = \frac{2^{14}}{2^4} = 2^{10}$$

4 × Number of sets = 2^{10}
$\Rightarrow$ Number of sets = 2^8
$\therefore$ Set size = 8
Tag = 32 – (8 + 4) = 20. Choice (C)

28. Main memory has 64-blocks (0 – 63).
Cache has 8 lines (0 – 7).
To place a particular block of main memory in a line of cache, use the following formula:
Cache line number = Block number % number of cache lines.
In cache line number 2, at a time any one of the blocks 2, 10, 18, 26, 34, ..., 58 can be placed. Choice (B)

29. $-30.375 = -11110.011 = -1.1110011 \times 2^4$
Sign = 1
Mantissa = 11100110000000000000000
Exponent = 4
Biased exponent = 127 + 4 = 131 = 10000011
$\therefore$ –30.375 in IEEE standard is

$$\begin{array}{cccccccc} \underline{1100} & \underline{0001} & \underline{1\,111} & \underline{0011} & \underline{0000} & \underline{0\,000} & \underline{0\,000} & \underline{0\,000} \\ C & 1 & F & 3 & 0 & 0 & 0 & 0 \end{array}$$

$= (C1F30000)_{16}$. Choice (A)

30. First write operation requires 600 ns. (100 ns for bus, 500 ns for store)
During the store operation of first write another request may be given to bus.
So we can start a write operation after every 100 ns.
$\therefore$ Maximum number of stores that can be initiated in

$$\text{one second} = \frac{1}{100\text{ ns}} = \frac{10^9}{10^2} = 10^7$$ Choice (B)

31. Total time taken for one operation = 15 + 15 + 20 = 50 ns

One operation requires 50×10^{-9} sec
In one second, number of operations completed

$= \dfrac{1}{50 \times 10^{-9}} = 2 \times 10^{7}$. Choice (B)

32. 0.2233×10^{2}
$+0.6688 \times 10^{1}$
?

First equate the exponents
$0.6688 \times 10^{1} = 0.06688 \times 10^{2}$
0.22330×10^{2}
0.06688×10^{2}
0.29018×10^{2}

The resultant must have four decimal places (by truncation)
$\therefore$ Sum is 0.2901×10^{2}. Choice (A)

33. For high performance use SRAM and for low cost use DRAM. Choice (B)

34. Average instruction time on a pipelined processor
= 1 ns + 0.1 ns = 1.1 ns. Choice (C)

35. Average instruction time on a non-pipelined processor
$= 1 + ((3 \times 0.8) + (5 \times 0.1) + (4 \times 0.1)) = 4.3$ ns

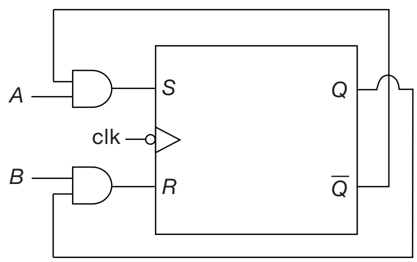
Speed up $= \dfrac{4.3}{1.1} = 3.9$ Choice (B)

Digital Logic and Computer Organization and Architecture Test 6

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices

1. The following flip flop is

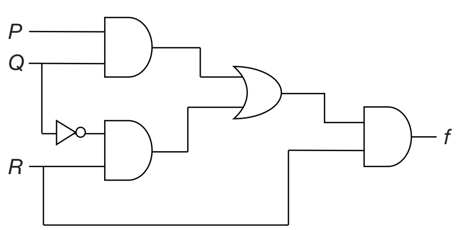


(A) D flip flop when $A = 0$
(B) D flip flop when $A = B$
(C) T flip flop when $A = 0$
(D) T flip flop when $A = B$

2. If $a \le b$, which of the following is true
(P) $a^1 + b = 1$ (Q) $a^1 \le b^1$
(R) $ab^1 = 0$
(A) P, Q (B) P, R
(C) Q, R (D) P, Q, R

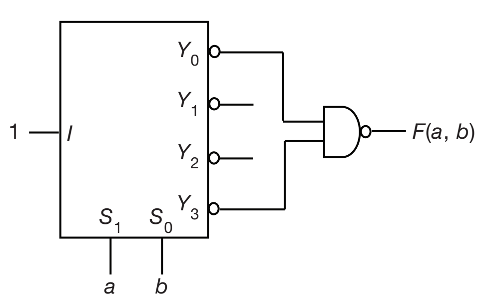
3. If $a = (b + c)\,(b^1 + c^1)$, then the value of b is:
(A) $(a^1 + c)\,(a + c^1)$ (B) $a^1c + ac^1$
(C) $a^1c^1 + a^1c$ (D) $(a^1 + c^1)(a + c^1)$

4. Calculate switching function realized by this network in minimized SOP form



(A) $PQ + \bar{Q}R$ (B) $PQR + \bar{Q}R$
(C) $PR + \bar{Q}R$ (D) $P\bar{Q} + R$

5.



In the above circuit the function $F(a, b)$ in POS form
(A) $(a + b)(a^1 + b^1)$ (B) $(a^1 + b)(a + b^1)$
(C) $(a + b^1)(a^1 + b^1)$ (D) $(a + b)(a^1 + b)$

6. A combinational circuit takes input in the range of 000 to 101, (remaining combinations are unused) The output of the circuit is 1 when ever input is a power of 2 (in decimal). Find the minimized expression for output, if x, y, z are inputs of the combinational circuit.
(A) $x^1\, y \oplus z^1$ (B) $(x + y) \odot z$
(C) $x^1\, y^1 \oplus z$ (D) $(x + y) \oplus z$

7. A boolean function defined as $f(a, b, c, d, e) = b + d\,(c + ae)$
How many number of min terms will be present for the function $f(a, b, c, d, e)$?
(A) 20 (B) 24
(C) 28 (D) 16

8. The characteristic equation of the flip-flop with functional table given below is, $(Q_{n+1}) =$

X Y	Q_{n+1}
0 0	$\overline{Q_n}$
0 1	1
1 0	0
1 1	Q_n

(A) $\bar{X}Q_n + Y\bar{Q}_n$ (B) $\bar{X}Q_n + YQ_n$
(C) $\bar{X}Q_n + \bar{Y}Q_n$ (D) $\bar{X}\bar{Q}_n + YQ_n$

9. Consider reading a block from a disk using DMA technique. Then which of the following factors will limit the rate of transfer?
(i) Limiting speed of I/O devices
(ii) Speed of bus
(iii) Too small internal buffering space
(A) (i), (ii) only (B) (ii), (iii) only
(C) (i), (iii) only (D) (i), (ii), (iii)

10. If a normal processor memory Read (RD) and write (WR) control outputs are connected to I/O interface adapters, then which type of I/O technique is used?
(A) Memory mapped
(B) Isolated I/O
(C) Both Memory mapped and Isolated I/O
(D) Interrupt-driven I/O

11. What is the signed decimal equivalent of the 2's complement number: 00001111
(A) –15 (B) –240
(C) +15 (D) +241

12. Right arithmetic shift of ones complement of –6 is (in 8-bits)
(A) 00000011 (B) 01000011
(C) 01111100 (D) 11111100

13. LRU is an effective cache replacement policy primarily because

(A) Programs exhibit locality of reference.
(B) Programs usually have small working sets.
(C) Programs read data much more frequently than write data.
(D) Program can generate addresses that collide in the cache.

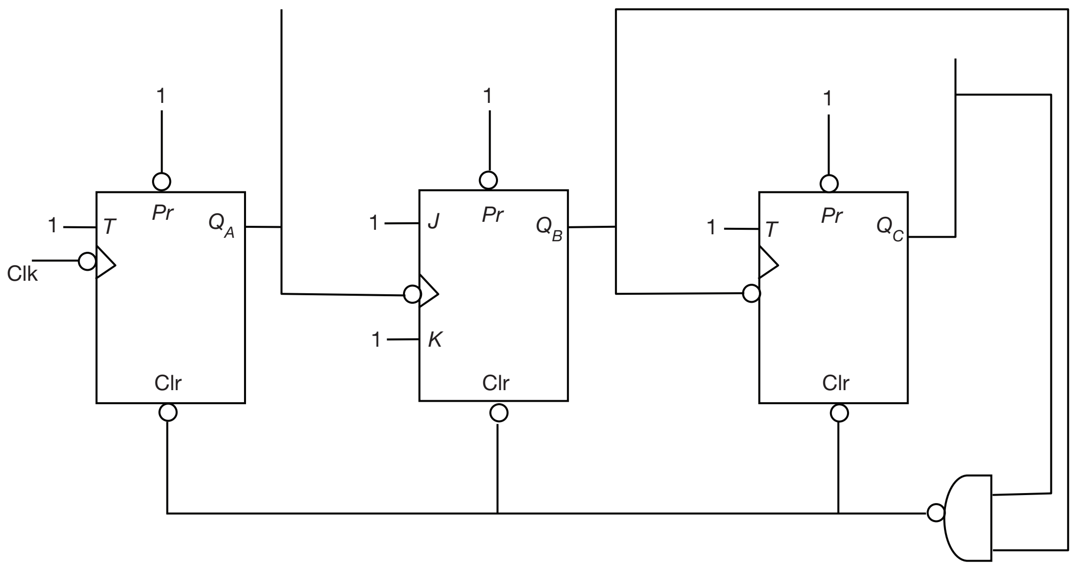
14. "The purpose of cache memory is to increase the size of main memory". This statement is

(A) Always true (B) Always False
(C) Sometimes true (D) Sometimes false

15. A memory has 2^{36} addressable locations. What is the smallest width in bits that the address can be, while still being able to address all 2^{36} locations?

(A) 36-bits (B) 72-bits
(C) 18-bits (D) 9-bits

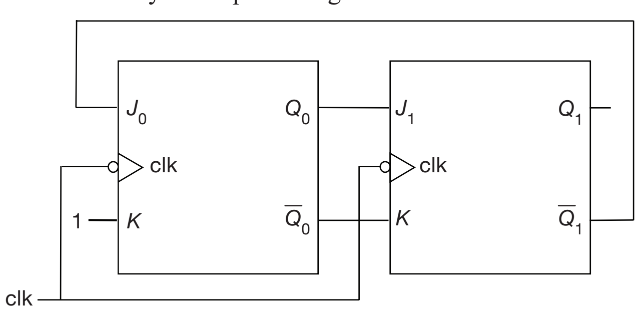
16.



A counter formed with T, JK flip flops, as shown above, preset (Pr), clear (clr) are active low, asynchronous inputs, T, J, K are synchronous inputs. The modulus of the counter is:

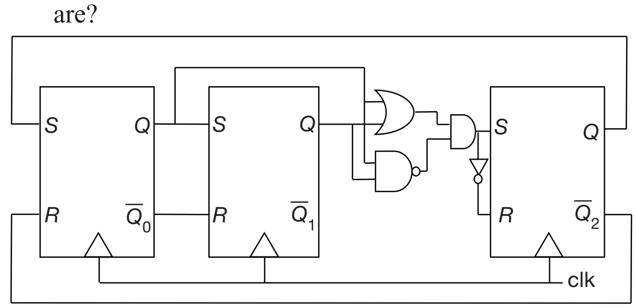
(A) 4
(B) 5
(C) 6
(D) 7

17. The flip flops used in this circuit are master-slave JK flip flops. If the counter is initially at reset state after how many clock pulses it gets reset?



(A) 2 (B) 3
(C) 4 (D) 1

18. The counter shown above has initial state $Q_2\ Q_1\ Q_0$ = 111(7), then the next states of ($Q_2\ Q_1\ Q_0$) (in decimal) are?



(A) 7, 6, 2, 1, 4, 3, 5 (B) 7, 3, 5, 2, 6, 1, 4
(C) 7, 3, 2, 4, 1, 6, 5 (D) 7, 5, 1, 4, 2, 3, 6

19. The max term expression of a four variable even function is?

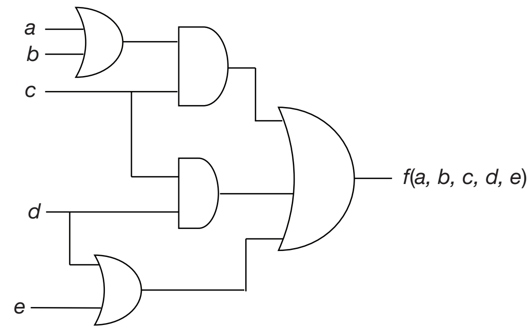
(A) πM (0, 2, 4, 6, 8, 10, 12, 14)
(B) πM(1, 3, 5, 7, 9, 11, 13, 15)
(C) πM (0, 3, 5, 6, 9, 10, 12, 15)
(D) πM (1, 2, 4, 7, 8, 11, 13, 14)

20. If $(3.5)_{\text{base } 6} + (2.3)_{\text{base } 6} = (X)_{\text{base } 6}$ then the value of X is:

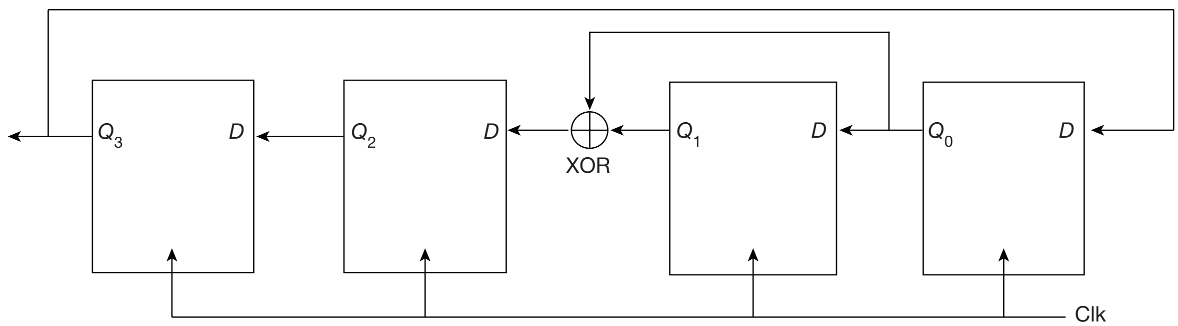
(A) 5.8 (B) 10.2
(C) 6.2 (D) 5.6

21. If the following circuit is converted to all-NAND network, then How many number of NAND gates are required? (inverted inputs are available)

(A) 3 (B) 4
(C) 5 (D) 6

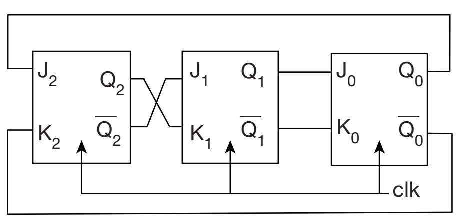


22. A 4-bit shift register is connected as shown with initial states $Q_3\ Q_2\ Q_1\ Q_0$ = 0100. What is state $Q_3\ Q_2\ Q_1\ Q_0$ after 5 clock pulses?



(A) 0111 (B) 1100
(C) 1111 (D) 1001

23.



For the counter shown above the initial state is $Q_2Q_1Q_0$ is 101, what is state after 5 clock pulses?

(A) 111 (B) 011
(C) 100 (D) 000

24. A cache access requires one clock cycle and handling cache miss stalls the processor for an additional 4 clock cycles. Which of the following cache hit rates comes closest to achieve an average memory access of 2 cycles?

(A) 75% (B) 80%
(C) 85% (D) 90%

25. Consider a byte-addressable system with 16-bit addresses associated a cache, which has a two-way set-associative write-back cache with perfect LRU replacement. The Tag store requires a total of 4608 bits of storage. What is the block size of the cache?

(A) 4 B (B) 5 B
(C) 32 B (D) Data insufficient

26. Consider a system employing interrupt-driven I/O for a particular device that transfers data at an average of 10 KB/sec on a continuous basis. Assume that interrupt processing takes about 200 μs. What fraction of processor time is consumed by this I/O device if it interrupts for every byte?

(A) 0.2 (B) 2
(C) 20 (D) 200

27. Consider a program which takes 200 seconds to execute. Of his time, 30% is used for multiplication, 40% for memory access instructions and 30% for other tasks. To enhance the performance, make multiply instructions run four times faster than before. What will be the speed up be if you improve the multiply instruction time?

(A) 0.29 (B) 0.71
(C) 1.29 (D) 1.71

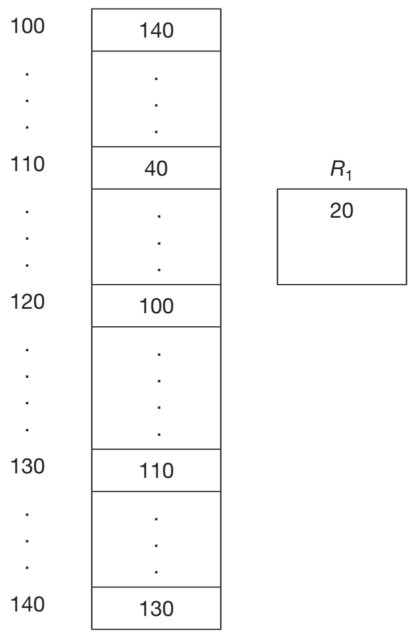
28. Consider the following code sequence (First operand is destination):

LOOP: LOAD R_0, 0(R_{10})
MUL R_0, R_0, R_2
LOAD R_4, 0(R_{11})
ADD R_0, R_0, R_4
STORE R_0, 0(R_{11})
SUB R_{10}, R_{10}, #8
SUB R_{11}, R_{11}, #8
BNEZ R_{10}, LOOP

How many 'WAW' hazards are there in given code?

(A) 8 (B) 5
(C) 3 (D) 0

29. Suppose we have an instruction 'LOAD 100'.
The memory and register R_1 contain the values as given below:

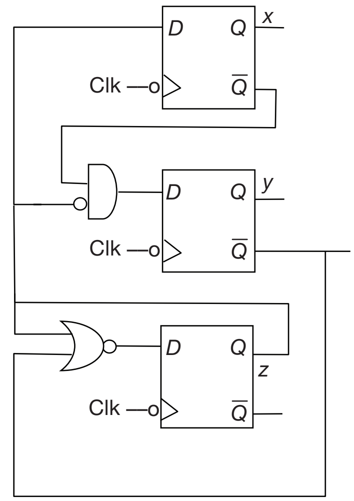


Assuming R_1 is implied in the indexed addressing mode, what will be the actual value loaded into accumulator in immediate, direct, indirect and indexed mode respectively:
(A) 140, 140, 130, 100 (B) 100, 140, 130, 100
(C) 140, 100, 130, 20 (D) –, 100, 140, 120

30. How many bits would you need, to address a $2G \times 32$ memory, if the memory is byte-addressable and word addressable respectively?
(A) 36, 31 (B) 31, 31
(C) 31, 36 (D) 36, 36

31. Suppose a computer using direct mapped cache has 2^{20} words of main memory and a cache of 32 blocks, where each cache block contains 16 words. To which cache block will the memory reference $(0DB63)_{16}$ map?
(A) 3 (B) 22
(C) 32 (D) 10

Common Data for Questions 32 and 33:
Consider the following circuit involving three D-type flip flops used in a certain type of counter configuration.



32. If at some instance prior to the occurrence of the clock edge x, y and z have a value 0, 1, and 1, what shall be the value of xyz after the clock edge?
(A) 000 (B) 100
(C) 010 (D) 101

33. If all the flip flops were reset to 0 at power on, what is the total number of distinct outputs (states) represented by xyz generated by the counter?
(A) 4 (B) 5
(C) 6 (D) 7

Common Data for Questions 34 and 35:
A processor requires 2000 cycles to perform a context switch and start an interrupt handler or 1000 cycles to poll an I/O device. An I/O device attached to that processor makes 100 requests per second, each of which takes 10,000 cycles to resolve once the handler has been started. By default, the processor polls every 0.5 ms if it is not using interrupts.

34. How many cycles per second does the CPU spend handling I/O from the device if interrupts are used?
(A) 1400000 (B) 1200000
(C) 14000 (D) 12000

35. How many cycles per second are spent on I/O if polling is used?
(A) 1000000 (B) 2000000
(C) 3000000 (D) 5000000

Hints and Explanations

1. The characteristic equation of *SR* flip flop is:

$Q_{n+1} = S + \bar{R}$
Q_n

Given (from circuit) $S = A \cdot \bar{Q}_n, R = B \cdot Q_n$

$Q_{n+1} = A\bar{Q}_n + \bar{B} \cdot \bar{Q}_n$
Q_n

$= A\bar{Q}_n + (\bar{B} + \bar{Q}_n)Q_n$

$Q_{n+1} = A\bar{Q}_n + \bar{B}$
Q_n

The equation is like JK flip flop equation.

(JK equation $Q_{n+1} = J\bar{Q}_n + \bar{K}Q_n$)

So it works like *T* flip flop if $A = B$. Choice (D)

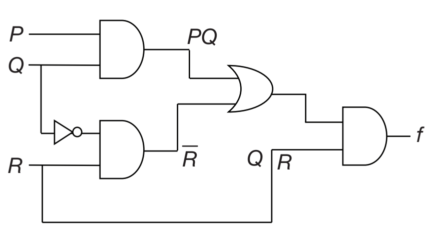
2. If $a \leq b$ then

a	b	$a^1 + b$	ab^1
0	0	1	0
0	1	1	0
1	1	1	0

($ab = 10$ is not valid condition for $a \leq b$)
We can observe that $a^1 \geq b^1$, so only (*P*) $a^1 + b = 1$, (*R*) $ab^1 = 0$ are true. Choice (B)

3. From given $a = (b + c)(b^1 + c^1)$
$= bc^1 + b^1c$
$= b \oplus c$
EXOR with *c* both sides
$a \oplus c = b \oplus c \oplus c = b \oplus 0 = b$
So, $b = a \oplus c = a^1c + ac^1$ or $(a + c)(a^1 + c^1)$.
Choice (B)

4.



$f = (PQ + \bar{Q}R)R = PQR + \bar{Q}R$

$= (PQ + \bar{Q})R = (P + \bar{Q})R$

$= PR + \bar{Q}R$ Choice (C)

5. Given circuit is Demultiplexer

Output equation are $Y_0 = I\,\bar{S}_1\,\bar{S}_0$

$Y_1 = I\,\bar{S}_1\,S_0$

$Y_2 = I\,S_1\,\bar{S}_0$

$Y_3 = I\,S_1\,S_0$

$F(a, b) = \overline{\overline{Y_0} \cdot \overline{Y}_3} = Y_0 + Y_3 = 1 \cdot a^1b^1 + 1 \cdot ab$

$= a^1\,b^1 + ab = (a^1 + ab)(b^1 + ab)$

By applying $x + yz = (x + y)(x + z) = (a^1 + b)(a + b^1)$
Choice (B)

6. If the output of the circuit is *F* then $F(x, y, z) = \Sigma(1, 2, 4) + d(6, 7)$ in the given range 000 to 101, only for inputs 001, 010, 100 output is 1 (min terms) 110, 111 are unused combinations (don't cares)

x \ yz	00	01	11	10
0		1		1
1	1		X	x

$F(x, y, z) = xz^1 + yz^1 + x^1y^1z$
$= (x + y)z^1 + x^1y^1z$
$= (x^1y^1)^1z^1 + (x^1y^1)z = (x + y)z^1 + (x + y)^1z$
$= x^1\,y^1 \odot z = (x + y) \oplus z$ Choice (D)

7. $f = b + cd + ade$
a b c d e
b = - 1 - - - → 16 min terms (2^4)
cd = - - 1 1 - → 8 min terms (2^3)
in these 8 terms, 4 terms will have $b = 1$,
so $8 - 4 = 4$ terms
ade = 1 - - 1 1 → 4 min terms (2^2)
these 4 terms are already present in first 16 terms so no need to count them. Total = 16 + 4 = 20 Choice (A)

8. Given functional table is same as JK flipflop with $J = \bar{X}, K = \bar{Y}$, so $Q_{n+1} = \bar{X}\bar{Q}_n + Y$
Q_n Choice (D)

9. Choice (D)

10. Choice (A)

11. Given number: 00001111. The sign is '0', so the number is positive.
∴ Decimal equivalent = +15. Choice (C)

12.

–6	=	1	0	0	0	0	1	1	0

(SM)

In one's complement,
– 6 = 11111001
Arithmetic Right shift of –6 = 11111100
(sign bit must be same). Choice (D)

13. LRU replaces locations that have the lowest probability of being accessed in the cache. Choice (A)

14. Cache memory doesn't extend the size of main memory but useful in faster program execution. Cache memory contains only some replica of main memory. Choice (B)

15. Choice (A)

16. Given circuit is an Asynchronous counter (ripple counter). All flip flops are in toggle mode.
Q_A is LSB (clk input is connected to Q_A)
Negative edge Clk is connected from *Q*, so it works as UP counter.

$Q_C\, Q_B\, Q_A$ is the sequence, UP counter.
The NAND gate connected from $Q_B\, Q_C$
i.e., whenever output $Q_C\, Q_B\, Q_A$ becomes 110 or 111, the NAND gate output is zero.
i.e., the same zero applied to the active low asynchronous inputs pr, clr of Q_A, QB, Q_C.
so initial state is 001

Clk	Q_C	Q_B	Q_A
0	0	0	1
1	0	1	0
2	0	1	1
3	1	0	0
4	1	0	1
5	0	0	1

So total 5 different states.
∴ Given circuit is mod-5 counter. Choice (B)

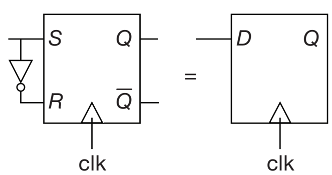
17. Master slave flip flop also works like normal flip flop only, to eliminate race around condition in JK latch, we go for JK master slave flip flop.

From the circuit $J_0 = \bar{Q}_1, K_0 = 1, J_1 = Q_0, K_1 = \bar{Q}_0$

clk	Q_1 Q_0	$J_1 = Q_0$	$K_1 = \bar{Q}_0$	$J_0 = \bar{Q}_1$	$K_0 = 1$
0	0 0	0	1	1	1
1	0 1	1	0	1	1
2	1 0	0	1	0	1
3	0 0				

∴ 3 clk pulses required to reset again. Choice (B)

18.



We can observe that SR connected in D flip flop mode, S, R are connected with normal (Q), complemented ($\bar{Q}$) output forms.

We can draw the circuit as follows
From given circuit $D_0 = Q_2$, $D_1 = Q_0$

$$D_2 = (Q_1 + Q_0)(\overline{Q_1 \cdot Q_0}) = (Q_1 + Q_0)(\bar{Q}_1 + \bar{Q}_0) = Q_1 \oplus Q_0$$

clk	Q_2 Q_1 Q_0	$D_2 = Q_1 \oplus Q_0$	$D_1 = Q_0$	$D_0 = Q_2$
0	1 1 1	0	1	1
1	0 1 1	0	1	0
2	0 1 0	1	0	0
3	1 0 0	0	0	1
4	0 0 1	1	1	0
5	1 1 0	1	0	1
6	1 0 1	1	1	1
7	1 1 1			

∴ The state sequences of given circuit are 7, 3, 2, 4, 1, 6, 5, 7 . . . Choice (C)

19. Even function is a Boolean function, which will be equal to 1, if the input variables have an even number of 0's.

(odd function is a Boolean function for which output is 1, for input combinations with odd number of 1'*s*)

So for 4 variables, even number of zeroes occur for input combinations 0000, 0011, 0101, 0110, 1001, 1010, 1100, 1111

For these combinations, even function output is 1.

So remaining terms are max terms.

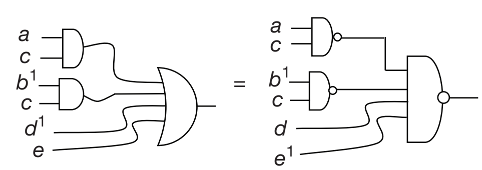
So $f_{\text{even}} = \prod M(1, 2, 4, 7, 8, 11, 13, 14)$

Choice (D)

20. 3.5
$+\underline{2.3}$
?
$5 + 3 = 8$
$(8)_{10} = (12)_6$, so result is 2 and carry is 1.
1
3.5
$\underline{+2.3}$
?.2
$1 + 3 + 2 = 6$
$(6)_{10} = (10)_6$, so result is 0 and carry is 1
3.5
$+\underline{2.3}$
10.2 Choice (B)

21. Given function has to be in SOP form, so it can be implemented by AND-OR gates, same as NAND-NAND gates

$f(a, b, c, d, e) = (a + b^1)c + cd^1 + (d^1 + e)$
$= ac + b^1c + cd^1 + d^1 + e$



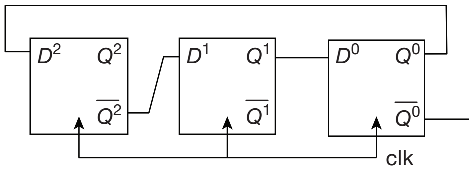
$= ac + b^1\, c + d^1 + e$ Choice (A)

22.

	Present state				Q_2	$Q_1 \oplus Q_0$	Q_0	Q_3
Clk	Q_3	Q_2	Q_1	Q_0	D_3	D_2	D_1	D_0
0	0	1	0	0	1	0	0	0
1	1	0	0	0	0	0	0	1
2	0	0	0	1	0	1	1	0
3	0	1	1	0	1	1	0	0
4	1	1	0	0	1	0	0	1
5	1	0	0	1	0	1	1	1
6	0	1	1	1				

Choice (D)

23. Given circuit can be drawn as



As JK flip flop is used in Data mode $(J = \bar{K})$

Clk	Q_2 Q_1 Q_0
0	1 0 1
1	1 0 0
2	0 0 0
3	0 1 0
4	0 1 1
5	1 1 1

Choice (A)

24. Average access time = 2
Cache access time = 1
Time to handle miss = 5
Let cache hit rate = x
$2 = 1 \times x + 5(1 - x)$
$\Rightarrow \quad x + 5 - 5x = 2$
$\Rightarrow \quad -4x = -3$
$\Rightarrow \quad x = \frac{3}{4} = 0.75$
$\therefore$ Hit ratio = 75%. Choice (A)

25. In 2-way set-associative cache,
t(Tag) + s(Set) + w(Word) = 16
For LRU, use 1-bit per set.
For Valid bit, Dirty bit use 1 bit per block for each.
Let tag has t-bits per block.
Number of sets = 2^s
Number of blocks = 2×2^s
Tag store size = $2^s + 2 \times 2^s \times (2 + t)$
Given tag store size = 4608 bits
$2^s + 4 \times 2^s + 2^{s+1} \times t = 4608$
$\Rightarrow \quad 5 \times 2^s + t \times 2^{s+1} = 2^{12} + 2^9$
$\Rightarrow \quad 2^s(2t + 5) = 2^9 \times 9$
$\Rightarrow \quad s = 9, t = 2 \Rightarrow w = 5$
$\therefore$ Block size = 2^5 = 32 bytes. Choice (C)

26. The device generates 10000 interrupts per second i.e., one for every 100 μs.
Each interrupt requires 200 μs, then fraction of processor time consumed $= \frac{200}{100} = 2.$ Choice (B)

27. Speed up $= \dfrac{1}{(1 - \text{fraction}) + \dfrac{\text{Fraction}_{\text{enh}}}{\text{Speedup}_{\text{enh}}}}$

$= \dfrac{1}{(1 - 0.3) + \dfrac{0.3}{4}}$ Choice (C)

28. There are three WAW hazards.
(1) LOAD R_0, $0(R_{10})$
MUL R_0, R_0, R_2
(2) MUL R_0, R_0, R_2
ADD R_0, R_0, R_4
(3) LOAD R_0, $0(R_{10})$
ADD R_0, R_0, R_4. Choice (C)

29. Immediate: Data is present in instruction i.e., $AC = 100$
Direct: Instruction contains effective address of operand i.e., $AC = M[100] = 140$
Indirect: Instruction contains address of address of operand.
i.e., $AC = M[M[100]] = M[140] = 130$
Indexed: Address part of instruction is added with IR.
i.e., $AC = M[IR + 100] = M[20 + 100] = M[120] = 100.$
Choice (B)

30. Memory capacity : $2G \times 32 = 2^{31} \times 2^5$
Byte Addressable requires 36-bits for an address.
Word addressable requires 31-bits. Choice (A)

31. Main memory = 2^{20}
Number of blocks in cache = 32
Block size = 16 words

Tag	Line	Word
11	5	4

Given address $(0DB63)_{16}$

	0000 1101101	10110	0011
=	Tag	line	word

Line = 10110 = $(22)_{10}$. Choice (B)

32. From the given circuit, inputs are
As all flip flops are D flip flops, output (as of input) will be same as D-state.
Given initially $xyz = 011$.
So $D_x = 1, D_y = 0, D_z = 0$
So next state $xyz = 100$. Choice (B)

33.

Clk	x	y	z	$D_x = z$	$D_y = \overline{xz}$	$D_z = \bar{z}y$
0	0	0	0	0	1	0
1	0	1	0	0	1	1
2	0	1	1	1	0	0
3	1	0	0	0	0	0
4	0	0	0			

After 4 clk pulses again come back to original state (000) so number of states are 4. Choice (A)

34. I/O device generates 100 requests.
Each request requires an interrupt.
The time taken for one request is
= 2000 + 10000 + 2000 = 14000 (to start handler, execute handler, switch to original program).
Total there are 100 requests so cycles required
= 14000 × 100 = 1400000. Choice (A)

35. The processor polls for every 0.5 ms. In one second there will be $\frac{1}{0.5\times10^{-3}}$ polls i.e., 2000 times.

Each poll requires 1000 cycles.

So it requires 2000000 cycles.

There are 100 requests, each requires 10000 cycles, total 1000000 cycles to complete.

$\therefore$ Total time spent on I/O each second
= 2000000 + 1000000 = 3000000. Choice (C)

Chapter 1

ER Model and Relational Model

LEARNING OBJECTIVES

- *NULL in tuples*
- *Inherent constraint*
- *Referential and entity integrity constraint*

Introduction

A database is a collection of related data. By data, we mean facts that can be recorded and that have implicit meaning.

Example: Consider the names, telephone numbers and addresses of the people. We can record this data in an indexed address book and store it as Excel file on a hard drive using a personal computer. This is a collection of related data with an implicit meaning and hence is a database.

A database management system (DBMS) is a collection of programs that enables users to create and maintain a database. The DBMS is a general-purpose software system that facilitates the processes of defining, constructing, manipulating and sharing databases among various users and applications.

1. Defining the database involves specifying the data types, structures, and constraints for the data to be stored in the database.
2. Constructing the database is the process of storing the data itself on some storage medium that is controlled by the DBMS
3. Manipulating a database includes such functions as querying the database to retrieve specific data, updating the database to reflect changes.
4. Sharing a database allows multiple users and programs to access the database concurrently.
5. Fundamental characteristics of the database approach is that it provides some level of data abstraction by hiding details of data storage that are not needed by users.

Data Model

A data model is a collection of concepts that can be used to describe the structure of a database. It provides the necessary means to achieve abstraction.

Schemas

In any data model, it is important to distinguish between the description of the database and the database itself. The description of a database is called the *database schema*, which is specified during database design and is not expected to change frequently.

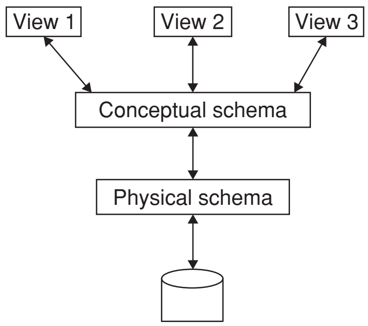
The actual data in a database may change frequently, for example the student database changes every time we add a student or enter a new grade for a student. The data in the database at a particular moment in time is called a *database state* or *snapshot*. It is also called the *current set of occurrences* or *instances in the database*.

The distinction between database schema and database state is very important. When we define a new database, we specify its database schema only to the DBMS. At this point, the corresponding database state is the empty state with no data. We get the initial state of the database when the database is first loaded with the initial data. The DBMS stores the description of the schema constructs and constraints, also called the *metadata* in the DBMS catalog so that DBMS software can refer to the schema whenever it needs. The schema is sometimes called the *intension*, and the database state an *extension* of the schema.

Three-schema Architecture

The goal of the three-schema architecture is to separate the user applications and the physical database.

Levels of Abstraction



1. The external or view level includes a number of external schemas or user views. Each external schema describes the part of the database that a particular user group is interested in and hides the rest of the database.
2. The conceptual level has a conceptual schema, which describes the structure of the whole database for a community of users. The conceptual schema hides the details of physical storage structures and concentrates on describing entities, data types, relationships, user operations, and constraints.
3. The internal level has an internal schema, which describes the physical storage structures of the database. It describes the complete details of data storage and access paths for the database.

ER Model

Entity relationship model is a popular high-level conceptual data model. This model and its variations are used for the conceptual design of database applications, and many database design tools employ its concepts. ER model describes data as entities, relationships and attributes. The basic object that the ER model represents is an entity.

Entity

It is an object that exists and is distinguishable from other objects
(or)
Entity is a "thing" in the real world with an independent existence.
(or)
An entity is something that has a distinct, separate existence, although it need not be a material existence. In particular, abstractions and legal functions are usually regarded as entities. In general, there is no presumption that an entity is animate.

1. An object with a physical existence
   Example: A particular person, car, house, employee.
2. An object with a conceptual existence
   Example: A company, a job, a university course. Each entity has attributes, the particular properties that describe it.
   Example: An employee entity can be described by employee's name, age, address, salary and job.

Entity Set

Set of entities of same type that shares the same properties.

Example: All persons, all companies etc.

Example: Entity sets of customer and loan

Table 1 *Customer Entity Set*

Customer-id	Cust-name	Cust-street	City
C-143	John	MG Road	Sec.bad
C-174	Mary	SP Road	Hyd.bad
C-183	Tony	KD Road	Sec.bad
C-192	Satya	SG Road	Eluru

Table 2 *Loan Entity Set*

Loan-no	Amount
L-30	$3000
L-31	$4000
L-32	$3500
L-33	$4500
L-34	$5000

An entity is represented by a set of attributes and by a descriptive properties possessed by all members of an entity set.

Types of Attributes

1. Simple versus composite
2. Single valued versus multivalued
3. Stored versus derived.

*Composite attribute***:** Composite attributes can be divided into smaller subparts, which represent more basic attribute that has their own meaning (Figure 1).

Example: A common example is Address, it can be broken down into a number of subparts such as street address, city, postal code; street address is further broken down into Number, street Name and Apartment number.

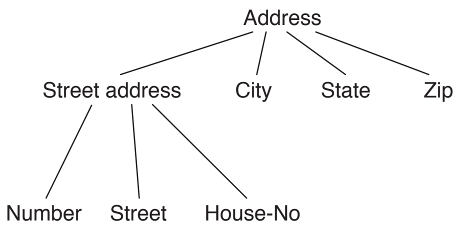


Figure 1 A hierarchy of composite attributes.

Street address is a composite attribute. Attributes that are not divisible are called simple (or) atomic attributes.

Single-valued versus multivalued attributes: Most attributes have a single value for a particular entity, such attributes are called *single-valued attribute*.

Example: Age is a single-valued attribute

Multivalued attributes: An attribute can have a set of values for the same entity.

Example: College degrees attribute for a person
Example: Name is also a multivalued attribute (Figure 2).

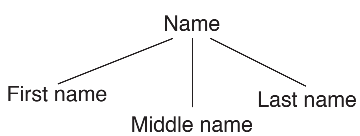

Figure 2 Multivalued attribute.

Stored versus derived attributes: Two (or) more attribute values are related.

Example: Age can be derived from a person's date of birth. The age attribute is called derived attribute and is said to be derivable from the DOB attribute, which is called a stored attribute.

Domain: The set of permitted values for each attribute.

Example: A person's age must be in the domain {0-130}

Relationship Sets

A relationship is an association among several entities. Relationship sets that involve two entity sets are binary. Generally, most relationships in databases are binary. Relationship sets may involve more than two entity sets.

Example: Employee of a bank may have responsibilities at multiple braches, with different jobs at different branches, then there is a ternary relation between employee, job and branch.

Mapping Cardinality

For a binary relationship set, mapping cardinality must be:

1. One-to-one
2. One-to-many
3. Many-to-one
4. Many-to-many

One-to-one: An entity in *A* is associated with at most one entity in *B* and an entity in *B* is associated with at most one entity in *A* (Figure 3).

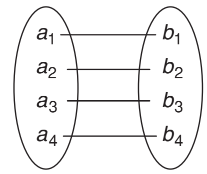

Figure 3 One-to-one relationship set.

One-to-many: An entity in *A* is associated with any number of entities in *B*. But an entity in *B* is associated with at most one entity in *A* (Figure 4).

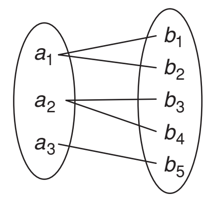

Figure 4 One-to-many relationship set.

Many-to-one: An entity in *A* is associated with at most one entity in *B*. But an entity in *B* can be associated with any number of entities in *A* (Figure 5).

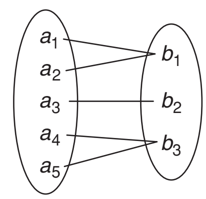

Figure 5 Many-to-one relationship set.

Many-to-many: An entity in *A* is associated with any number of entities in *B*. But an entity in *B* can be associated with any number of entities in *A* (Figure 6).

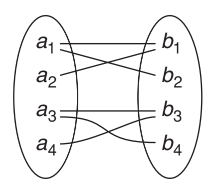

Figure 6 Many-to-many relationship set.

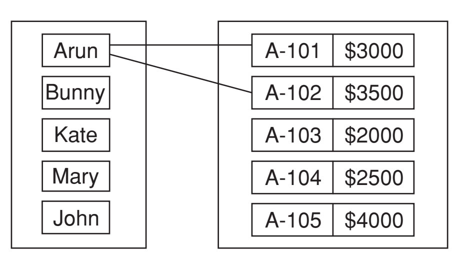
Example: One customer can have multiple accounts
Customer(c-Name) (Acc. no, Amount)

Table 3 *Example of One-to-many Relationship Set*



In Table 3, many-to-one relationship is not possible.

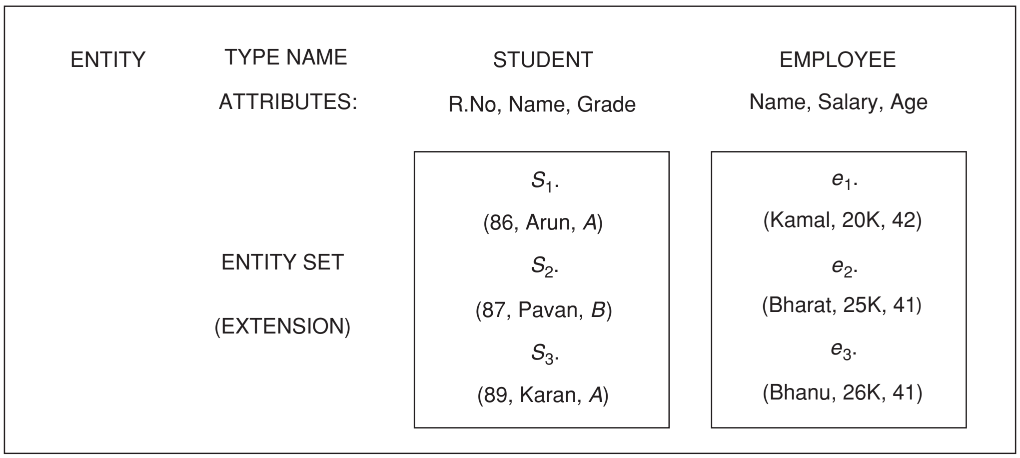
Complex Attributes

Composite and multivalued attributes can be nested in an arbitrary way. We can represent arbitrary nesting by grouping components of a composite attribute between parentheses () and separating the components with commas, and by displaying multivalued attributes between braces { }. Such attributes are called complex attributes.

Example: A person can have more than one residence and each residence can have multiple phones, an attribute AddressPhone for a person can be specified as shown below. {AddressPhone ({Phone (Areacode, phoneNumber)}, Address (StreetAddress (StreetNumber, streetName, ApartmentNumber), city, state, zip))}

Entity types, entity sets and value sets

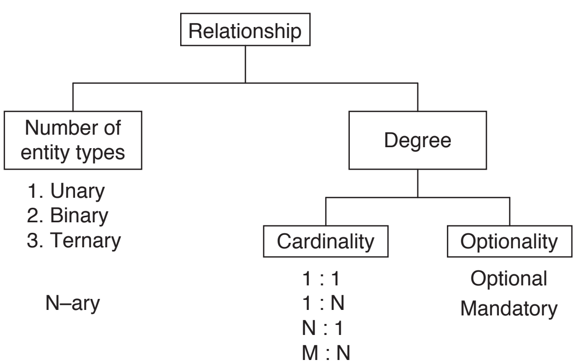
An entity type defines a collection of entities that have the same attributes. Each entity type in the database is described by its name and attribute. The following figure shows two entity types, named STUDENT and EMPLOYEE and a list of attributes for each



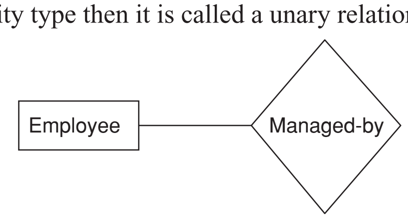
The collection of all entities of a particular entity type in the database at any point in time is called an *entity set*.

Types of relations

1. Unary relation.
2. Binary relation.
3. Ternary relation.
4. Quadnary relation.
5. N-ary relation



Unary relation If a relationship type is between entities in a single entity type then it is called a unary relationship type.

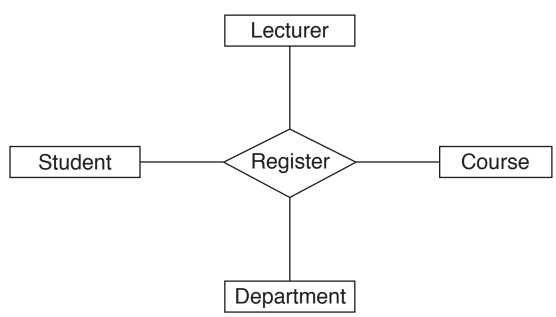


In employee entity, we will have all the employees including 'manager', this relation indicates, employees are managed by manager.

Binary relation If a relationship type is between entities in one type and entities in another type then it is called a *binary relation*, because two entity types are involved in the relation.

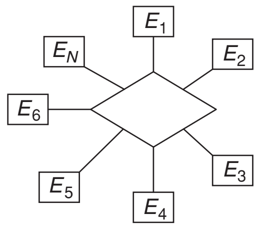
The above relation indicates that customers purchased product (or) products are purchased by customers.

Quadnary relation If a relationship type is among entities of four different types, then it is called *quadnary relation*.



In the above ER-diagram, any two entities can have a relation.

N-ary relation 'N' number of entities will participate in a relation, and each entity can have a relation with all the other entities.

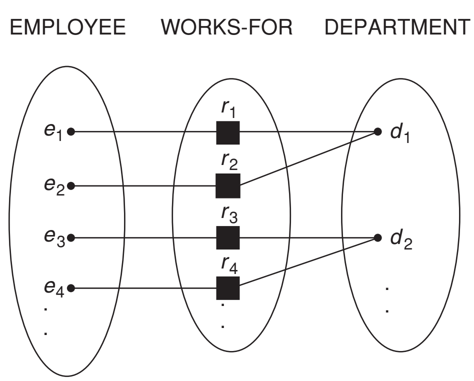


Cardinality Ratio and Participation Constraints

The cardinality ratio for a binary relationship specifies the maximum number of relationship instances that an entity can participate in

1. The participation constraint specifies whether the existence of an entity depends on its being related to another entity via the relationship type. This constraint specifies the minimum number of relationship instances that each entity can participate in, and is some times called the *minimum cardinality constraint*.
2. There are two types of participation constraints:
   a. Total participation
   b. Partial participation

Example: If a company policy states that every employee must work for a department, then an employee entity can exist only if it participates (or) works for at least one department.



Every entity in the EMPLOYEE set must be related to a DEPARTMENT entity via WORK-FOR. Total participation is also called *existence dependency*. If we do not expect every employee to manage a department, so the participation of EMPLOYEE in the relationship type is partial, means not necessarily all employees' entities are related to some department entity.

Cardinality ratio and participation constraints are taken together as the structural constraints of a relationship type. In ER diagrams, total participation is displayed as a double line connecting the participating entity type to the relationship, whereas partial participation is represented by a single line.

ER Diagrams (Figure 7 and 8)

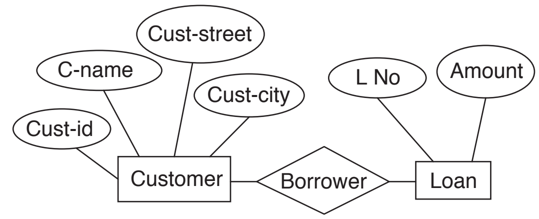


Figure 7 ER diagram.

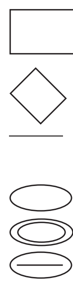
Notations:



→ Represents entity
→ Represents relationship sets
→ Represents links between attributes to entity sets and entity sets to relationship sets
→ Represents attributes
→ Represents multivalued attributes
→ Represents primary key attribute

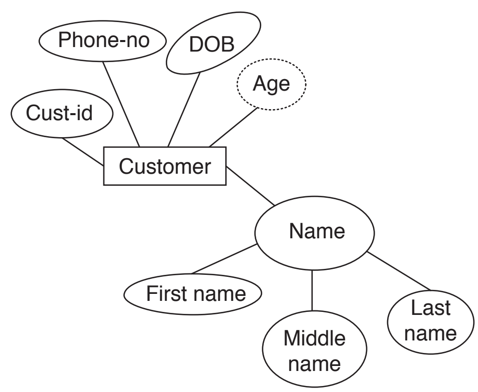


Figure 8 ER diagram.

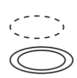
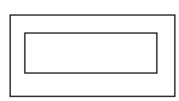
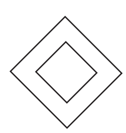


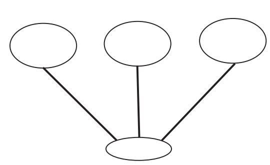
→ Derived attribute
→ Multivalued attribute



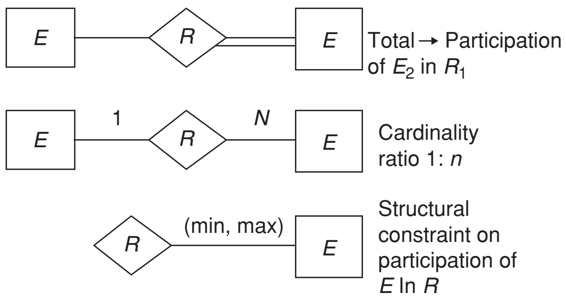
→ Weak entity



→ Weak entity set relation



→ Composite attribute



Cardinality Constraints

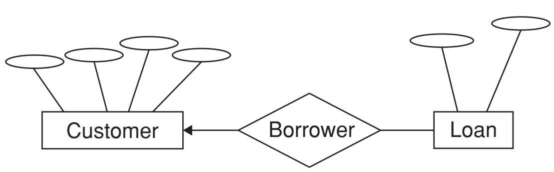
One-to-one

Each entity of one entity set is related to at most one entity of the other set. Only one matching record exists between two tables.

Example: Assume each owner is allowed to have only one dog and each dog must belong to one owner. The own relationship between dog and owner is one-to-one. One-to-one relationships can often combine the data into one table.

Examples:

1. One birdfeeder is located in one place in the yard.
2. One state has one governor.
3. One yard has one address.
4. One patient has one phone number.
2. One student has one ID.



One customer is associated to one loan via borrower

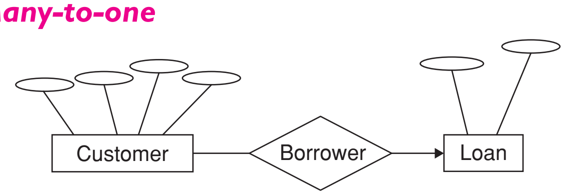
One-to-many

Examples:

1. One birdfeeder is visited by many birds.
2. One student can have many degrees.
3. One Book can be written by many authors.
4. One yard contains many bird feeders.
5. One patient has many prescriptions.

In the one-to-many relationship, a loan is associated with one customer via borrower.

Many-to-one

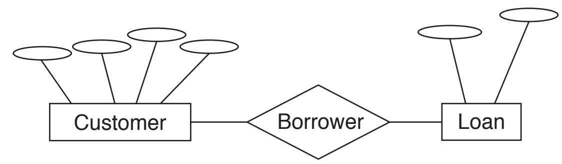


A customer is associated with at most one loan via borrower.

Many-to-many

Examples:

1. Many students are taught by many teachers.
2. Many patients are treated by many doctors.
3. Many medications are taken by many patients.
4. Many customers buy many products.
5. Many books are written by many authors.



Customer is associated with several loans and loan is associated with several customers.

ER Diagram with a Ternary Relationship

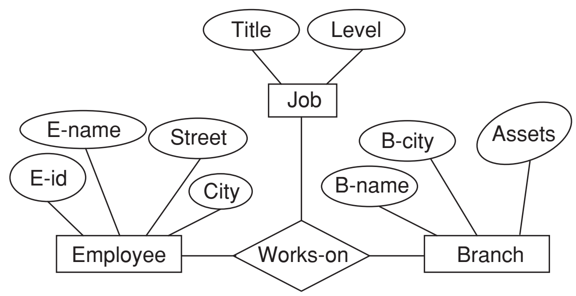


Figure 9 ER diagram with a ternary relationship.

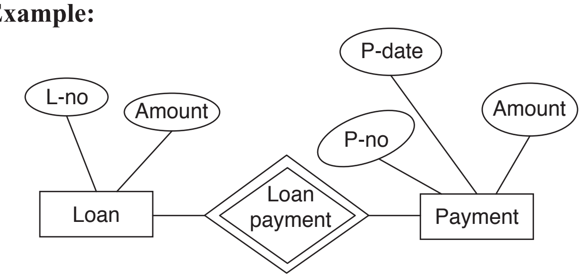
Weak Entity Set

An entity set that does not have a primary key is called *weak entity set*.

Weak entity set is represented by → 
Underline the primary key of a weak entity with a dashed line.

Example:



Relational Database

Relational Model

The relational model represents the database as a collection of relations. When a relation is thought of as a table of values, each row in the table represents a collection of related data values. Each row in the table represents a fact that typically corresponds to a real-world entity. The table name and

column names are used to help in interpreting the meaning of the values in each row.

In formal relational model terminology, a row is called a *tuple*, a column header is called an *attribute*, and the table is called a *relation*.

Domain

A domain is a set of atomic values. A common method of specifying a domain is to specify a data type from which the data values forming the domain are drawn. It is also useful to specify a name for the domain, to help in interpreting its values

Example:

1. *Set of telephone numbers*: The set of valid numbers in a particular country.
2. *Employee id numbers*: The set of valid employee numbers in a company.
3. *Names*: The set of character strings that represent names of persons.
4. *Grade-point average*: Possible values of computed grade point averages, each must be real (floating point) number between 0 and 4
5. *Research department names*: The set of research department names in a specialization, such as computer science, chemistry and applied mathematics.
6. *Research department codes*: The set of Research department codes, such as CS, CHE, AM.

The preceding is called *logical definitions of domains*. The data type for research department names is set of character strings that represent valid department names. A domain is thus given a name, data type, and format. Additional information for interpreting the values of a domain can also be given, for example a numeric domain such as person weights should have the units of measurements, such as kilograms or pounds.

1. The relational model is often described as having the following three aspects:
   - *Structural aspect*: The data in the database is perceived by the user as tables.
   - *Integrity aspect*: Those tables has to satisfy certain integrity constraints.
   - *Manipulative aspect*: The operators available to the user for manipulating those tables, for purposes of data retrieval, these operators derive tables form tables, the most important operators are 'SELECT', 'PROJECT' and JOIN.

Relation Schema

A relation schema 'R' denoted by $R(A_1, A_2, \ldots A_n)$ is made up of a relation name R and a list of attributes $A_1, A_2, \ldots A_n$. Each Attribute A_i is the name of role played by some domain D in the relation schema R. D is called the domain of A_i and is denoted by dom(A_i).

A relation schema is used to describe a relation and R is called the name of this relation. The degree of a relation is the number of attributes 'n' of its relation schema.

Example:

A relation schema of degree '7', which describes an employee is given below:

EMPLOYEE (Name, EId, HomePhone, Address, Office phone, Age, Salary)

Using the data type of each attribute, the definition is written as:

EMPLOYEE (Name: String, EId: INT, Homephone: INT, Address: String, OfficePhone: String, Age: Real, Salary: INT)

For this relation schema, EMPLOYEE is the name of the relation, which has '7' attributes.

2. A relation 'r' of the relation schema $R(A_1, A_2 \ldots A_n)$, also denoted by $r(R)$, is a set of n-tuples. $r = \{t_1, t_2 \ldots t_m\}$. Each n-tuple 't' is an ordered list of n values $t = <V_1, V_2 \ldots N_n>$, where each value V_i, $1 \le i \ldots n$, is an element of dom(A_i) or is a special null value.
3. The ith value in tuple t, which corresponds to the attribute A_i, is referred to as $t[A_i]$.
4. The following figure shows EMPLOYEE relation. Each type in a relation represents a particular employee entity. We display the relation as a table where each tuple is shown as a row and each attribute corresponds to a column header, indicating a role or interpretation of the values in that column. Null values represent attributes whose values are unknown or do not exist for some individual EMPLOYEE tuple.

Employee

Name	EId	Home Phone	Address	Office Phone	Age	Salary
Mahesh	30-01	870-223366	Warangal	NULL	35	40 k
Ramesh	30-02	040-226633	Hyderabad	NULL	36	40 k
Suresh	30-03	040-663322	Kolkata	040-331123	35	42 k
Dinesh	30-04	040-772299	Bangalore	040-321643	36	40 k

Fig: The attributes and tuples of a relation EMPLOYEE. The earlier definition of a relation can be restated as follows:
A relation $r(R)$ is a mathematical relation of degree 'n' on the domains dom(A_1), . . . , dom(A_n), which is a subset of the Cartesian product of the domains that define R:

$$r(R)\ C\ (\text{dom}(A_1) \times \text{dom}(A_2) \ldots \times \text{dom}(A_n))$$

Characteristics of Relations

There are certain characteristics that make a relation different from a file or a table.

Ordering of tuples in a relation: A relation is defined as a set of tuples. Tuples in a relation do not have any particular order. In a file, records are stored on disk in order. This ordering indicates first, second, i^{th}, and last records in the file. Similarly, when we display a relation as a table, the rows are displayed in a certain order.

Tuple ordering is not part of a relation definition, because a relation attempts to represent facts at a logical or abstract level. Many logical orders can be specified on a relation. Tuples in the EMPLOYEE relation could be logically ordered by values of Name or by EID or by Age or by some other attribute. When a relation is implemented as a file or displayed as a table, a particular ordering may be specified on the records of the file or the rows of the table.

NULL in Tuples

Each value in a tuple is an atomic value; that is, it is not divisible into components. Hence, composite and multivalued attributes are not allowed. This model is sometimes called the *flat relational model*. Multivalued attributes must be represented by separate relations, and composite attributes are represented only by their simple component attributes in the basic relational model.

NULLS are used to represent the values of attributes that may be unknown or may not apply to tuple. For example, some student tuples have null in their office phones because they do not have an office. In this case, the meaning behind NULL is not applicable. If a student has a NULL for home phone, it means either he/she does not have a home phone or he/she has one but we do not know it, in this case the meaning of NULL is 'Unknown'.

Relational Model Constraints

In a relational database, there will be many relations, and the tuples in those relations are related in various ways. There are many restrictions or constraints on the actual values in a database state.

Constraints on database can generally be divided into three main categories as follows:

1. Constraints that are inherent in the data model, we call them *inherent model-based constraints*.
2. Constraints that can be directly expressed in the schemes of the data model, by specifying them in the DDL (Data Definition Language). We call these *schema-based constraints*.
3. Constraints that cannot be directly expressed in the schemas of the data model, and they must be expressed and enforced by the application programs are *application-based constraints*.

Inherent Constraint

The constraint that a relation cannot have duplicate tuples is an *inherent constraint*. Another important category of constraints is data dependencies, which include 'functional dependencies' and 'multivalued dependencies'. They are used mainly for testing the 'goodness' of the design of a relational database and are utilized in a process called normalization.

Schema-based Constraints

1. Domain constraints
2. Key constraints
3. Constraints on nulls (Not null constraint)
4. Entity integrity constraints
5. Referential integrity constraints
6. Unique constraint
7. Check constraint

Domain constraints

Domain constraints specify that within each tuple, the value of each attribute 'X' must be an atomic value from the domain dom(X).

The data types associated with domains include standard numeric data types for integers

1. Short integer
2. Integer
3. Long integer
4. Real numbers
    - Float
    - Double-precision float
5. Characters
6. Booleans
7. Fixed-length strings
8. Variable-length strings
9. Date, time, time stamp
10. Money data types

Key constraints

A relation is a set of tuples. All elements of a set are distinct; hence, all tuples in a relation must also be distinct. This means no two tuples can have the same combination of values for all their attributes.

1. There are other subsets of attributes of a relation schema R with the property that no two tuples in any relation state 'r' of R should have the same combination of values of these attributes.

   Suppose that we denote one subset of attributes by 'SK', then for two distinct tuples t_1 and t_2 in a relation state 'r' of R, we have the following constraint:

$$t_1[\text{SK}] = t_2[\text{SK}]$$

2. Any such set of attributes SK is called a *super key* of the relation schema *R*.

   SK specifies a uniqueness constraint that no two distinct tuples in any state *r* or *R* can have the same value for SK.
3. Every relation has at least one default super key, the set of all its attributes. *A* key, '*K*' of a relation schema *R* is a super key of *R* with the additional property that removing any attributes '*X*' from *K* leaves a set of attributes *K*' that is not a super key of *R* any more.

A key satisfies the following two constraints:

1. Two distinct tuples in any state of the relation cannot have identical values for all the attributes in the key.
2. A super key from which we cannot remove any attributes and still have the uniqueness constraints mentioned in above condition is known as a *minimal super key*.

   The first condition applies to both keys and super keys. The second condition is required only for keys.

Example: Consider the employee relation in Page no. 9. The attribute set {EId} is a key of employee because no two employee tuples can have the same value for EId.

Any set of attributes that include EId will form a super key.

1. {EId, Homephone, Name}
2. {EId, Age, Salary}
3. {Name, EId, Address}

However, the super key {EId, Name, Age} is not a key of EMPLOYEE, because removing Name or age or both from the set leaves us with a super key. Any super key formed from a single attributes is also a key. A key with multiple attributes must require all its attributes to have the uniqueness property.

A relation schema may have more than one key. In that case, each of the keys is called a *candidate key*.

Example: Employee relation has three candidate keys.
{Name, EId, Homephone}

One of the candidate keys is chosen as primary key of the relation.

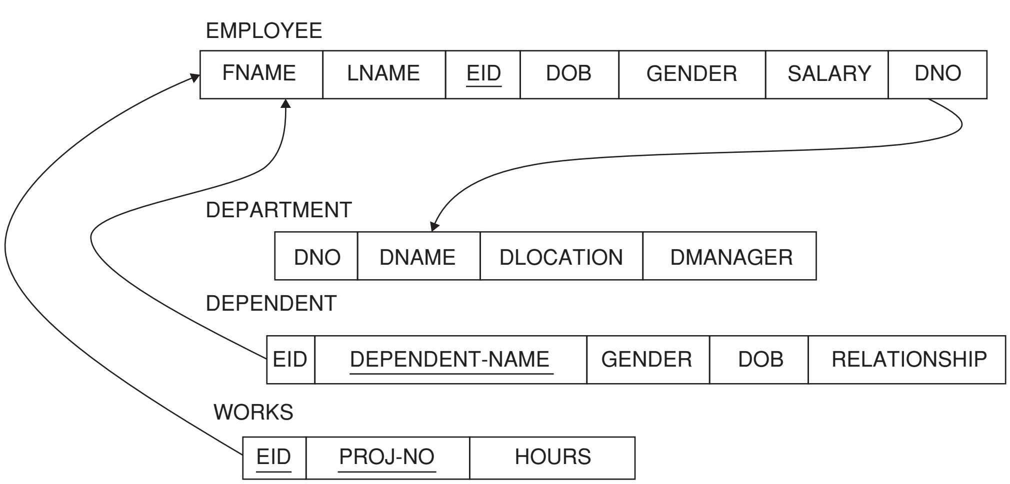
Another constraint on attributes specifies whether null values are permitted in tuples or not. If we want some tuples to have a valid (or) non-null value, we need to use NOT NULL constraint on that attribute.

Referential and entity integrity constraint

The entity Integrity constraint states that no primary key value can be null. If we have NULL values in the primary key column, we cannot identify some tuples in a relation.

1. Key constraints and entity Integrity constraints are specified on individual relations
2. Referential integrity constraint is specified between relations and used to maintain the consistency among tuples in the two relations.
3. Referential Integrity constraints states that a tuple in one relation that refers to another relation must refer to an existing tuple in that relation.
4. To understand the concept of Referential Integrity, first we have to understand the concept of FOREIGN KEY.
5. Suppose we have two relations R_1 and R_2. A set of attributes FK in relation schema R_1 is a foreign key of R_1 that references relation R_2 if it satisfies the following two rules:
   - The attributes in FK have the same domains as the primary key attributes PK of R_2, FK will have to refer to PK.
   - A value of FK in a tuple t_1 of the current state $r_1(R_1)$ either occurs as a value of PK for some tuple t_2 in the current state $r_2(R_2)$ or is null. We have t_1[FK] = t_2[PK], and we say that the tuple t_1 references to the tuple t_2. In this definition, R_1 is called the *referencing relation* and R_2 is the *referenced relation*.
6. A *foreign key* can refer to its own relation. We can diagrammatically display referential integrity constraints by drawing a directed Arc from each foreign key to the relation it references. The arrow head may point to the primary key of the referenced relation.

Example:



7. *Referential integrity rule*: The database must not contain any unmatched foreign key values.

If '*B*' References '*A*', then A must exist.

NOT NULL constraint

1. NOT NULL constraint restricts a column from having a NULL value. NOT NULL constraint can be applied to any column in a table.
2. We cannot give NULL values under that column
3. NOT NULL Constraint enforces a column to contain a proper value.
4. This constraint cannot be defined at table level.

Example: CREATE TABLE
student(RNo:INT Name:varchar(70) NOT NULL age:INT)
Suppose a row is inserted into the following table,

Insert into student values <11, NULL, 20>

In the schema, we enforced NOT NULL constraint on Name column, means Name cannot have NULL value, when the above insert command is executed, the system gives, NOT NULL constraint violation.

UNIQUE constraint

The column on which UNIQUE constraint is enforced should not have any duplicate values.

1. UNIQUE constraint can be enforced on any column except the primary key column.
2. By default primary key column will not accept any duplicate values that are handled by key constraint.
3. UNIQUE constraint can be applied at column level or table level.

Example: CREATE TABLE
student (RNo:INT Name:varchar(60) Grade:CHAR(1))
Assume that the table contains following tuples

Student

R no.	Name	Grade
11	Sita	B
12	Anu	A
13	Bala	A

Suppose the following tuple is inserted into the student table.

1. Insert into student values <14, 'Anu', '*B*'>
2. UNIQUE constraint is enforced on Name column, in the student table we have 'Anu', and again the new tuple contains name 'Anu', this Insert command violates the UNIQUE constraint.

CHECK constraint

This constraint is used to restrict a value of a column between a range.

1. When a value is inserted into particular column, before storing that, a check will be performed to see whether the values lie within the specified range.
2. If the value entered is out of range, it will not accept and violation happens.
3. It is like checking a condition before saving data into a column.

Example: Create table student (RNo:INT CHECK (Rno>0)
Name:varchar(60)
Dept:varchar(4))
Suppose the following tuple is inserted into student table.

1. Insert into student values <-4, 'Bhanu', 'CS'>
2. CHECK constraint is enforced on RNo column, the RNo should be greater than '0', but '-4' is given.
3. CHECK constraint is violated.

Creating table from a table: A view is called a *derived table* (or) *virtual table*, because the data stored in views is taken from already existing tables.

A view can also be defined as a logical subset of data from one or more tables.

Syntax:

```
CREATE    view view-name As
SELECT    column-names
FROM      table-name
WHERE     condition
```

Example: Consider the following table "sales".

Sales

Order-Id	Order Name	Previous Balance	Customer
21	Order 3	3000	Ana
22	Order 4	1000	Adam
23	Order 5	3000	Brat
24	Order 6	2000	John
25	Order 7	2000	Ana
26	Order 8	4000	Ana

Query to create a view:

```
CREATE view sales-view As
SELECT    *
FROM      Sales
WHERE     customer = 'Ana'
```

1. The data fetched from select statement will be stored in an object called 'sales-view'.
2. To display the contents stored in view, execute the following statement.

```
SELECT    *
FROM      Sales-view
```

Removal of specific rows:
Consider the following SQL query:

```
Delete    *
FROM   Sales
```

The above query will delete all the tuples from sales.

To remove specific rows, we have to specify the condition in WHERE clause.

Consider the table "sales" given in the above example.

Remove the rows from sales table whose previous balance is 3000.

SQL query:

```
Delete    *
FROM      Sales
WHERE     Previous-balance = 3000
```

Output:

Order Id	Order Name	Previous Balance	Customer
22	Order 4	1000	Adam
24	Order 6	2000	John
25	Order 7	2000	Ana
26	Order 8	4000	Ana

Referential actions: Referential Integrity can be violated if the value of any foreign key refers to a tuple that does not exist in the referenced relation.

When certain violations occur, we need to perform some alternate action. Those actions are as follows:

1. ON DELETE CASCADE
2. ON UPDATE CASCADE
3. ON DELETE SET NULL
4. ON DELETE SET DEFAULT

Example: Consider the given database:

SUPPLIERS:

Supplier Number	Supplier Name	Status	City
SN1	Suma	30	Hyderabad
SN2	Hari	20	Chennai
SN3	Anu	10	Hyderabad
SN4	Mahesh	20	Bombay
SN5	Kamal	30	Delhi

PARTS:

Part number	Part name	Colour	Weight	City
PN1	X	Red	13.0	Chennai
PN2	Y	Green	13.5	Bombay
PN3	X	Yellow	13.2	Hyderabad
PN4	Y	Green	14.1	Calcutta
PN5	Z	Red	14.3	Hyderabad
PN6	Z	Blue	14.2	Bombay

PROJECT:

Project Number	Project Name	City
PJ1	Display	Chennai
PJ2	OCR	Bombay
PJ3	RAID	Chennai
PJ4	SORTER	Hyderabad
PJ5	EDS	Chennai
PJ6	Tape	Bombay
PJ7	Console	Hyderabad

SHIPMENTS:

Supplier Number	Part Number	Project Number	Quantity
SN1	PN1	PJ1	300
SN1	PN1	PJ4	400
SN2	PN3	PJ1	350
SN2	PN3	PJ2	450
SN2	PN3	PJ3	640
SN2	PN3	PJ4	320
SN2	PN3	PJ5	330
SN2	PN3	PJ6	520
SN2	PN3	PJ7	480
SN2	PN5	PJ2	460
SN3	PN3	PJ1	440
SN3	PN4	PJ2	410
SN4	PN6	PJ3	310
SN4	PN6	PJ7	320
SN5	PN2	PJ2	340
SN5	PN2	PJ4	350
SN5	PN5	PJ5	360
SN5	PN5	PJ7	370
SN5	PN6	PJ2	380
SN5	PN1	PJ4	420
SN5	PN3	PJ4	440
SN5	PN4	PJ4	450
SN5	PN5	PJ4	400
SN5	PN6	PJ4	410

Consider the following statement:

```
DELETE FROM SUPPLIER
WHERE SUPPLIER – NUMBER = 'SN1'
```

It deletes the supplier tuple for supplier 'SN1'. The database has some other tables which have 'SN1' tuple (Shipments table). The application does not delete those suppliers, then it will find a violation, and an exception will be raised.

An alternate approach is possible, one that might be preferable in some cases, and that is for the system to perform an appropriate 'compensating action' that will guarantee that the overall result does still satisfy the constraint. In the example, the compensating action would be for the system to delete the shipments for supplier SN1 "automatically".

We can achieve this effect by extending the foreign key as indicated below:

```
CREATE TABLE SHIPMENT{.....}.......
FOREIGN KEY {SUPPLIER – NUMBER}
REFERENCES
SUPPLIER ON DELETE CASCADE
```

The specification ON DELETE CASCADE defines a delete rule for this particular foreign key, and the specification CASCADE is the referential action for that delete rule. The meaning of these specifications is that a DELETE operation on the suppliers relvar will 'Cascade" to delete matching tuples (if any) in the shipments relvar as well.

Same procedure is applied for all the referential actions.

Triggers

Triggers are precompiled procedures that are stored along with the database and invoked automatically whenever some specified event occurs.

Suppose we have a view called HYDERABAD - SUPPLIER defined as follows:

```
CREATE VIEW HYDERABAD-SUPPLIER
AS SELECT SUPPLIER - NUMBER, SUPPLIER-
NAME, STATUS
FROM SUPPLIER
WHERE CITY = 'HYDERABAD',
```

Normally, if the user tries to insert a row into this view, SQL will actually insert a row into the underlying base table SUPPLIERS with CITY value whatever the default is for the CITY column. Assuming that default is not Hyderabad, the net effect is that the new row will not appear in the view; therefore, let us create a triggered procedure as follows:

```
CREATE TRIGGER HYDERABAD -
SUPPLIER - INSERT
INSTEAD OF INSERT ON HYDERABAD
- SUPPLIER
REFERENCING NEW ROW AS R
FOR EACH ROW
INSERT INTO SUPPLIERS (SUPPLIER -
NUMBER, SUPPLIER - NAME, STATUS, CITY)
VALUES (R. SUPPLIER - NUMBER, R.
SUPPLIER - NAME, R. STATUS, 'HYDERABAD');
```

Inserting a row into the view will now cause a row to be inserted into the underlying base table with CITY value equal to Hyderabad inserted of the default value.

In general, CREATE TRIGGER specifies, among other things, an event, a condition, and an action.

The event is an operation on the database ("INSERT ON HYDERABAD - SUPPLIER" in the example)

1. The "condition" is a Boolean expression that has to evaluate to TRUE in order for the action to be executed.
2. The 'action' is the triggered procedure ("INSERT INTO SUPPLIERS . . .)
3. The event and condition together are sometimes called the *triggering event*. The combination of all three (event, condition, and action) is usually called a trigger.
4. Possible events include INSERT, DELETE, UPDATE, reaching end-of-transaction (COMMIT) reaching a specified time of day, exceeding a specified elapsed time, violating a specified constraint, etc.
5. A database that has associated triggers is sometimes called an active database.

Base Table Constraints

SQL-base table constraints are specified on either CERATE TABLE or ALTER TABLE. Each such constraint is a candidate key constraint, a foreign key constraint, or a CHECK constraint.

Candidate keys: An SQL candidate key definition takes one of the following two forms:

```
PRIMARY KEY (< column name comma list>)
UNIQUE (< column name comma list>)
The following example illustrates base table constraints of all three kinds:
CREATE TABLE SHIPMENTS
(SUPPLIER-NUMBER.      SUPPLIER-NUMBER
NOT NULL, PART - NUMBER PART-NUMBER
NOT NULL, QUANTITY NOT NULL
PRIMARY KEY (SUPPLIER - NUMBER,
PART  NUMBER)
FOREIGN KEY (SUPPLIER-NUMBER)
REFERENCES SUPPLIERS
ON DELETE CASCADE
ON UPDATE CASCADE,
FOREIGN KEY (PART-NUMBER)
REFERENCES PARTS
ON DELETE CASCADE
ON UPDATE CASCADE
CHECK(QUANTITY ≤ QUANTITY (0) AND
QUANTITY ≤ QUANTITY (1000));
```

A check constraint of the form CHECK (< column name > IS NOT NULL) can be replaced by a simple NOT NULL specification in the definition of the column.

Exercises

Practice Problems I

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider the following two tables T_1 and T_2. Show the output for the following operations:

Table T_1

P	Q	R
11	a	6
16	b	9
26	a	7

Table T_2

A	B	C
11	b	7
26	c	4
11	b	6

What is the number of tuples present in the result of given algebraic expressions?

(i) $T_1 \bowtie_{T1.P = T2.A} T_2$

(A) 2 (B) 3
(C) 4 (D) 5

(ii) $T_1 \bowtie_{T1.Q = T2.B} T2$

(A) 2 (B) 3
(C) 4 (D) .5

(iii) $T_1 \bowtie_{(T1.p = T2.A \text{ AND } T1.R = T2.C)} T_2$

(A) 1 (B) 2
(C) 3 (D) .4

2. Suppose $R_1(A, B)$ and $R_2(C, D)$ are two relation schemas. Let R_1 and R_2 be the corresponding relation instances. B is a foreign key that refers to C in R_2. If data in R_1 and R_2 satisfy referential integrity constraints, which of the following is true?

(A) $\pi_B(R_1) - \pi_c(R_2) = \phi$

(B) $\pi_C(R_2) - \pi_B(R_1) = \phi$

(C) $\pi_B(R_1) - \pi_C(R_2) \neq \phi$

(D) Both A and B

3. Consider the following relations:

A, B and C

A

Id	Name	Age
12	Arun	60
15	Shreya	24
99	Rohit	11

B

Id	Name	Age
15	Shreya	24
25	Hari	40
98	Rohit	20
99	Rohit	11

C

Id	Phone	Area
10	2200	02
99	2100	01

How many tuples does the result of the following relational algebra expression contain? Assume that the scheme of $(A \cup B)$ is the same as that of A.

$(A \cup B) \bowtie_{A.Id > 40 \vee c.Id < 15} C$

(A) 6 (B) 7
(C) 8 (D) 9

4. Consider the relations A, B and C given in Question 3. How many tuples does the result of the following SQL query contain?

```
SELECT   A.Id
FROM           A
WHERE    A.Age>
ALL            (SELECT B.Age
FROM           B
WHERE    B.Name = 'Arun')?
```

(A) 0 (B) 1
(C) 2 (D) 3

5. Consider a database table T containing two columns X and Y each of type integer. After the creation of the table, one record ($X = 1$, $Y = 1$) is inserted in the table. Let MX and MY denote the respective maximum value of X and Y among all records in the table at any point in time. Using MX and MY, new records are inserted in the table 128 times with X and Y values being MX + 1, 2 * MY + 1, respectively. It may be noted that each time after the insertion, values of MX and MY change. What will be the output of the following SQL query after the steps mentioned above are carried out?

SELECT Y FROM T WHERE $X = 7$;?

(A) 15 (B) 31
(C) 63 (D) 127

6. Database table by name loan records is given below:

Borrower	Bank Manager	Loan Amount
Ramesh	Sunderajan	10000
Suresh	Ramgopal	5000
Mahesh	Sunderajan	7000

What is the output of the following SQL Query SELECT count (*)

FROM((SELECT Borrower, Bank-manager

FROM Loan-Records)AS S

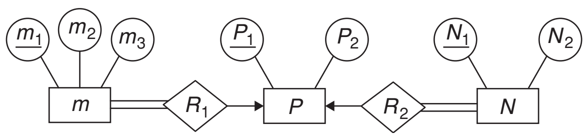
NATURAL JOIN

(SELECT Bank-manager, Loan-Amount

FROM Loan-Records) AS T);

(A) 3 (B) 4
(C) 5 (D) 6

7. Consider the following ER diagram:



What is the minimum number of tables needed to represent M, N, P, R_1, R_2?

(A) 2 (B) 3
(C) 4 (D) 5

8. Let E_1 and E_2 be two entities in an ER diagram with simple single-valued attributes. R_1 and R_2 are two relationships between E_1 and E_2, where R_1 is one-to-many and R_2 is many-to-many. R_1 and R_2 do not have any attributes of their own. What is the minimum number of tables required to represent this situation in the relational model?

(A) 2 (B) 3
(C) 4 (D) 5

9. The following table has two attributes A and C where A is the primary key and C is the foreign key referencing A with ON DELETE CASCADE.

A	C
2	4
3	4
4	3
5	2
7	2
9	5
6	4

What is the set of all tuples that must be additionally deleted to preserve referential integrity when the tuple (2, 4) is deleted?

(A) (5, 2),(7, 2) (B) (5, 2), (7, 2),(9, 5)
(C) (5, 2),(9, 5) (D) (2, 4), (7, 2)

10. Consider the following SQL query

SELECT DISTINCT $a_1, a_2, a_3 \ldots a_n$

FROM $R_1, R_2 \ldots R_m$

WHERE P

For any arbitrary predicate P, this query is equivalent to which relational algebra expression?

(A) $\Pi_{a_1, a_2, \ldots a_n}(\sigma_p R_1 \times R_2 \times \ldots \times R_m)$

(B) $\sigma_{a_1, a_2, \ldots a_n}(\sigma_p R_1 \times R_2 \times \ldots \times R_m)$

(C) $\sigma_{a_1, a_2, \ldots a_n}(\Pi_p R_1 \times R_2 \times \ldots \times R_m)$

(D) $\Pi_{R_1, R_2, \ldots Rm}(\sigma_p a_1 \times a_2 \times \ldots \times (a_n)$

11. Consider the following relation schema pertaining to a student's database:

Student (Rollno, name, address)

Enroll (Rollno, courseno, coursename)

Where the primary keys are shown underlined. The number of tuples in the student and Enroll tables are 120 and 6, respectively. What are the maximum and minimum number of tuples that can be present in

(student * Enroll)

Where '*' denotes natural join?

(A) 6, 6 (B) 6, 120
(C) 120, 6 (D) 120, 120

12. A relational schema for a train reservation database is given below

Table 4 *Passenger*

Pid	P Name	Age
0	'Sachin'	65
1	'Rahul'	66
	'Sourav'	67
3	'Anil'	69

Table 5 *Reservation*

Pid	Class	Tid
0	AC	8200
1	AC	8201
2	SC	8201
5	AC	8203
1	SC	8204
3	AC	8202

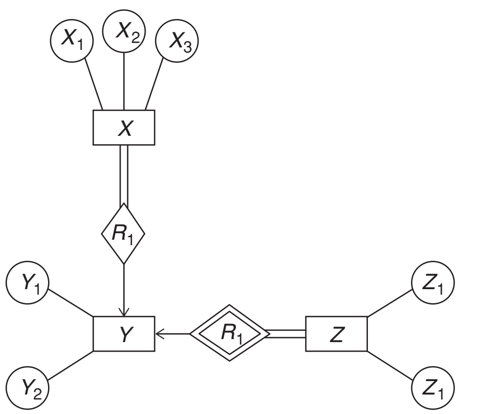
What pid's are returned by the following SQL query for the above instance of the tables?

```
SELECT   pid
FROM     Reservation
WHERE    class = 'AC' AND
         EXISTS (SELECT *
                 FROM passenger
         WHERE age > 65 AND
         Passenger.pid = Reservation.pid)
```

(A) 0, 1 (B) 1, 3
(C) 1, 5 (D) 0, 3

13. Given {customer} is a candidate key, [customer name, customer street} is another candidate key then
(A) {customer id, customer name} is also a candidate key.
(B) {customer id, customer street} is also a candidate key.
(C) {customer id, customer name, customer street} is also a candidate key.
(D) None

Common data for questions 14 and 15: Consider the following diagram,



14. The minimum number of tables needed to represent X, Y, Z, R_1, R_2 is
(A) 2 (B) 3
(C) 4 (D) 5

15. Which of the following is a correct attribute set for one of the tables for the correct answer to the above questions?
(A) $\{X_1, X_2, X_3, Y_1\}$ (B) $\{X_1, Y_1, Z_1, Z_2\}$
(C) $\{X_1, Y_1, Z_1\}$ (D) $\{M_1, Y_1\}$

16. UPDATE account SET
DA = basic * .2,
GROSS = basic * 1.3,
Where basic > 2000;
(A) The above query displays DA and gross for all those employees whose basic is ≥ 2000
(B) The above query displays DA and gross for all employees whose basic is less than 2000
(C) The above query displays DA as well as gross for all those employees whose basic is >2000
(D) Above all

17. Which of the following query transformations is correct?
R_1 and R_2 are relations C_1, C_2 are selection conditions and A_1 and A_2 are attributes of R_1
(A) $\sigma_{C1}(\sigma_{C1}(R_1)) \to \sigma_{C2}(\sigma_{C2}(R_1))$
(B) $\sigma_{C1}(\sigma_{A1}(R_1)) \to \sigma_{A1}(\sigma_{C1}(R_1))$
(C) $\pi_{A2}(\pi_{A}(R_1)) \to \pi_{A}(\pi_{A2}(R_1))$
(D) All the above

18. Consider the following query select distinct $a_1, a_2, \ldots a_n$ from $r_1, r_2 \ldots r_m$ where P for an arbitrary predicate P, this query is equivalent to which of the following relational algebra expressions:
(A) $\pi_{a_1 \ldots a_n} \sigma_p (r_1 \times r_2 \times \ldots \times r_m)$
(B) $\pi_{a_1 \ldots a_n} \sigma_p (r_1 \times r_2 \times r_3 \times \ldots . \times r_m)$
(C) $\sigma_{a_1 \ldots a_n} \pi_p (r_1 \times r_2 \times \ldots \times r_m)$
(D) $\sigma_{a_1 \ldots a_n} \pi_p (r_1 \times r_2 \times \ldots \times r_m)$

19. The relational algebra expression equivalent to the following tuple calculus expression
$\{a\}\ a \in r \wedge (a[A] = 10 \wedge a[B] = 20)$ is
(A) $\sigma_{(A = 10\ r\ B = 20)}$r
(B) $\sigma_{(A = 10)}(r) \cup \sigma_{(B = 20)}(r)$
(C) $\sigma_{(A = 10)}(r) \cap \sigma_{(B = 20)}(r)$
(D) $\sigma_{(A = 10)}(r) - \sigma_{(B = 20)}(r)$

20. Which of the following is/are wrong?
(A) An SQL query automatically eliminates duplicates.
(B) An SQL query will not work if there are no indexes on the relations.
(C) SQL permits attribute names to be repeated in the same relation
(D) All the above

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. If *ABCDE* are the attributes of a table and *ABCD* is a super key and *ABC* is also super key then
(A) *A B C* must be candidate key
(B) *A B C* cannot be super key
(C) *A B C* cannot be candidate key
(D) *A B C* may be candidate key

2. The example of derived attribute is
(A) Name if age is given as other attribute
(B) Age if date_of_birth is given as other attribute
(C) Both (A) and (B)
(D) None

3. The weak entity set is represented by
(A) box
(B) ellipse
(C) diamond
(D) double outlined box

4. In entity relationship diagram double lines indicate
(A) Cardinality
(B) Relationship
(C) Partial participation
(D) Total participation

5. An edge between an entity set and a binary relationship set can have an associated minimum and maximum cardinality, shown in the form 1… h where 1 is the minimum and h is the maximum cardinality A minimum value 1 indicates:
(A) total participation (B) partial participation
(C) double participation (D) no participation

6. Let R be a relation schema. If we say that a subset k of R is a super key for R, we are restricting R, we are restricting consideration to relations $r(R)$in which no two district tuples have the same value on all attributes in K. That is if t_1 and t_2 are in r and $t_1 \uparrow t_2$
(A) $t_1[k] = 2t_2[K]$ (B) $t_2[K] = 2t_1[k]$
(C) $t_1[k] = t_2[k]$ (D) $t_1[k] \uparrow t_2[k]$

7. Which one is correct?
(A) Primary key ⊂ Super key ⊂ Candidate key
(B) Candidate key ⊂ Super key ⊂ Primary key
(C) Primary key ⊂ Candidate key ⊂ Super key
(D) Super key ⊂ Primary key ⊂ Candidate key

8. If we have relations $r1(R1)$ and $r2(R2)$, then $r1$ ($r2$ is a relation whose schema is the
(A) concatenation (B) union
(C) intersection (D) None

9. Match the following:

I	Empid	1	Multivalued
II	Name	2	Derived
III	Age	3	Composite
IV	Contact No.	4	Simple

(A) I – 4, II – 3, III – 2, Iv – 1
(B) I – 3, II – 2, III – 4, Iv – 1
(C) I – 2, II – 1, III – 4, Iv – 3
(D) I – 1, II – 3, III – 2, IV – 4

10. Match the following:

I	Double-lined ellipse	1	Multivalued attribute
II	Double line	2	Total participation
III	Double-lined box	3	Weak entity set
IV	Dashed ellipse	4	Derived attribute

(A) I – 1, II – 2, III – 3, IV – 4
(B) I – 2, II – 3, III – 4, IV – 1
(C) I – 3, II – 4, III – 2, IV – 2
(D) I – 4, II – 3, III – 2, IV –1

11. The natural join is a
(A) binary operation that allows us to combine certain selections and a Cartesian product into one operation
(B) unary operations that allows only Cartesian product
(C) query which involves a Cartesian product and a projection
(D) None

12. The number of entities participating in the relationship is known as
(A) maximum cardinality (B) composite identifiers
(C) degree (D) None

13 A minimum cardinality of 0 specifies
(A) non-participation
(B) partial participation
(C) total participation
(D) zero participation

14. What is not true about weak entity?
(A) They do not have key attributes.
(B) They are the examples of existence dependency.
(C) Every existence dependency results in a weak entity
(D) Weak entity will have always discriminator attributes

15. Which one is the fundamental operation in the relational algebra?
(A) Natural join (B) Division
(C) Set intersection (D) Cartesian product

16. For the given tables

A

X	Y
a_1	b_1
a_2	b_1
a_1	b_2
a_2	b_2

B

Y
b_1
b_2

$A \div B$ will return
(A) a_1, a_2 (B) a_1
(C) a_2 (D) None

17. The number of tuples selected in the above answer is
(A) 2 (B) 1
(C) 0 (D) 4

Common data for questions 18 and 19: Consider the following schema of a relational database.

Emp (empno, name, add)

Project (Pno, Prame)

Work on (empno, Pno)

Part (partno, Pname, qty, size)

Use (empno, pno, partno, no)

18. ((name(emp) ((name(emp ⋈ workon) displays
(i) The names of the employees who are not working in any project
(ii) The names of the employees who were working in every project.
(A) Only (i) (B) Only (ii)
(C) Both (A) and (B) (D) None

19. List the partno and names of the parts used in both the projects DBMS & MIS:

(A) $\sigma_{partno,\ pname,}{}^{(part} \bowtie {}^{(}\pi_{partno} (\sigma_{pname} = \text{“DBMS”}^{(project)} \bowtie$ ${}^{use).}\cap \pi_{partno} (\sigma_{pname} = \text{“MIS”}^{(project)} \bowtie {}^{use)})$

(B) (partno, pname(part $\bowtie$ ((partno ((pname = “DBMS”(project $\bowtie$ use) ((partno(σ_{pname} = “MIS”$^{(project)} \bowtie {}^{use)}$))

(C) $\pi_{partno,\,pname}(\text{part} \bowtie (\sigma_{partno} (\sigma_{pname} = \text{“DBMS”}^{(project} \bowtie$ ${}^{use)}$ ((partno ((pname = “MIS”(project) $\bowtie$ use)))

(D) None

20. The following query shows. SELECT job-status, sum (basic – salary) AVG (basic – salary) from employees group by job – status.

(i) It shows job status, sum, AVG of all data

(ii) It shows job status, Sum, AVG, with group by clause in use.

(A) only (i)
(B) only (ii)
(C) both (A) and (B)
(D) None

Previous Years' Questions

1. Let E_1 and E_2 be two entities in an E/R diagram, with simple single-valued attributes. R_1 and R_2 are two relationships between E_1 and E_2, where R_1 is one-to-many and R_2 is many-to-many. R_1 and R_2 do not have any attributes of their own. What is the minimum number of tables required to represent this situation in the relational model? **[2005]**

(A) 2
(B) 3
(C) 4
(D) 5

2. The following table has two attributes A and C where A is the primary key and C is the foreign key referencing A with on-delete cascade.

A	C
2	4
3	4
4	3
5	2
7	2
9	5
6	4

The set of all tuples that must be additionally deleted to preserve referential integrity when the tuple (2, 4) is deleted is: **[2005]**

(A) (3, 4) and (6, 4)
(B) (5, 2) and (7, 2)
(C) (5, 2), (7, 2) and (9, 5)
(D) (3, 4), (4, 3) and (6, 4)

3. Which of the following tuple relational calculus expression(s) is/are equivalent to $\forall t \in r\ (P(t))$?

I. $\neg \exists t \in r\ (P(t))$

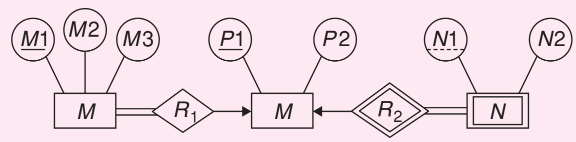
II. $\exists t \notin r\ (P(t))$

III. $\neg \exists t \in r\ (\neg P(t))$

IV. $\exists t \in r\ (\neg P(t))$ **[2008]**

(A) I only
(B) II only
(C) III only
(D) III and IV only

Common data for questions 4 and 5: Consider the following ER diagram:



4. The minimum number of tables needed to represent M, N, P, R_1, R_2 is? **[2008]**

(A) 2
(B) 3
(C) 4
(D) 5

5. Which of the following is a correct attribute set for one of the tables for the correct answer to the above question? **[2008]**

(A) $\{M1, M2, M3, P1\}$
(B) $\{M1, P1, N1, N2\}$
(C) $\{M1, P1, N1\}$
(D) $\{M1, P1\}$

6. Consider a relational table with a single record for each registered student with the following attributes.

1. *Registration_Num*: Unique registration number of each registered student
2. *UID*: Unique identity number, unique at the national level for each citizen
3. *BankAccount_Num*: Unique account number at the bank. A student can have multiple accounts or joint accounts. This attribute stores the primary account number
4. *Name*: Name of the student
5. *Hostel_Room*: Room number of the hostel

Which of the following options is incorrect? **[2011]**

(A) *BankAccount_Num* is a candidate key
(B) *Registration_Num* can be a primary key
(C) *UID* is a candidate key if all students are from the same country
(D) If S is a super key such that $S \cap UID$ is NULL then $S \cup UID$ is also super key.

7. Given the basic ER and relational models, which of the following is incorrect? **[2012]**

(A) An attribute of an entity can have more than one value
(B) An attribute of an entity can be composite
(C) In a row of a relational table, an attribute can have more than one value
(D) In a row of a relational table, an attribute can have exactly one value or a NULL value

8. An ER model of a database consists of entity types A and B. These are connected by a relationship R which does not have its own attribute, Under which one of the following conditions, can the relational table for R be merged with that of A? **[2017]**
(A) Relationship R is one-to-many and the participation of A in R is total.
(B) Relationship R is one-to-many and the participation of A in R is partial.
(C) Relationship R is many-to-one and the participation of A in R is total.
(D) Relationship R is many-to-one and the participation of A in R is partial.

9. In an Entity-Relationship (ER) model, suppose R is a many-to-one relationship from entity set $E1$ to entity set $E2$. Assume that $E1$ and $E2$ participate totally in R and that the cardinality of $E1$ is greater than the cardinality of $E2$.
Which one of the following is true about R? **[2018]**
(A) Every entity in $E1$ is associated with exactly one entity in $E2$.
(B) Some entity in $E1$ is associated with more than one entity in $E2$.
(C) Every entity in $E2$ is associated with exactly one entity in $E1$.
(D) Every entity in $E2$ is associated with at most one entity in $E1$.

Chapter 2

Structured Query Language

LEARNING OBJECTIVES

- *Relational algebra*
- *Select operator*
- *Project operator*
- *Set operators*
- *Union compatible relations*
- *Union operation*
- *Aggregate operators*
- *Correlated nested queries*
- *Relational calculus*
- *Tuple relational calculus*
- *Tuple relational calculus*
- *DML*
- *Super key*
- *SQL commands*

Relational Algebra

1. A set of operators (unary or binary) that take relation instances as arguments and return new relations.
2. Gives a procedural method of specifying a retrieval query
3. Forms the core component of a relational query engine
4. *SQL* queries are internally translated into *RA* expressions
5. Provides a framework for query optimization

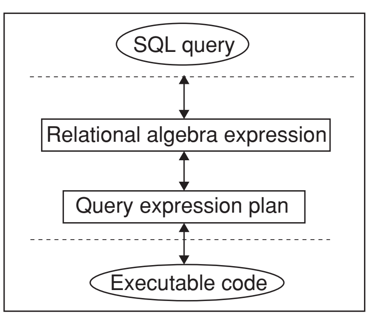

Figure 1 *Role of relational algebra in DBMS:*

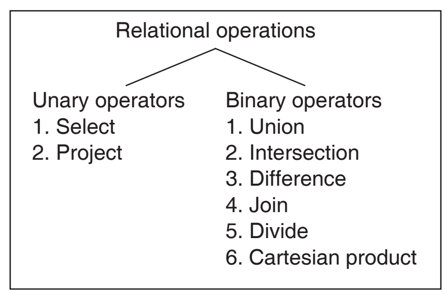
Relational Operations

A collection of simple 'low-level' operations used to manipulate relations.

1. It provides a procedural way to query a database.
2. Input is one (or) more relations.
3. Output is one relation.



Select Operator (σ)

Select operator is an unary operator. It can be used to select those tuples of a relation that satisfy a given condition.

Notation: $\sigma_{\theta}(r)$

σ: Select operator(read as sigma)

θ: Selection condition

r: Relation name

Result is a relation with the same scheme as r consisting of the tuples in r that satisfy condition θ

Syntax: $\sigma_{\text{condition}}$ (relation)

Example:

Table 2.1 *Person*

Id	Name	Address	Hobby
112	John	12, SP Road	Stamp collection
113	John	12, SP Road	Coin collection
114	Mary	16, SP Road	Painting
115	Brat	18, GP Road	Stamp collection

$\sigma_{\text{Hobby = 'stamp. Collection'}}$(person)

The above given statement displays all tuples (or) records with hobby 'stamp collection'.

Output:

Id	Name	Address	Hobby
112	John	12, SP Road	Stamp collection
115	Brat	18, GP Road	Stamp collection

Selection condition can use following operators:
$<, \leq, >, \geq, =, \neq$

1. <attribute> operator <attribute>
2. <attribute> operator <constant>

Example: Salary ≥ 1000

3. <Condition> AND/OR <condition>

Example: (Experience > 3) AND (Age < 58)

4. NOT <condition>

Selection operation examples:

1. $\sigma_{\text{Id > 112 OR Hobby = 'paint'}}$ (person)
   It displays the tuples whose ID > 112 or Hobby is paint
2. $\sigma_{\text{Id > 112 AND Id < 115}}$ (person)
   It displays tuples whose ID is greater than 112 and less than 115
3. $\sigma_{\text{NOT (hobby = 'paint')}}$ (person)
   It displays tuples whose hobby is not paint
4. $\sigma_{\text{Hobby} \neq \text{'paint'}}$ (person)
   It displays tuples whose hobby is not paint, displays all tuples other than hobby paint.
   Selection operator: Produces table containing subset of rows of argument table which satisfies condition.

Project Operator (π)

The project operator is unary operator. It can be used to keep only the required attributes of a relation instance and throw away others.

Notation: $\pi_{A2,\ A2,\ \ldots\ Ak(r)}$ Where $A_1, A_2, \ldots A_K$ is a list L of desired attributes in the scheme of r.

Result = $\{(V_1, V_2, \ldots V_K)/V_i \in \text{DOM}(A_i), 1 \leq i \leq k$ and there is some tuple t in r, such that $t.A_1 = v_1, t.A_2 = v_2, \ldots t.A_K = V_K\}$

$\pi_{\text{Attribute List}}$ (Relation)

Take table 2.1 as reference.

1. π_{Name} (person)

Output:

Name
John
Mary
Bart

In the output table, John name has appeared once, project operation eliminated duplicates.

2. $\pi_{\text{Name, address}}$ (person)

Output:

Name	Address
John	12, SP Road
Mary	16, SP Road
Bart	18,GP Road

Expressions:

$\pi_{\text{id, name}}(\sigma_{\text{hobby = 'stamp collection' OR Hobby= 'coin collection'}}(\text{person}))$

Output:

Id	Name
112	John
115	Bart

The above given relational algebra expression gives Ids, names of a person whose hobby is either stamp collection (or) coin collection.

Set Operators

Union (∪), Intersection (∩), set difference (–) are called *set operators*. Result of combining two relations with a set operator is a relation ⇒ all its elements must be tuples having same structure. Hence scope of set operations is limited to union compatible relations.

Union Compatible Relations

Two relations are union compatible if

1. Both have same number of columns
2. Names of attributes are same
3. Corresponding fields have same type
4. Attributes with the same name in both relations have same domain.
5. Union compatible relations can be combined using Union, Intersection, and set difference.

Example:

Consider the given tables.
Person (SSN, Name, Address, Hobby)
Professor (Id, Name, office, phone)
person and professor tables are not union compatible.

Union

The result of union will be a set consisting of all tuples appearing in either or both of the given relations. Relations cannot contain a mixture of different kinds of tuples, they must be 'tuple – homogeneous'. The union in the relational algebra is not the completely general mathematical union; rather, it is a special kind of union, in which we require the two input relations to be of the same type.

The general definition of relational union operator:

Given are two relations '*a*' and '*b*' of the same type. The union of those two relations, a union *b*, is a relation of the same type, with body consisting of all tuples '*t*' such that '*t*' appears in a or *b* or both.

* Union operation eliminates duplicates.

Here is a different but equivalent definition:

Given are two relations '*a*' and '*b*' of the same type. The union of those two relations, *a* union *b*, is a relation of the same type, with body consisting of all tuples t such that t is equal to (i.e., is a duplicate of) some tuple in *a* or *b* or both.

Union Operation (U)

When union operation is applied on two tables it gives all the tuples in both without Repetition.

Example:

Table 2 *Result of union operation*

R

Roll. no.	Name	Semester	Percentage
22	Arun	7	45%
31	Bindu	6	55%
58	Sita	5	35%

S

Roll no.	Name	Semester	Percentage
28	Suresh	4	65%
31	Bindu	6	55%
44	Pinky	4	75%
58	Sita	5	35%

$R \cup S$

Roll no.	Name	Semester	Percentage
22	Arun	7	45%
31	Bindu	6	55%
58	Sita	5	35%
44	Pinky	4	75%
28	Sita	5	35%

Intersection

Like union, Intersection operator requires its operands to be of the same type. Given are two relations *a* and *b* of the same type, then, the intersection of those two relations, '*a*' INTERSECT '*b*', is a relation of the same type, with body consisting of all tuples t such that t appears in both '*a*' and '*b*'.

Intersection operation returns tuples which are common to both tables

Table 3 *Result of intersection operation*

$R \cap S =$

Roll no.	Name	Semester	Percentage
31	Bindu	6	55%
58	Sita	5	35%

Difference

Like union and intersection, the relational difference operator also requires its operands to be of the same type. Given are two relations '*a*' and '*b*' of the same type, Then, the difference between those two relations, '*a*' MINUS '*b*' (in that order), is a relation of the same type, with body consisting of all types t such that t appears in a and not *b*.

1. MINUS has a directionality to it, just as subtraction does in ordinary arithmetic (e.g., '6 – 3' and '3 – 6' are not the same thing)
2. Redundant duplicate rows are always eliminated from the result of UNION, INTERSECTION, EXCEPT operations.
3. SQL also provides the qualified variants UNION ALL, INTERSECT ALL and EXCEPT ALL, where duplicates are retained

Set difference operation returns the tuples in the first table which are not matching with the tuples of other table.

Table 4 *Result of R – S*

R – S =

Roll no.	Name	Semester	Percentage
22	Arun	7	45%

Table 5 *Result of S – R*

S – R =

Roll no.	Name	Semester	Percentage
28	Suresh	4	65%
44	Pinky	4	75%

* R – S ≠ S –R (both are different)

Example:

A

Supplier number	Supplier name	Status	City
SN1	MAHESH	40	HYDERABAD
SN3	SURESH	40	HYDERABAD

B

Supplier number	Supplier number	Status	City
SN3	SURESH	40	HYDERABAD
SN4	RAMESH	30	CHENNAI

UNION ($A \cup B$)

Supplier number	Supplier name	Status	City
SN1	MAHESH	40	HYDERABAD
SN3	SURESH	40	HYDERABAD
SN4	RAMESH	30	CHENNAI

INTERSECTION ($A \cap B$)

Supplier number	Supplier name	Status	City
SN3	SURESH	40	HYDERABAD

DIFFERENCE ($A - B$)

Supplier name	Supplier name	Status	City
SN1	MAHESH	40	HYDERABAD

DIFFERENCE ($B - A$)

Supplier name	Supplier name	Status	City
SN4	RAMESH	30	CHENNAI

Cartesian Product

The Cartesian product of two sets is the set of all ordered pairs such that in each pair, the first element comes from the first set and the second element comes from second set.

The result consists of all the attributes from both of the two input headings. We define the Cartesian product of two relations '*a*' and '*b*', as

'*a*' times '*b*', where *a* and *b* have no common attribute names (If we need to construct the Cartesian product of two relations that do have any such common attribute names, therefore, we must use the RENAME operator first to rename attributes appropriately).

The Cartesian product operation is also known as CROSS PRODUCT. This is also a binary set operation, but the relations on which it is applied need not to be union compatible. This operation is used to combine tuples from two relations in a combinational fashion.

Example:

R

A	B
X_1	X_2
X_3	X_4

S

C	D
Y_1	Y_2
Y_3	Y_4

$R \times S =$

A	B	C	D
X_1	X_2	Y_1	Y_2
X_1	X_2	Y_3	Y_4
X_3	X_4	Y_1	Y_2
X_3	X_4	Y_3	Y_4

Example: Transcript (StuId, coursecode, semester, grade) Teaching (ProfId, coursecode, semester)

$$\pi_{\text{stuId,coursecode}} (\text{Transcript}) \times \pi_{\text{profId,coursecode}} (\text{Teaching})$$

The above expression returns

Table 6 *Result of cross product*

Stu Id	Course code	Prof Id	Course code
...	...	...	...

Aggregate Operators

SQL Supports the usual aggregate operators COUNT, SUM, AVG, MAX, MIN, EVERY and ANY, but there are a few SQL-specific points.

1. The argument can optionally be preceded by the keyword DISTINCT, for example SUM (DISTINCT column -name) to indicate that duplicates are to be eliminated before the aggregation is done. For MAX, MIN, EVERY and ANY, however, DISTINCT has no effect and should not be specified.
2. The operator COUNT (*), for this DISTINCT is not allowed, and is provided to count all rows in a table without any duplicate elimination.
3. Any NULLS in the argument column are eliminated before the aggregation is done, regardless of whether DISTINCT is specified, except in the case of COUNT (*), where nulls behave as if they were values.
4. After NULLS if any have been eliminated, if what is left is an empty set, COUNT returns zero. The other operators return NULL.

AVG, MIN, MAX, SUM, COUNT

These functions operate on the multiset of values of column of a relation and returns a value.

1. Find the average account balance at the Perryridge branch.

Solution: SELECT AVG (balance) FROM account WHERE branch.name = 'perryridge'

2. Find the number of tuples in customer relation.

Solution: SELECT count (*) FROM customer

3. Find the number of depositors for each branch.

Solution: SELECT branch.name, COUNT (distinct customer-name) FROM depositor, account WHERE depositor. account-no = account account-no GROUPBY branch-name.

Nested Queries

Some queries require that existing values in the database be fetched and then used in a comparison condition.

Such queries can be conveniently formulated by using nested queries, which are complete SELECT – FROM –WHERE blocks within the WHERE clause of another query. The other query is called the *outer query*.

In-Comparison Operator

The comparison operator IN, which compares a value '*v*' with a set of values '*V*' and evaluates to TRUE if '*v*' is one of the elements in *V*.

Example: Consider the given database scheme and the statement:

EMPLOYEE

FNAME	INITIAL	LNAME	ENO	DOB	ADDRESS	SALARY	DNO

DEPARTMENT

D NAME	DNO	MANAGER-NO

DEPARTMENT–LOCATIONS

DNO	D-LOCATION

PROJECT

PNAME	PNO	P-LOCATION	DNO

WORKS–ON

ENO	PNO	HOURS

Example: Select distinct PNO from project where PNO IN (select PNO from project, department, employee where P. DNO = D. DNO AND MANAGER. NO = ENO AND LNAME = 'RAMYA')

The first query selects. The project numbers that have a 'Ramya' involved as manager, while the second selects the project numbers of projects that have a 'Ramya' involved as worker.

If a nested returns a single value, in such cases, it is permissible to use = instead of IN for the comparison operator.

In general, the nested query will return a table, Which is a set of multiset of tuples.

* SQL allows the use of tuples of values in comparisons by placing them within parentheses.

Example: SELECT DISTINCT ENO FROM WORKS - ON WHERE (PNO, HOURS) IN (SELECT PNO, HOURS FROM WORKS - ON WHERE ENO = 929).

This query will select the employee numbers of all employees who work on the same (PROJECT, HOURS) combination on some project a particular employee whose ENO = '929' works on. In this example, the IN operator compares the subtuple of values in parentheses (PNO, HOURS) for each tuple in works on with the set of union-compatible tuples produced by the nested query.

Correlated nested queries: Nested queries can be evaluated by executing the sub query (or) Inner query once and substituting the resulting value (or) values into the WHERE clause of the outer query.

1. In co-related nested queries, the inner query depends on the outer query for its value.
2. Sub-query is executed repeatedly, once for each row that is selected by the outer query.
3. A correlated subquery is a sub query that contains a reference to a table that also appears in the outer query.

Example: Consider the following correlated nested query:

SELECT *
FROM table1
WHERE col1 ≥ ALL
(SELECT col1 FROM table2 WHERE table2. col2 = table1. col2)

1. The subquery contains reference to a column of table1, even though the sub-queries FROM clause does not mention a table table1
2. SQL has to check outside the sub-query and find Table 1 in the outer query
3. Suppose that Table 1 contains a row where col1 = 3 and col2 = 4 and Table 2 contains a row where col1 = 5 and col2 = 4
4. The expression

   WHERE col1 ≥ All (SELECT col1 FROM table2

   3 ≥ 5 (false)

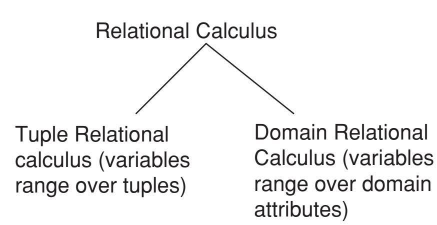
   (WHERE condition TRUE) Table1. col2 = table2. col2 4 = 4

   So the expression as a whole is FALSE.
5. It is evaluated from outside to inside

Relational Calculus

Relational calculus can define the information to be retrieved

1. In this, there is no specific series of operations.
2. Relational algebra defines the sequence of operations.
3. Relational calculus is closer to how users would formulate queries, in terms of information requirements, rather than in terms of operations.



4. Relational calculus is based on predicate logic, gives the usual quantifiers to construct complex queries.

Tuple Relational Calculus

Example: Employee

E Id	F Name	L Name	S alary
201	John	James	3000
202	Brat	Frank	2000
203	Mary	Jennifer	3000
204	Adam	Borg	2000
205	Smith	Joyce	1000

Query 1: Display the employees whose salary is above 2000.

$\{E \mid \exists E \in \text{Employee}(E.\text{salary} > 2000)\}$

Output:

E Id	F Name	L Name	Salary
201	John	James	3000
203	Mary	Jennifer	3000

Query 2: Display the employee Ids whose salary is above 1000 and below 3000.

$\{P \mid \exists E \in \text{Employee } ((E.\text{salary} > 1000 \wedge E.\text{salary} < 3000) \wedge P.\text{EId} = E.\text{EId})\}$

P is a table, in which EIds are stored, from tuples which satisfies the given condition.

TUPLE RELATIONAL CALCULUS

A non-procedural language, where each query is of the form $\{t \mid p(t)\}$. It is a set of all tuples *t* such that predicate *p* is true for *t*, *t* is a tuple variable, *t* [*A*] denotes the value of tuple '*t*' on attribute A.

$$\{T \mid p\ (T)\}$$

T is a tuple and *P* (*T*) denotes a formula in which tuple variable *T* appears.

1. $\forall \times (P(X))$

   $\forall$ is called the universal or 'for all' quantifier because every tuple in 'the universe of' tuples must make *F* true to make the quantified formula true.
   Only true if $p(X)$ is true for every *X* in the universe.

   Example: $\forall \times (\text{x.color} = \text{'Red'})$
   means everything that exists is red.

   Example: $\forall \times ((x \in \text{Boats}) \Rightarrow (X.\text{ color} = \text{'Red'}))$
   '$\Rightarrow$' is a logical implication. $a \Rightarrow b$ means that if a is true, *b* must be true
   (or)
   $\exists \times \in \text{Boats } (X.\text{color} = \text{'Red'})$
   For every '*x*' in the boats relation, the color must be red.

2. $\exists \times (P(X))$

   $\exists$ is called the *existential* or '*there exists*' quantifier because any tuple that exists in 'the universe of' tuples may take *F* true, to make the quantified formula true.

   Example: $\exists \times ((X \in \text{Boats}) \wedge \text{X.color}) = \text{'Red'})$
   There exists a tuple *X* in the boats relation whose color is red.
   (or)
   $\exists \times \in \text{Boats (X.color} = \text{'Red')}$

Examples:

1. Find all sailors with rating above 8.

Sailors:

Sid	Sname	Rating	Age
28	Yuppy	9	35
35	Rubber	8	55
44	grove	5	35
58	rusty	10	35

Solution: $\{s \mid s \in \text{sailors} \wedge s.\text{ rating} > 8\}$

Output

$R =$

Sid	Sname	Rating	Age
28	yuppy	9	35
58	rusty	10	35

2. Find names and ages of sailors with rating > 8.

Solution: $\{R \mid \exists S \in \text{sailors (s.rating} > 8 \wedge \text{R.sname} = \text{s.name} \wedge \text{R.age} = \text{s.age})$

Output:

sname	age
yuppy	35
rusty	35

Join Operation in Tuple Relational Calculus

Examples:

3. Find sailors rated > 7 who have reserved boat = 103.

Solution: $\{S \mid S \in \text{sailors} \wedge \text{s.rating} > 7 \wedge \exists R\ (R \in \text{reserves} \wedge \text{R.sid} = \text{s.sid} \wedge \text{R.bid} = 103)\}$

4. Find sailors rated > 7 who have reserved a red boat.

Solution: $\{S \mid S \in \text{sailors} \wedge \text{s.rating} > 7 \wedge \exists R\ (R \in \text{reserves} \wedge \text{R.sid} = \text{s.sid} \wedge \exists B(\text{ Boats} \wedge \text{B.bid} = \text{R.bid} \wedge \text{B.color} = \text{'Red'}))\}$

Division Operation in Tuple Relational Calculus

Examples

1. Find sailors who have reserved all boats.

Solution: $\{S \mid S \in \text{sailors} \wedge \forall B \in \text{boats } (\exists R \in \text{reserves (s.sid} = \text{R.sid} \wedge \text{B.bid} = \text{R.bid}))\}$

Domain Relational Calculus

1. Tuple relational and domain relational are semantically similar.
2. In *TRC*, tuples share an equal status as variables, and field referencing can be used to select tuple parts.

3. In *DRC* formed variables are explicit.
4. *DRC* query has the following form.
   $\{<x_1, x_2, \ldots x_n> / P(<x_1, x_2, \ldots, x_n>\}$
   Result included all tuples $<x_1, x_2, \ldots x_n>$
   That make the formula $p(<x_1, x_2, \ldots x_n>)$ true.
5. Formula given in *DRC* is recursively defined. First start with simple atomic formula and expand the formulas by using the logical connectives.
6. A variable that is not bound is free.
7. The variable $X_1, X_2, \ldots, X_n$ that appear in the left side of '/' must be the only free variable in the formula $p(\ldots)$.

Example: Consider the employee table given in the above Example.
The use of quantifiers $\exists x$ and $\forall x$ in a formula is said to bind x

Query 1: Display the Employees whose salary is above 2000?

$$\{<I, F, L, S>/<I, F, L, S> \in \text{Employee} \wedge S > 2000\}$$

Query 2: Display the EIds of Employees, whose salary is above 1000 and below 3000?

$$\{<I>/\exists F, L, S(<I, F, L, S> \in \text{Employee} \wedge (S > 1000 \wedge S < 3000))\}$$

SQL (Structured Query Language)

When a user wants to get some information from a database file, he/she can issue a query. A query is a user-request to retrieve data (or) information with a certain condition. SQL is a query language that allows user to specify the conditions (instead of algorithms)

Concept of SQL

The user specifies a certain condition. The program will go through all the records in the database file and select those records that satisfy the condition. The result of the query will be stored in the form of a table.

Features of SQL

1. SQL is a language of database. It includes database creation, deletion, fetching rows and modifying rows.
2. SQL is a structured query language for storing, manipulating and retrieving data stored in relational database.
3. It allows users to describe the data.
4. It allows users to create and drop database and tables.
5. It allows users to create view, functions in a database.
6. Allows users to set permissions on tables and views.
7. The standard SQL commands to interact with relational database are CREATE, SELECT, UPDATE, INSERT, DROP and DELETE.
8. The commands can be classified as follows:
   - *Data query language*: SELECT – It retrieves particular rows which satisfies the given condition.
   - *Data definition language*: CREATE, ALTER, DROP.
   - *Data manipulation language*: INSERT, UPDATE, DELETE

Features

1. Strong data protection
2. Robust transactional support
3. High performance
4. High availability
5. Security and flexibility to run anything
6. Easy to manage
7. User friendly

General Structure

SELECT ... FROM ... WHERE
SQL is divided into two languages

1. DML (data manipulation language)
   SELECT: Extracts data from a database table.
   UPDATE: Updates data in a database table.
   DELETE: Deletes data from a database table.
   INSERT INTO: Inserts new data into database table.
2. DDL (data definition language)
   CREATE TABLE - creates a new database table.
   ALTER TABLE - Alters a database table.
   DROP TABLE - deletes a database table.
   CREATE INDEX - Creates an index (search key).
   DROP INDEX - Deletes an index.
   RENAME – Changes the name of the table.

Types of keys:

1. Candidate key
2. Primary key
3. Super key
4. Foreign key
5. Composite primary key

In relational database, 'keys' play a major role. Keys are used to establish and identify relation between relations (or) tables.

Keys are used to ensure that each record within a table can be uniquely identified by combining one or more fields (or) column headers within a table.

Candidate key: A candidate key is a column or set of columns in a table that contains unique values, with these we can uniquely identify any database record without referring to any other columns data.

Each table may have one or more candidate keys, among the available candidate keys, one key is preserved for primary key.

A candidate key is a subset of a super key.

Example: Student

StudentId	First name	Last name	Course Id
CS00345	Jim	Black	C2
CS00254	Carry	Norris	C1
CS00349	Peter	Murray	C1
CS00196	John	Mc Cloud	C3
CS00489	Brat	Holland	C4
CS00553	Mary	Smith	C5

In the above table, we have studentId that uniquely identifies the students in a student table. This would be a candidate key.

In the same table, we have student's first name and last name, which are also candidate keys.

1. If we combine first name and last name then also it becomes a candidate key.
2. Candidate key must (have)
   - Unique values
   - No null values
   - Minimum number of fields to ensure uniqueness.
   - Uniquely identify each record in the table.
3. The candidate keys which are not selected for primary key are known as secondary keys or alternative keys.

Primary key: A primary key is a candidate key that is most suitable (or) appropriate to become main key of the table.

1. It is a special relational database table column ((or) combination of columns)
2. Primary key main features are
   - It must contain a unique value for each row of data.
   - It cannot contain null values.

Example: We can choose primary key as studentId which is mentioned in the table given in above example.

Composite primary key: A key that consists of two or more attributes that uniquely identify an entity is called *composite key* or *composite primary key.*

Example: Customer

Cust-Id	Order-Id	Sale-details
C1	O – 2	Sold
C1	O – 3	Sold
C2	O – 2	Sold
C2	O – 3	Sold

Composite primary key is {cust-Id, order-Id}

Super key: A super key is a combination of attributes that can be uniquely used to identify a database record. A table can have any number of super keys.

1. Candidate key is a special subset of super keys.

Example: Customer

Customer name	Customer Id	SSN	Address	DOB

Assume that we can guarantee uniqueness only for SSN field, then the following are some of the super keys possible.

1. {Name, SSN, DOB}
2. {ID, Name, SSN}

In a set of attributes, there must be at least one key (could be primary key or candidate key)

Foreign key: A foreign key is a column or group of columns in a relational database table that provides connectivity between data in two tables.

1. The majority of tables in a relational database system adhere to the concept of foreign key.
2. In complex databases, data must be added across multiple tables, thus the link or connectivity has to be maintained among the tables.
3. The concept of Referential Integrity constraint is derived from Foreign key.

Example: Emp

EId	EName	Dept – No

Dept

Dept-No	DName

In the above specified tables, Dept-No is common to both the tables, In Dept table it is called as primary key and in Emp table it is called as *foreign key*.

These two tables are connected with the help of 'Dept-No' field

1. For any column acting as a foreign key, a corresponding value should exist in the link (or) connecting table.
2. While inserting data and removing data from the foreign key column, a small incorrect insertion or deletion destroys the relationship between the two tables.

SQL Commands

SELECT statement

The most commonly used SQL command is SELECT statement. The SQL SELECT statement is used to query or retrieve data from a table in the database. A query may retrieve information from specified columns or from all of the columns in the table. To create a simple SQL SELECT statement, you must specify the column(s) names and the table name.

Syntax: SELECT column-name (s) from table name

Example: Persons

Lastname	Firstname	Address	City
Hansen	Ola	SpRoad,-20	Hyd
Svendson	Tove	GPRoad,-18	Secbad
Petterson	Kari	RpRoad,-19	Delhi

1. SELECT lastname FROM persons

   Output:

Lastname
Hansen
Svendson
Petterson

2. SELECT lastname, firstname FROM persons

Output:

Lastname	Firstname
Hansen	Ola
Svendson	Tove
Petterson	Kari

DISTINCT statement

Returns distinct values. It eliminates duplicate values.

Syntax: Select DISTINCT column_name (s) from table-name

Example: Orders

Company	Order.No
IBM	3412
DELL	5614
WIPRO	4412
DELL	4413

1. SELECT company FROM orders

Output:

Company
IBM
DELL
WIPRO
DELL

2. SELECT DISTINCT company FROM orders

Company
IBM
DELL
WIPRO

WHERE statement

The WHERE clause is used when you want to retrieve specific information from a table excluding other irrelevant data. By using WHERE clause, we can restrict the data that is retrieved. The condition provided in the WHERE clause filters the rows retrieved from the table and gives only those rows which were expected. WHERE clause can be used along with SELECT, DELETE, UPDATE statements.

The WHERE clause is used to specify a selection condition. All conditions are specified in this clause.

Syntax: SELECT column FROM table WHERE column operator value.

Operates used in where clause:
=
< > (not equal) (or) ! =
>
<
> =
< =
BETWEEN - Between an inclusive range.
LIKE - Search for a pattern

Example: Persons

Lastname	Firstname	Address	City	Year
Hansen	Ola	SPRoad, 16	Hyd	1956
Svendson	Tiva	GPRoad, 18	Sec	1977
Smith	Ole	RPRoad, 19	Hyd	1986
Petterson	Kari	SPRoad, 17	Sec	1985

1. SELECT * FROM persons
   Output: It displays the entire table

   2. SELECT * FROM persons WHERE city = 'Hyd'

   Output:

Lastname	Firstname	Address	City	Year
Hansen	Ola	SPRoad, 16	Hyd	1956
Smith	Ole	RPRoad, 19	Hyd	1986

LIKE condition

The LIKE operator is used to list all rows in a table whose column values match a specified pattern. It is useful when you want to search rows to match a specific pattern, or when you do not know the entire value. For this purpose, we use a wildcard character '%'.

The LIKE condition is used to specify a search for a pattern in a column.

A '%' sign can be used to define wildcards (missing letters in the pattern) both before and after the pattern.

Syntax: SELECT column FROM table WHERE column LIKE pattern

1. SELECT * FROM persons WHERE Firstname LIKE 'O%'

Solution: SQL statement will return persons with first names that start with a letter '*O*'

Output:

Lastname	Firstname	Address	City	Year
Hansen	Ola	SPRoad, 16	Hyd	1956
Smith	Ole	RPRoad, 19	Hyd	1986

2. SELECT * FROM persons WHERE Firstname LIKE '%a'

Solution: SQL statement will return persons whose first name ends with letter 'a'.

Output:

Last name	First name	Address	City	Year
Hansen	Ola	SPRoad, 16	Hyd	1956
Svendson	Tiva	GPRoad, 18	Sec. bad	1977

3. SELECT * FROM persons WHERE firstname LIKE '%la%'

Solution: SQL statement returns persons whose firstname contains 'la'. The word sequence 'la' may come at any place in the word.

Output:

Last name	First Name	Address	City	Year
Hansen	Ola	SPRoad, 16	Hyd	1956

String operations

1. '%idge%' matches 'Rockridge', 'Ridgeway', 'Perryridge'.
2. '______' matches a string of three characters.
3. '______%' matches a string of at least rhree characters.

INSERT INTO statement

This statement is used to insert new rows into a table. While inserting a row, if you are adding values for all the columns of the table you need not specify the column(s) name in the SQL query. But you need to make sure the order of the values is in the same order as the columns in the table. When adding a row, only the characters or data values should be enclosed with single quotes and ensure the data type of the value and the column matches. One can specify the columns for which you want to insert data

Syntax: INSERT INTO table-name (column1, column2 ...) VALUES (value 1, value2 ...)

1. INSERT INTO persons VALUES ('Hetland', 'Camilla', 'HPRoad 20', 'Hyd')

Output:

Last name	First Name	Address	City
Hansen	Ola	S.P Road 16	Hyd
Svesdon	Tiva	GP Road 18	Secbad
Smith	Ole	RP Road 19	Hyd
Petterson	Kari	SP Road 17	Secbad
Hetlan	Camilla	HPRoad, 20	Hyd

2. Insert data into specified columns
   INSERT INTO persons (Lastname, Address) VALUES ('Rasmussen', 'street 67')

Output:

Last name	First Name	Address	City
Hansen	Ola	SP Road 16	Hyd
Svesdon	.Tiva	GP Road 18	Secbad
Smith	Ole	RP Road 19	Hyd
Petterson	Kari	SP Road 17	Secbad
Hetlan	Camilla	HP Road 20	Hyd
Rasmussen		Street 67	

UPDATE

The update statement is used to modify the data in a table.

Syntax: UPDATE table_name
SET Column_name = new_value
WHERE column_name = some_value.

1. Add a first name (Nine) to the person whose last name is 'Rasmussen'?

Solution: UPDATE person SET Firstname = 'Nine' WHERE Lastname = 'Rasmussen'

2. Change the address and add the name of the city as Hyd of a person with last name Rasmussen?

Solution: UPDATE person
SET Address = 'street 12',
city = 'Hyd'
WHERE Lastname = 'Rasmussen'

DELETE statement

The DELETE statement is used to delete rows from a table. The WHERE clause in the SQL delete command is optional, and it identifies the rows in the column that gets deleted. If you do not include the WHERE clause, all the rows in the table will be deleted.

Syntax: DELETE FROM table_name
WHERE column_name = some_value

1. Delete all rows?

Solution: DELETE * FROM table_name

Cartesian product

The Cartesian product of two sets is the set of all ordered pairs of elements such that the first element in each pair belongs to the first set and the second element in each pair belongs to the second set. It is denoted by cross(X).

For example, given two sets:

$S1 = \{1, 2, 3\}$ and $S2 = \{4, 5, 6\}$

The Cartesian product $S1 \times S2$ is the set

$\{(1, 4), (1, 5), (1, 6), (2, 4), (2, 5), (2, 6), (3, 4), (3, 5), (3, 6)\}$

Example:

Female	
Name	Job
Komal	Clerk
Ankita	Sales

Male	
Name	Job
Rohit	Clerk
Raju	Sales

Assume that the tables refer to male and female staff, respectively. Now, in order to obtain all possible inter-staff marriages, the cartesian product can be taken.

Male-Female

Female name	Female job	Male name	Male job
Komal	Clerk	Rohit	Clerk
Komal	Clerk	Raju	Sales
Ankita	Sales	Rohit	Clerk
Ankita	Sales	Raju	Sales

Examples:

1. Find the Cartesian product of borrower and loan?

Solution: SELECT * FROM borrower, loan

2. Find the name, loan-no, and loan amount of all customers having a loan at the Perryridge branch?

Solution: SELECT customer_name, borrower. loan_ number, amount FROM borrower, loan WHERE borrower. loan-no = Loan.loan_no AND branch_name = 'perryridge'

3. Find all loan numbers for loans made at the perryridge branch with loan amount greater than 1200?

Solution: SELECT loan-no FROM loan WHERE branch. name = 'perryridge' AND amount > 1200

Comparison operator

Relation algebra includes six comparison operators (=, < >, <, >, < =, > =). These are proposition forming operators on terms. For example, $x <> 0$ asserts that x is not equal to 0. It also includes three logical operators (AND, OR, NOT). These are proposition forming operators on propositions.

Example: $x > 0$ and $x < 8$
Comparison results can be combined using the logical connections AND, OR NOT

1. Find the loan-no of those loans with amounts between 90,000 and 1,00,000?

Solution: SELECT loan-no FORM loan WHERE amount BETWEEN 90,000 AND 1,00,000. SQL allows renewing relations and attributes using 'AS' clause

2. Find the name, loan-no and loan amount of all customers, rename the column name loan-no as loan.id?

Solution: SELECT customer.name, borrower.loan no AS loan.id, amount FROM borrower, loan, WHERE borrower. loan-no = loan.loan-no

Ordering of Tuples

It lists the tuples in alphabetical order.

Example: List in alphabetic order, the names of all customers having a loan in Perryridge branch?

Solution: SELECT customer-name FROM borrower WHERE branch.name = 'perryridge' ORDERBY customer-name

We may specify 'desc' for descending order (or) 'asc' for ascending order. - 'asc' is default.

Example: ORDERBY customer-name desc.

Join (⋈)
SQL Join is used to get data from two (or) more tables, which appear as single table after joining.

1. Join is used for combining columns from two or more tables by using values common to both tables.
2. Self Join: A table can also join to itself is known as self join. Types of JOIN
   1. INNER JOIN
   2. OUTER JOIN
      (i) LEFT OUTER JOIN
      (ii) RIGHT OUTER JOIN
      (iii) FULL OUTER JOIN

1. INNER JOIN (or) EQUI JOIN

It is a simple JOIN in which result is based on matching tuple, depending on the equality condition specified in the query.

Syntax: SELECT Column-names FROM table name1 INNER JOIN table name 2 WHERE table name 1. Column name = table name 2.column – name.

Example: Class

SID	Name
11	Ana
12	Bala
13	Sudha
14	adam

Info

SID	City
11	Bangalore
12	Delhi
13	Hyderabad

SELECT *
FROM Class INNER JOIN Info
WHERE Class.SID = Info.SID

Result:

SID	Name	SID	City
11	Ana	11	Banglore
12	Bala	12	Delhi
13	Sudha	13	Hyderabad

NATURAL JOIN:
NATURAL JOIN is a type of INNER JOIN which is based on column having same name and same data type present in two tables on which join is performed.

Syntax: SELECT *
FROM table-name1 NATURAL JOIN table-name 2

Example: Consider the tables class and Info, and the following Query

SELECT *
FROM class NATURAL JOIN Info

Result:

SID	Name	City
11	Ana	Bangalore
12	Bala	Delhi
13	Sudha	Hyderabad

Both tables being joined have SID column (same name and same data type), the tuples for which value of SID matches in both the tables, appear in the result.

Dangling tuple: When NATURAL JOIN is performed on two tables, there would be some missing tuples in the result of NATURAL JOIN

Those missing tuples are called *Dangling tuples*. In the above example, the number of dangling tuples is 1 that is

14	Adam

OUTER JOIN: Outer Join is based on both matched and unmatched data.

LEFT OUTER JOIN: Left outer Join returns the tuples available in the left side table with the matched data of 2 tables and null for the right tables column.

Example: Consider the table's class and Info

SELECT *
FROM class LEFT OUTER JOIN Info
ON(class.SID = Info. SID)

Result:

SID	Name	City
11	Ana	Banglore
12	Bala	Delhi
13	Sudha	Hyderabad
14	adam	NULL

RIGHT OUTER JOIN: RIGHT OUTER JOIN returns the tuples available in the Right side table with the matched data of 2 tables and NULL for the left table's column.

Example: Class 1

SID	Name
16	Arun
17	Kamal

Info 1

SID	City
16	Chennai
17	Noida

Query:

SELECT *
FROM Class1 RIGHT OUTER JOIN Info1
ON(class1.SID = Info1.SID)

Result:

SID	Name	City
16	Arun	Chennai
18	NULL	Noida

FULL OUTER JOIN: The full outer Join returns the tuples with the matched data of two tables, remaining rows of both left table and Right table are also included.

Example: Consider the tables class 1 and Info1

Query:

SELECT *
FROM class1 FULL OUER JOIN Info1
ON(class1.SID = Info1.SID)

Result:

SID	Name	City
16	Arun	Chennai
17	Kamal	NULL
18	NULL	Noida

ALTER command: ALTER command is used for altering the table structure

1. It is used to add a new column to existing table.
2. To rename existing column.
3. ALTER is used to drop a column.
4. It is used to change data type of any column or modify its size.

Add new column: By using alter command, we can add a new column to the table.

Syntax: ALTER table table-name ADD(column-name data type).

Example: Consider a student table.

SID	S Name	Grade

Add a new column called address

```
ALTER table student ADD (address char);
```

Example: Add multiple columns, parent-name, course-Name, date-of-birth to student table.

```
ALTER table student ADD (parent-name
varchar(60), course-Name varchar(20),
date-of-birth date);
```

Example: Change the data type of column address to varchar?

```
ALTER table student modify(address varchar(30))
```

Example: Rename a column address to Location

```
ALTER table student rename address to Location
```

TRUNCATE command: Truncate command removes all tuples from a table, this command will not destroy the tables structure.

Syntax: Truncate table table-name

DROP Command: DROP query removes a table completely from database. This command will destroy the table structure.

Syntax: Drop table table-name

Rename: This command is used to rename a table.

Syntax: Rename table old-table-name to new-table-name.

Example: Rename table Employee to New-Employee.

DROP a column: Alter command can be combined with DROP command to remove columns from a table.

Syntax: alter table table-name DROP(column-name)

Example: Alter table student DROP (grade)

Exercises

Practice Problems I

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider the given table called *Persons*

P-Id	Lastname	Firstname	Address	City
1	Hansen	ola	Timoteivn -10	Sandnes
2	Svendson	Tove	Brazil-50	Sandnes
3	Petterson	Kari	Storgt-20	Stavanger
4	Joseph	ole	Brazil-20	Sandnes

Write a query to select the persons with first name 'Tove' and last name 'Svendson'?

(A) SELECT *
FROM Persons
WHERE first-name='tove'
AND last-name='svendson'

(B) SELECT *
FROM Persons
WHERE first-name='tove'
OR last-name='svendson'

(C) SELECT first-name
FROM Persons
WHERE first-name='tove'
AND last-name='svendson'

(D) SELECT last-name
FROM Persons
WHERE first-name='tove'
AND last-name='svendson'

2. Write a query to select only the persons with last name 'Svendson' and the first name equal to 'Tove' or 'ola'?

(A) SELECT *
FROM Persons
WHERE last-name='svendson'
AND first-name='tove'

(B) SELECT *
FROM Persons
WHERE last-name='svendson'
AND (first-name='tove' OR first-name='ola')

(C) SELECT *
FROM Persons
WHERE last-name='svendson'
AND (first-name='tove' AND first-name='ola')

(D) SELECT *
FROM Persons
WHERE last-name='svendson'
OR (first-name='tove' AND first-name='ola')

3. Write an SQL statement to add a new row, but only in specified columns, for the persons table add data into columns 'P-Id', 'Last name' and the 'First name' with values (5, Teja, Jakob)?

(A) INSERT INTO Persons VALUES(5,'teja','jakob')
(B) INSERT INTO Persons VALUES(5,teja,jakob)
(C) INSERT INTO Persons (P-Id, last-name, first-name) VALUES(5,'teja','jakob')
(D) INSERT INTO Persons(P-Id, last-name, first-name) VALUES(5,teja,jakob)

4. Write an SQL statement:

(i) To select the persons living in a city that starts with 'S' from the 'Persons' table?

(A) SELECT *
FROM Persons
WHERE city LIKE 's__'.

(B) SELECT *
FROM Persons
WHERE city LIKE 's%'.

(C) SELECT *
FROM Persons
WHERE city LIKE '%s'.

(D) SELECT *
FROM Persons
WHERE city LIKE '_s%'.

(ii) To select the persons living in a city that contains the pattern 'tav' from 'Persons' table?

(A) SELECT *
FROM Persons
WHERE city LIKE '_tav_'.

(B) SELECT *
FROM Persons
WHERE city LIKE '_tav%'.

(C) SELECT *
FROM Persons
WHERE city LIKE '%tav_'.

(D) SELECT *
FROM Persons
WHERE city LIKE '%tav%'.

(iii) To select the persons whose last name starts with '*b*' or '*s*' or '*p*' ?

(A) SELECT *
FROM Persons
WHERE last-name LIKE '*b-s-p*'

(B) SELECT *
FROM Persons
WHERE last-name LIKE '*b%s%p*'

(C) SELECT *
FROM Persons
WHERE last-name LIKE '*b%s%p%*'

(D) SELECT *
FROM Persons
WHERE last-name LIKE '[*bsp*]%'

5. Consider the given table called 'Persons'

P-Id	Last-name	First-name	Address	City
1	Hansen	ola	Timoteivn-10	Sandnes
2	Svendson	Tove	Brazil-50	Sandnes
3	Petterson	Kari	Storgt-20	Stavanger

and the 'Orders' table

O-Id	Order No	P-Id
11	77895	3
12	44678	3
13	22456	1
14	24562	1
15	34764	5

perform NATURAL JOIN operation on both the tables and what is are the O_Id's displayed in the result?

(A) 11, 12, 13 (B) 11, 13, 14
(C) 11, 12, 13, 14 (D) 12, 13, 14

6. Write an SQL to perform FULL JOIN operation on both 'Person' and 'Orders' tables and What is the number of tuples in the Result?

(A) 4 (B) 5
(C) 6 (D) 7

7. Consider the given table 'Result'.

Student Name	Marks
A	55
B	90
C	40
D	80
E	85
F	95
G	82

(i) Find out the students who have scored more than 80 marks, and display them in descending order according to their marks?

(A) SELECT student-name,marks
FROM Result
WHERE marks > 80
ORDERBY marks DESC

(B) SELECT *
FROM Result
WHERE marks > 80
ORDERBY marks DESC

(C) SELECT student-name,marks
FROM Result
WHERE marks > 80
ORDERBY marks

(D) (A) and (B)

(ii) From the above table, find out the top-most three students.

(A) SELECT student-name
FROM Result
ORDERBY marks DESC > 3

(B) SELECT student-name
FROM Result
ORDERBY marks DESC = 3

(C) SELECT student-name
FROM Result
ORDERBY marks DESC limit 3

(D) None of these

8. From the table 'Results', Identify the suitable SQL expression?

(i) Find out the student Who stood 2nd?

(A) SELECT student-name
FROM Result
ORDERBY marks DESC limit 2

(B) SELECT student-name
FROM Result
ORDERBY marks DESC limit 1,1

(C) SELECT student-name
FROM Result
ORDERBY marks DESC limit 1,2

(D) SELECT student-name
FROM Result
ORDERBY marks DESC limit 2,1

(ii) Find out how many students scored > = 80.

(A) SELECT COUNT(*)
FROM Result
WHERE marks > = 80

(B) SELECT COUNT
FROM Result
WHERE marks > = 80

(C) SELECT SUM(*)
FROM Result
WHERE marks > = 80

(D) SELECT SUM
FROM Result
WHERE marks > = 80

9. Consider the given tables:

Customer

Customer name	Customer street	Customer city
Sonam	Mirpurroad	Dhaka
Sonam	Aga KhaRoad	Bogra
Anusha	XYZRoad	Kanchi
Nandy	MirpurRoad	Dhaka

Account

Account number	Customer name	Balance
A-101	Anusha	1000
A-102	Anusha	1500
A-103	Sonam	2000
A-104	Nandy	2500

From the customer table, find out the names of all the customers who live in either Dhaka or Bogra?

(A) SELECT customer-name
FROM customer
WHERE customer-city='dhaka' OR customer-city='bogra'

(B) SELECT customer-name
FROM customer
WHERE customer-city=dhaka OR customer-city='bogra'

(C) SELECT customer-name
FROM customer
WHERE customer-city='dhaka' AND customer-city='bogra'

(D) SELECT customer-name
FROM customer
WHERE customer-city='dhaka' EXIST customer-city='bogra'

10. Consider the given tables

Loan

Loan Number	Branch Name	Amount
L-101	Dhaka	1000
L-103	Khulna	2000

Borrower:

Customer name	Loan number
Sonam	L-101
Nandy	L-103
Anusha	L-103

(i) What are the number of tuples present in the result of cross product of the above two tables?

(A) 4 (B) 5
(C) 6 (D) 7

(ii) Find the loan-numbers from loan table where branch-name is Dhaka?

(A) SELECT loan-number
FROM loan
WHERE branch-name='dhaka'

(B) SELECT loan-number
FROM branch-name='dhaka'

(C) SELECT loan-number
FROM Loan × Borrower

(D) Both (A) and (C)

11. (i) Find all customers who have only accounts but no loans.

(A) SELECT customer-name
FROM depositor LEFT OUTER JOIN Borrower ON
Depositor.customer-name=Borrower.customer-name
WHERE loan-number IS NULL

(B) SELECT customer-name
FROM depositor LEFT OUTER JOIN Borrower ON
Depositor.customer-name = Borrower.customer-name
WHERE loan-number=NULL

(C) SELECT customer-name
FROM depositor RIGHT OUTER JOIN Borrower ON
Depositor.customer-name=Borrower.customer-name
WHERE loan-number IS NULL

(D) SELECT customer-name
FROM depositor RIGHT OUTER JOIN Borrower ON
Depositor.customer-name=Borrower.customer-name
WHERE loan-number=NULL

(ii) Find the names of all customers who have either an account or loan but not both.

Borrower

Customer name	Loan no.
Sonam	L-101
Sonam	L-102
Anusha	L-103

Depositor

Customer name	Account no.
Anusha	A-102
Sonam	A-103
Nandy	A-104

(A) SELECT customer name
FROM depositor FULL OUTER JOIN
Borrower ON
Depositor.customer-name=Borrower.customer-name
WHERE loan-number IS NULL OR Account-number=NULL

(B) SELECT customer-name
FROM depositor FULL OUTER JOIN
Borrower ON
Depositor.customer-name = Borrower.customer-name
WHERE loan-number IS NULL OR Account-number IS NULL

(C) SELECT customer-name
FROM depositor FULL OUTER JOIN
Borrower ON
Depositor.customer-name = Borrower.customer-name
WHERE loan-number = NULL OR Account-number = NULL

(D) SELECT customer-name
FROM depositor FULL OUTER JOIN Borrower ON
Depositor.customer-name = Borrower.customer-name
WHERE loan-number=NULL OR Account-number IS NULL

12. Consider the following 'employee' table

Employee name	Branch name	Branch city	Salary
A	DU	Dhaka	1000
B	DU	Dhaka	2000
C	BUET	Dhaka	3000
D	KUET	Khulna	4000
E	KU	Khulna	5000
F	RU	Rajshahi	6000

(i) Find the distinct number of branches appearing in the employee relation.

(A) SELECT COUNT(branch-name)
FROM Employee

(B) SELECT COUNT(DISTINCT branch-name)
FROM Employee

(C) SELECT DISTINCT COUNT(branch-name)
FROM Employee

(D) SELECT COUNT(*)
FROM Employee

(ii) Find the total salary of all employees at each branch of the bank.

(A) SELECT branch-name, SUM(salary)
FROM Employee
GROUP BY Branch-city

(B) SELECT branch-name, SUM(salary)
FROM Employee
GROUP BY Branch-name

(C) SELECT SUM(salary)
FROM Employee
GROUP BY Branch-name

(D) SELECT branch-name, SUM(salary)
FROM Employee

(iii) Find branch city, branch name Wise total salary, average salary and also number of employees.

(A) SELECT branch-city, branch-name,
SUM (salary), AVG(salary),
COUNT (Employee-name)
FROM Employee
GROUP BY branch-city, branch-name

(B) SELECT branch-city, branch-name,
SUM (salary), AVG (salary),
COUNT (Employee-name)
FROM Employee
GROUP BY branch-city

(C) SELECT branch-city, branch-name,
SUM (salary), AVG (salary), COUNT (Employee-name)
FROM Employee
GROUP BY branch-name

(D) SELECT branch-name, SUM (salary),
AVG (salary), COUNT (Employee-name)
FROM Employee
GROUP BY branch-city, branch-name

Common data for questions 13 to 15: Consider the SHIPMENTS relation and write the SQL statements for the below

SUPPLIERS

Supplier number	Supplier name	Status	City
SN1	Suma	30	Hyderabad
SN2	Hari	20	Chennai
SN3	Anu	10	Hyderabad
SN4	Mahesh	20	Bombay
SN5	Kamal	30	Delhi

PARTS

Part number	Part name	Color	Weight	City
PN1	X	Red	13.0	Chennai
PN2	Y	Green	13.5	Bombay
PN3	X	Yellow	13.2	Hyderabad
PN4	Y	Green	14.1	Calcutta
PN5	Z	Red	14.3	Hyderabad
PN6	Z	Blue	14.2	Bombay

PROJECT

Project number	Project name	City
PJ1	Display	Chennai
PJ2	OCR	Bombay
PJ3	RAID	Chennai
PJ4	SORTER	Hyderabad
PJ5	EDS	Chennai
PJ6	Tape	Bombay
PJ7	Console	Hyderabad

SHIPMENTS

Supplier number	Part number	Project number	Quantity
SN1	PN1	PJ1	300
SN1	PN1	PJ4	400
SN2	PN3	PJ1	350
SN2	PN3	PJ2	450
SN2	PN3	PJ3	640
SN2	PN3	PJ4	320
SN2	PN3	PJ5	330
SN2	PN3	PJ6	520
SN2	PN3	PJ7	480
SN2	PN5	PJ2	460
SN3	PN3	PJ1	440
SN3	PN4	PJ2	410
SN4	PN6	PJ3	310
SN4	PN6	PJ7	320
SN5	PN2	PJ2	340
SN5	PN2	PJ4	350
SN5	PN5	PJ5	360
SN5	PN5	PJ7	370
SN5	PN6	PJ2	380
SN5	PN1	PJ4	420
SN5	PN3	PJ4	440
SN5	PN4	PJ4	450
SN5	PN5	PJ4	400
SN5	PN6	PJ4	410

13. (i) For each part supplied, get the part number and the total shipment quantity?

(A) SELECT shipments.part-number, SUM (shipments.quantity)
FROM Shipments
GROUP BY shipments.part-number

(B) SELECT SUM(shipments.quantity)
FROM Shipments
GROUP BY shipments.part-number

(C) SELECT shipments.part-number, SUM (shipments.quantity)
FROM Shipments
GROUP BY shipments.quantity

(D) SELECT shipments.part-number, SUM (shipments. part-number)
FROM Shipments
GROUP BY shipments.part-number

(ii) Get part numbers for parts supplied by more than two suppliers?

(A) SELECT shipments.part-number
FROM Shipments
GROUP BY shipments.part-number
HAVING COUNT(shipments.supplier-number) > 2

(B) SELECT shipments.part-number
FROM Shipments
GROUP BY shipments.part-number
HAVING COUNT(shipments.supplier-number)>=2

(C) SELECT shipments.part-number
FROM Shipments
GROUP BY shipments.part-number>2

(D) SELECT shipments.part-number, COUNT (shipments.supplier-number)>2
FROM Shipments
GROUP BY shipments.part-number

(iii) Get supplier names for suppliers who supply part PN3?

(A) SELECT DISTINCT suppliers.supplier-name
FROM Supplier
WHERE suppliers.supplier-number IN (SELECT Shipments.supplier-number
FROM Shipments
WHERE Shipments.part-number='PN3')

(B) SELECT DISTINCT suppliers.supplier-name
FROM Supplier
WHERE suppliers.supplier-number NOT IN(SELECT Shipments.supplier-number
FROM Shipments
WHERE Shipments.part-number='PN3')

(C) SELECT DISTINCT suppliers.supplier-name
FROM Supplier
WHERE suppliers.supplier-number EXCEPT (SELECT Shipments.supplier-number
FROM Shipments
WHERE Shipments.part-number='PN3')

(D) SELECT DISTINCT suppliers, supplier-name
FROM Supplier
WHERE suppliers.supplier-number
UNION
SELECT Shipments.supplier-number
FROM Shipments
WHERE Shipments.part-number='PN3'

14. (i) Get supplier names for suppliers who supply at least one blue part.

(A) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE suppliers.supplier-number
IN (SELECT Shipments.supplier-number
FROM Shipments
WHERE Shipments.part-number
IN (SELECT Parts.part-number
FROM Parts
WHERE Parts.color='Blue'))

(B) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE suppliers.supplier-number
IN (SELECT Shipments.supplier-number
FROM Shipments

WHERE Shipments.part-number NOT
IN(SELECT Parts.part-number
FROM Parts
WHERE Parts.color='Blue'))

(C) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE suppliers.supplier-number NOT
IN(SELECT Shipments.supplier-number
FROM Shipments
WHERE Shipments.part-number
IN (SELECT Parts.part-number
FROM Parts
WHERE Parts.color='Blue'))

(D) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE suppliers.supplier-number
IN (SELECT Shipments.supplier-name
FROM Shipments
WHERE Shipments.part-number
IN (SELECT Parts.part-number
FROM Parts
WHERE Parts.color='Blue'))

(ii) Get supplier numbers for suppliers with status less than the current maximum status in the suppliers table:

(A) SELECT Suppliers.supplier-number
FROM suppliers
WHERE Suppliers.status < (SELECT MAX (Suppliers.status)
FROM Suppliers)

(B) SELECT Suppliers.supplier-number
FROM suppliers
WHERE Suppliers.status<=(SELECT MAX (Suppliers.status)
FROM Suppliers)

(C) SELECT Suppliers.supplier-number,
MAX (Suppliers.status)
FROM suppliers
WHERE Suppliers.status

(D) SELECT Suppliers.supplier-number
FROM suppliers
WHERE Suppliers.status=MAX(Suppliers.status)

(iii) Get supplier names for suppliers who supply part PN2?

(A) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE EXIST(SELECT *
FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number='PN2')

(B) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE NOT EXIST(SELECT *
FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number='PN2')

(C) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE EXIST(SELECT *
FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
OR
Shipments.part-number='PN2')

(D) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE EXIST(SELECT *
FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
UNION
Shipments.part-number='PN2')

15. (i) Get supplier names for suppliers who do not supply part PN2.

(A) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE NOT EXIST(SELECT *
FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number='PN2')

(B) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE EXIST(SELECT *
FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number='PN2')

(C) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE EXCEPT(SELECT *
FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number='PN2')

(D) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE NOT EXIST(SELECT *
FROM Shipments

WHERE Shipments.supplier-number = suppliers.supplier-number
OR
Shipments.part-number='PN2')

(ii) Get supplier names for suppliers who supply all parts.

(A) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE NOT EXIST(SELECT *
FROM Part
WHERE NOT EXIST(SELECT * FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number=Parts.part-number))

(B) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE EXIST(SELECT *
FROM Part
WHERE NOT EXIST(SELECT * FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number=Parts.part-number))

(C) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE NOT EXIST(SELECT *
FROM Part
WHERE EXIST(SELECT * FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number=Parts.part-number))

(D) SELECT DISTINCT suppliers.supplier-name
FROM Suppliers
WHERE EXIST(SELECT *
FROM Part
WHERE EXIST(SELECT * FROM Shipments
WHERE Shipments.supplier-number = suppliers.supplier-number
AND
Shipments.part-number=Parts.part-number))

(iii) Get part numbers for parts that either weigh more than-16 pounds or are supplied by supplier *SN*3, or both?

(A) SELECT parts.part-number
FROM parts
WHERE Parts.weight>18
UNION
SELECT Shipments.part-number
FROM shipments
WHERE Shipments.supplier-number='SN2'

(B) SELECT parts.part-number
FROM parts
WHERE Parts.weight>18
UNION
SELECT Shipments.supplier-name
FROM shipments
WHERE Shipments.supplier-number='*SN*2'

(C) SELECT parts.part-number
FROM parts
WHERE Parts.weight>18
UNION
SELECT Shipments.part-number,Shipments.supplier-name
FROM shipments
WHERE Shipments.supplier-number='*SN*2'

(D) SELECT parts.part-Number, parts.color
FROM parts
WHERE Parts.weight>18
UNION
SELECT Shipments.part-number
FROM shipments
WHERE Shipments.supplier-number='*SN*2'

Common data for questions 16 and 17: Consider the following relation: Teach

Name	Address	course
Zohar	40B,east city	MD
Nisha	16/2, hyd	BDS
Zohar	40B, East city	MS
Ravi	New York	MBA

16. The teacher with name Zohar teaching the course MS?
(A) σ_{Name} = 'Zohar' teach = MS.
(B) π_{Name} = 'Zohar' teach = MS.
(C) σ_{name} = 'Zohar' and course = 'MS' (teach).
(D) π_{Name} = 'Zohar' and course = 'MS' (teach).

17. Select the names of courses taught by Zohar?
(A) $\pi_{\text{course}}(\sigma_{\text{Name} = \text{'Zohar'}}(\text{Teach}))$
(B) $\sigma_{\text{course}}(\pi_{\text{Name} = \text{'Zohar'}}(\text{Teach}))$
(C) $\pi_{\text{course}}(\sigma_{\text{Name} = \text{'MD'}}(\text{Teach}))$
(D) None

18. Consider the join of a relation *A* with a relation *B*. If *A* has *m* tuples and *B* has *n* tuples. Then the maximum and minimum sizes of the join respectively are.
(A) mn and $m + n$
(B) $m + n$ and $(m - n)$
(C) mn and m
(D) mn and 0

19. Match the following:

I	Set intersection	1	$R \mid\times\mid S$
II	Natural join	2	$r - (r - s)$
III	Division	3	$\leftarrow$
IV	Assignment	4	$\pi_{R-S}(r) - \pi_{R-S}$ $(\pi_{R-S}(r) \times s)$ $-\pi_{R-S}, s(r)$

(A) I – 2, II – 1, III – 4, IV – 3
(B) I – 3, II – 4, III – 2, IV – 1
(C) I – 1, II – 2, III – 3, IV – 4
(D) I – 2, II – 3, III – 4, IV – 1

20. Which one is correct for division operations for relation r and s

(A) $r \div s$
(B) $\pi_{R-S}(r) - \pi_{R-S}((\pi_{R-S}(r) \times s) - \pi_{R-S}), s(r)$
(C) Temp 1 $\leftarrow \pi_{R-S}(r)$
Temp 2 $\leftarrow \pi_{R-S}(\text{temp1} \times s) - \pi_{R-S}, s(r)$
result = temp 1 – temp 2
(D) All the above

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. The correct order of SQL expression is
(A) Select, group by, where, having
(B) Select, where, group by, having
(C) Select, group by, having, where
(D) Select, having, where, group by

2. Which one is not a query language?
(A) SQL (B) QBE
(C) Data log (D) MySQL

3. Like '*a b* \ % *c d*' escape '\' matches all the strings
(A) Ending with *a b c d*
(B) Beginning with *a b c d*
(C) Beginning with *a b c d*
(D) Beginning with *a b* % *c d*

4. '_ _ _%' matches any string of
(A) At least three characters
(B) At most three characters
(C) Exactly three characters
(D) exactly three characters ending with %

5. Which of the following are set operations?
(i) Union
(ii) Intersection
(iii) Set Difference
(iv) Cartesian Product
(A) (i), (ii), (iii)
(B) (i), (iii), (iv)
(C) (i), (iii), (ii), (iv)
(D) (i), (ii), (iv)

6. What is the purpose of project operation?
(A) It selects certain columns
(B) It selects certain rows
(C) It selects certain strings
(D) It selects certain integers

Common data for questions 7 and 8: Person

Id	Name	Age	Hobby
11	Anu	21	Stamp Collection
22	Kamal	32	Painting
33	Ravi	24	Dancing
44	Ram	22	Singing

7. Select the persons whose hobby is either painting (or) singing.
(A) $\sigma_{\text{Hobby = 'painting' OR Hobby = 'singing'}}$ (person)
(B) $\sigma_{\text{Hobby = 'painting',' singing'}}$ (person)
(C) $\sigma_{\text{Hobby = 'painting' OR 'singing'}}$ (person)
(D) All are correct

8. Select the persons whose age is above 21 and below 32:
(A) $\sigma_{\text{age > 21 AND age < 32}}$ (person)
(B) $\sigma_{21 < \text{age} < 32}$ (person)
(C) $\sigma_{\text{age > 21 OR age < 32}}$ (person)
(D) $\sigma_{\text{age < 21 AND age > 32}}$ (person)

Common data for questions 9 and 10: Consider the following relation: Teach

Name	course	Rating	Age
Zohar	MD	7	35
Nisha	BDS	8	27
Zohar	MS	7	34
Ravi	MBA	9	33

9. Select the teachers whose rating is above 7 and whose age is less than 32?
(A) $s_{\text{Rating > 7 AND Age < 32}}$ (Teach)
(B) $s_{\text{Rating} \geq \text{7 AND Age < 32}}$ (Teach)
(C) $s_{\text{Rating > 7 AND < 32}}$ (Teach)
(D) Both (A) and (B)

10. Select the courses with rating above 7?
(A) $\pi_{\text{course}}(\sigma_{\text{rating > 7}}(\text{Teach}))$
(B) $\sigma_{\text{course}}(\pi_{\text{rating > 7}}(\text{Teach}))$
(C) $\pi_{\text{name, course}}(\sigma_{\text{rating > 7}}(\text{Teach}))$
(D) None

Common data for questions 11 and 12: Consider the following schema of a relational database employee (<u>empno</u>, ename, eadd) project (<u>pno</u>, pname) Work–on (empno, pno) Part(<u>partno</u>, partname, qty-on-hand, size) Use (empno, pno, partno, number)

11. Display the names of the employees who are working on a project named 'VB'.
(A) $\sigma_{\text{name}}(\text{employee} \bowtie (\sigma_{\text{pname = 'VB'}}\ \text{project}) \bowtie \text{worked on})$
(B) $\sigma_{\text{name}}(\text{employee} \bowtie (\pi_{\text{pname = 'VB'}}(\text{project}) \bowtie \text{work on})$
(C) $\pi_{\text{name}}(\text{employee} \bowtie (\sigma_{\text{pname = 'VB'}}(\text{project}) \bowtie \text{work on})$
(D) $\pi_{\text{name}}(\text{employee} \bowtie (\pi_{\text{pname}} = \text{'VB'}(\text{project}) \bowtie \text{work on})$

12. Display the names of the people who are not working for any project.

(A) π_{name} (employee ⋈(π_{name} (employee + work on)

(B) π_{name} (employee – π_{name} (employee ∩ work on)

(C) π_{name} (employee – π_{name} (employee ⋈ work on)

(D) σ_{name} (employee – σ_{name} (employee ⋈ work on)

13. Consider the following tables:

A	B	C	D
b	c	e	f
a	b	i	j
b	c	g	h
b	c	a	d
d	i	g	h
d	j	j	k
d	i	e	f

C	D
e	f
g	h

R ÷ S

A	B
b	c
d	i

Which of the following statements is true?

(A) $R \div S = p_{A,B}(R) - p_{A,B}(p_{A,B}(R) \times S + R)$

(B) $R \div S = p_{A,B}(R) - p_{A,B}(p_{A,B}R \times S - R)$

(C) $R \div S = p_{A,B}(R) - p_{A,B}((p_{A,B}(R) \times S) - R)$

(D) $R \div S = p_{A,B}(R) - p_{A,B}(p_{A,B}(R) \times R - S)$

Common data for questions 14 and 15: Consider the following schema of a relational data base
student (sno, name, address)
project (pno, Pname) work-on (sno, pno)
Part (part no, part name, qtyon hand size)
Use (sno, pno, part no, number)

14. List the names of the students who are participating in every project and have used every part.

(A) σ_{name}(student ⋈(((Workon) ÷ σ_{pro}(project)) ∩ ($\sigma_{sno,\ part\ no}$(use) ÷ $\sigma_{part\ no}$ (part)))

(B) π_{name}(student ⋈(((Workon) ÷ π_{pro}(project)) ∩ ($\pi_{sno,\ partno}$(use) ÷ $\sigma_{part\ no}$ (part)))

(C) π_{name}(student ⋈(((Workon) ÷ π_{partno} (project)) ∩ ($\pi_{sno,\ partno}$(use) ÷ $\sigma_{part\ no}$ (part)))

(D) π_{name}(student ∞ (((Workon) ÷ π_{pro}(project)) ∪ ($\pi_{ssno,\ partno}$ (use) ÷ $\pi_{part\ no}$ (part)))

15. The following query gives π_{name} (employee ⋈(work on ÷ π_{pro} ($\sigma_{Pname\ =\ 'MS'\ AND\ 'MD'}$(project)))

(A) Names of the students who are working in either projects 'MS' or 'MD'

(B) Names of the students who are working in both the projects 'MS' or 'MD'

(C) Names of the students who are not working in any of the projects 'MS' or 'MD'

(D) None of the above

16. 'All rows corresponding to students whose sno's are between 10 and 20

(i) Select * form student where SNo are between 5 AND 10

(ii) Select * from student where SNO IN(5, 10)

(A) Only (i) (B) Only (ii)

(C) Both (A) and (B) (D) None

17. UPDATE account SET
DA = basic * .2,
GROSS = basic * 1.3, Where basic > 2000;

(A) The above query displays *DA* and gross for all those employees whose basic is ≥ 2000

(B) The above query displays *DA* and Gross for all employees whose basic is less than 2000

(C) The above query displays updated values of *DA* as well as gross for all those employees whose basic is > 2000

(D) All the above

18. Given two union compatible relations $R_1(A, B)$ and $R_2(C, D)$, what is the result of the operation $R_1\ A = CAB = DR_2$?

(A) $R_1 \cup R_2$ (B) $R_1 \times R_2$

(C) $R_1 - R_2$ (D) $R_1 \cap R_2$

19. Which of the following queries finds the clients of banker Agassi and the city they live in?

(A) $\pi_{client \cdot cname \cdot Ccity}(\sigma_{client.cname}$ = customer c name ($\sigma_{Banker \cdot name = Aggassi}$ (client × customer)

(B) $\pi_{Client.c\ city}$ ($\sigma_{Banker\ name\ =\ 'Aggasi'}$(client × customer)

(C) $\pi_{client \cdot c\ name \cdot Cucity}(\sigma_{client.c\ name\ =\ 'Aggasi'}$ ($\sigma_{client \cdot name\ =\ Cutomer}$ (client × customer)

(D) $\pi_{\cdot c\ name \cdot Cucity}(\sigma_{Bankers}$ name = name ($\sigma_{Banker.\ =\ agassi}$ (client × customer)

20. Consider the following schema pertaining to students data
Student (<u>rno,</u> name, add)
Enroll (rno, <u>Cno,</u> Cname) Where the primary keys are shown Underlined. The no. of tuples in the student and Enroll tables are 120 and 8 respectively. What are the maximum and minimum no. of tuples that can be present in (student * Enroll) where '*' denotes natural join.

(A) 8, 8 (B) 120, 8

(C) 960, 8 (D) 960, 120

Previous Years' Questions

1. Consider the relation account (customer, balance) where customer is a primary key and there are no null values. We would like to rank customers according to decreasing balance. The customer with the largest balance gets rank 1, ties are not broke but ranks are skipped; if exactly two customers have the largest balance they each get rank 1 and rank 2 is not assigned.

Query 1: select A.customer, count (B.customer) from account *A*, account *B* where A.balance <= B.balance group by A.customer
Query 2: select A.customer, 1 + count (B.balance) from account *A*, account *B* where A.balance < B.balance group by A.customer Consider these statements about Query1 and Query2.

1. Query1 will produce the same row set as Query2 for some but not all databases.
2. Both Query1 and Query2 are correct implementation of the specification.
3. Query1 is a correct implementation of the specification but Query2 is not.
4. Neither Query1 nor Query2 is a correct implementation of the specification.
5. Assigning rank with a pure relational query takes less time than scanning in decreasing balance order assigning ranks using ODBC.

Which two of the above statements are correct? **[2006]**

(A) 2 and 5 (B) 1 and 3
(C) 1 and 4 (D) 3 and 5

2. Consider the relation enrolled (student, course) in which (student, course) is the primary key, and the relation paid (student, amount) where student is the primary key. Assume no null values and no foreign keys or integrity constraints. Given the following four queries:

Query1: select student from enrolled where student in (select student from paid)

Query2: select student from paid where student in (select student from enrolled)

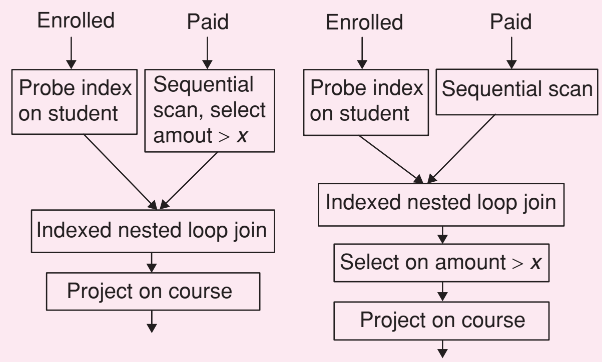
Query3: select E.student from enrolled E, paid P where E.student = P.student

Query4: select student from paid where exists (select * from enrolled where enrolled.student = paid.student)

Which one of the following statement is correct? **[2006]**

(A) All queries return identical row sets for any database
(B) Query2 and Query4 return identical row sets for all databases but there exist databases for which Query1 and Query2 return different row sets
(C) There exist databases for which Query3 returns strictly fewer rows than Query2
(D) There exist databases for which Query4 will encounter an integrity violation at runtime

3. Consider the relation enrolled (student, course), in which (student, course) is the primary key, and the relation paid (student, amount) where student is the primary key. Assume no null values and no foreign keys or integrity constraints. Assume that amounts 6000, 7000, 8000, 9000 and 10000 were each paid by 20% of the students. Consider these query plans (plan 1 on left, plan 2 on right) to 'list all courses taken by students who have paid more than *x*'



A disk seek takes 4 ms, disk data transfer bandwidth is 300 MB/s and checking a tuple to see if amount is greater than x takes 10 μs. Which of the following statements is correct? **[2006]**

(A) Plan 1 and Plan 2 will not output identical row sets for all databases
(B) A course may be listed more than once in the output of Plan 1 for some databases
(C) For $x = 5000$, Plan 1 executes faster than Plan 2 for all databases
(D) For $x = 9000$, Plan 1 executes slower than Plan 2 for all databases

4. Information about a collection of students is given by the relation **studinfo** (studId, name, sex). The relation **enroll** (studId, courseId) gives which student has enrolled for (or taken) what course(s). Assume that every course is taken by at least one male and at least one female student. What does the following relational algebra expression represent?

$$\Pi_{\text{courseId}}((\Pi_{\text{studid}}(\sigma_{\text{sex = 'female'}}(\text{studInfo})) \times \Pi_{\text{courseId}}(\text{enroll})) - \text{enroll}) \quad \textbf{[2007]}$$

(A) Courses in which all the female students are enrolled
(B) Courses in which a proper subset of female students are enrolled.

(C) Courses in which only male students are enrolled.
(D) None of the above

5. Consider the relation **employee** (<u>name</u>, sex, supervisorName) with *name* as the key. *supervisorName* gives the name of the supervisor of the employee under consideration. What does the following Tuple Relational Calculus query produce?

$$e \cdot \text{name} \mid \text{employee}(e) \wedge$$
$$(\forall x)[\neg \text{employee}(x) \vee x \cdot \text{supervisor Name} \neq e \cdot \text{name} \vee$$
$$x \cdot \text{sex} = \text{"male"}]\}$$ **[2007]**

(A) Names of employees with a male supervisor.
(B) Names of employees with no immediate male subordinates.
(C) Names of employees with no immediate female subordinates.
(D) Names of employees with a female supervisor.

6. Consider the table **employee** (<u>empId</u>, name, department, salary) and the two queries Q_1, Q_2 below. Assuming that department 5 has more than one employee, and we want to find the employees who get higher salary than anyone in the department 5, which one of the statements is **TRUE** for any arbitrary employee table?

Q_1: SELECT e.empId
FROM employee e
WHERE not exists
(Select * From employee s where s.department = '5' and s.salary >=e.salary)

Q_2: SELECT e.empId
FROM employee *e*
WHERE e.salary > Any
(Select distinct salary From employee *s* Where s.department = '5') **[2007]**

(A) Q_1 is the correct query
(B) Q_2 is the correct query
(C) Both Q1 and Q2 produce the same answer.
(D) Neither Q_1 nor Q_2 is the correct query

7. Let *R* and *S* be two relations with the following schema
R (<u>*P*</u>, <u>*Q*</u>, *R*1, *R*2, *R*3)
S (<u>*P*</u>, <u>*Q*</u>, *S*1, *S*2)
Where $\{P, Q\}$ is the key for both schemas. Which of the following queries are equivalent?

I. $\Pi_P (R \bowtie S)$
II. $\Pi_P (R) \bowtie \Pi_P (S)$
III. $\Pi_P (\Pi_{P,Q} (R) \cap \Pi_{P,Q} (S))$
IV. $\Pi_P (\Pi_{P,Q} (R) - (\Pi_{P,Q} (R) - (\Pi_{P,Q} (S)))$ **[2008]**

(A) Only I and II (B) Only I and III
(C) Only I, II and III (D) Only I, III and IV

8. Let *R* and *S* be relational schemes such that $R = \{a,b,c\}$ and $S = \{c\}$. Now consider the following queries on the database:

I. $\pi_{R-S}(r) - \pi_{R-S}(\pi_{R-S}(r) \times s - \pi_{R-S,S}(r))$
II. $\{t \mid t \in \pi_{R-S}(r) \wedge \forall u \in s(\exists v \in r(u = v[s] \wedge t = v[R-S]))\}$
III. $\{t \mid t \in \pi_{R-S}(r) \wedge \forall v \in r(\exists u \in s(u = v[s] \wedge t = v[R-S]))\}$
IV. SELECT R.a, R.b
FROM *R*, *S*
WHERE R.c = S.c

Which of the above queries are equivalent? **[2009]**

(A) I and II (B) I and III
(C) II and IV (D) III and IV

Common data for questions 9 and 10: Consider the following relational schema: Suppliers (sid: integer, sname: string, city: string, street: string) Parts(pid: integer, pname: string, color: string) Catalog (sid: integer, pid: integer, cost: real)

9. Consider the following relational query on the above database:

SELECT S.sname
FROM Suppliers S
WHERE S.sid NOT IN (SELECT C.sid
FROM Catalog C
WHERE C.pid NOT IN (SELECT P.pid FROM Parts P
WHERE P.color <> 'blue'))

Assume that relations corresponding to the above schema are not empty. Which one of the following is the correct interpretation of the above query? **[2009]**

(A) Find the names of all suppliers who have supplied a non-blue part.
(B) Find the names of all suppliers who have not supplied a non-blue part.
(C) Find the names of all suppliers who have supplied only blue parts.
(D) Find the names of all suppliers who have not supplied only blue parts.

10. A relational schema for a train reservation database is given below

Passenger (pid, pname, age)
Reservation (pid, cass, tid)

Table :Passenger
Table :Reservation

Pid	pname	Age
0	'Sachin'	65
1	'Rahul'	66
2	'Sourav'	67

Pid	class	tid
0	'AC'	8200
1	'AC'	8201
2	'SC'	8201

3	'Anil'	69

5	'AC'	8203
1	'SC'	8204
3	'AC'	8202

What pids are returned by the following SQL query for the above instance of the tables?

SELECT pid
FROM Reservation
WHERE class = 'AC' AND
EXISTS (SELECT *
  FROM Passenger
  WHERE age > 65 AND
  Passenger.pid = Reservation.pid) **[2010]**

(A) 1, 0 (B) 1, 2
(C) 1, 3 (D) 1, 5

11. Consider a relational table r with sufficient number of records, having attributes $A_1, A_2, \ldots A_n$ and let $1 \le p \le n$. Two queries $Q1$ and $Q2$ are given below.

$Q1$: $\pi_{A_1 \ldots A_n}(\sigma_{A_p=c}(r))$ where c is a constant.

$Q2$: $\pi_{A_1 \ldots A_n}(\sigma_{c_1 \le A_p \le c_2}(r))$ where c_1 and c_2 are constants.

The database can be configured to do ordered indexing on A_P or hashing on A_p. Which of the following statements is TRUE? **[2011]**

(A) Ordered indexing will always outperform hashing for both queries
(B) Hashing will always outperform ordered indexing for both queries.
(C) Hashing will outperform ordered indexing on $Q1$, but not on $Q2$.
(D) Hashing will outperform ordered indexing on $Q2$, but not on $Q1$.

12. Database table by name Loan_Records is given below.

Borrower	Bank manager	Loan amount
Ramesh	Sunderajan	10000.00
Suresh	Ramgopal	5000.00
Mahesh	Sunderajan	7000.00

What is the output of the following SQL query?
SELECT count (*)
FROM (Select Borrower, Bank_Manager FROM Loan Records) AS S
NATURAL JOIN
(SELECT Bank_Manager, Loan_Amount FROM Loan_Records) AS T; **[2011]**

(A) 3 (B) 9
(C) 5 (D) 6

13. Consider a database table T containing two columns X and Y each of type *integer*. After the creation of the table, one record ($X = 1$, $Y = 1$) is inserted in the table.

Let MX and MY denote the respective maximum values of X and Y among all records in the table at any point in time. Using MX and MY, new records are inserted in the table 128 times with X and Y values being $MX + 1$, $2 * MY + 1$ respectively. It may be noted that each time after the insertion, values of MX and MY change. What will be the output of the following SQL query after the steps mentioned above are carried out?

SELECT Y FROM T WHERE $X = 7$; **[2011]**

(A) 127 (B) 255
(C) 129 (D) 257

14. Which of the following statements are true about an SQL query?

P: An SQL query can contain a HAVING clause even if it does not have a GROUP BY clause
Q: An SQL query can contain a HAVING clause only if it has a GROUP BY clause
R: All attributes used in the GROUP BY clause must appear in the SELECT clause
S: Not all attributes used in the GROUP BY clause need to appear in the SELECT clause **[2012]**

(A) P and R (B) P and S
(C) Q and R (D) Q and S

15. Suppose $R_1(\underline{A}, B)$ and $R_2(\underline{C}, D)$ are two relation schemas. Let r_1 and r_2 be the corresponding relation instances. B is a foreign key that refers to C in R_2. If data in r_1 and r_2 satisfy referential integrity constraints, which of the following is always true? **[2012]**

(A) $\Pi_B(r_1) - \Pi_C(r_2) = \varnothing$
(B) $\Pi_C(r_2) - \Pi_B(r_1) = \varnothing$
(C) $\Pi_B(r_1) = \Pi_C(r_2)$
(D) $\Pi_B(r_1) - \Pi_C(r_2) \ne \varnothing$

Common data for questions 16 and 17: Consider the following relations A, B and C:

(A)

Id	Name	Age
12	Arun	60
15	Shreya	24
99	Rohit	11

(B)

Id	Name	Age
15	Shreya	24
25	Hari	40
98	Rohit	20
99	Rohit	11

(C)

Id	Phone	Area
10	2200	02
99	2100	01

16. How many tuples does the result of the following SQL query contain?
SELECT A.Id
FROM A
WHERE A. Age > ALL (SELECT B. Age
FROM B
WHERE B. Name = 'Arun') **[2012]**
(A) 4 (B) 3
(C) 0 (D) 1

17. How many tuples does the result of the following relational algebra expression contain? Assume that the schema of $A \cup B$ is the same as that of A.
$(A \cup B) \bowtie_{A.Id > 40 \vee C.Id < 15} C$ **[2012]**
(A) 7 (B) 4
(C) 5 (D) 9

18. Consider the following relational schema. Students (rollno: integer, sname: string) Courses (courseno: integer, cname: string) Registration(rollno:integer,courseno: integer, percent: real)

Which of the following queries are equivalent to this query in English?

'Find the distinct names of all students who score more than 90% in the course numbered 107'

(I) SELECT DISTINCT S.sname FROM Students as S, Registration as R WHERE R.rollno=S.rollno AND R.courseno=107 AND R.percent>90
(II) $\pi_{sname}(\sigma_{courseno=107 \wedge percent>90}$ Registration $\bowtie$ Students)
(III) $\{T \mid \exists S \in$ Students, $\exists R \in$ Registration (S.rollno=R.rollno $\wedge$ R.courseno=107 $\wedge$ R.percent>90$\wedge$T.sname=S.sname)}
(IV) $\{<S_N> \mid \exists S_R \exists R_P\ (<S_R, S_N> \in$ Students $\wedge <S_R, 107, R_P> \in$ Registration $\wedge R_P > 90)\}$ **[2013]**
(A) I, II, III and IV (B) I, II and III only
(C) I, II and IV only (D) II, III and IV only

19. Given the following statements:
S_1: A foreign key declaration can always be replaced by an equivalent check assertion in SQL.
S_2: Given the table R (a, b, c) where a and b together form the primary key, the following is a valid table definition.
CREATE TABLE S (
a INTEGER
d INTEGER,
e INTEGER,
PRIMARY KEY (d),
FOREIGN KEY (a) references R)
Which one of the following statements is CORRECT? **[2014]**
(A) S_1 is TRUE and S_2 is FALSE
(B) Both $S1$ and S_2 are TRUE
(C) S_1 is FALSE and S_2 is TRUE
(D) Both S_1 and S_2 are FALSE

20. Given the following schema:
Employees (emp–id, first-name, last– name, hire–date, dept–id, salary)
Departments (dept–id, dept–name, manager–id, location–id)
you want to display the last names and hire dates of all latest hires in their respective departments in the location ID 1700. You issue the following query:
SQL > SELECT last–name, hire–date
FROM employees
WHERE (dept–id, hire–date) IN
(SELECT dept–id, MAX (hire–date)
FROM employees JOIN departments USING (dept–id)
WHERE location–id = 1700
GROUP BY dept–id);
What is the outcome? **[2014]**
(A) It executes but does not give the correct result.
(B) It executes and gives the correct result.
(C) It generates an error because of pair wise comparison.
(D) It generates an error because the GROUP BY clause cannot be used with table joins in a subquery.

21. Given an instance of the STUDENTS relation as shown below:

Student ID	Student Name	Student Email	Student Age	CPI
2345	Shankar	shaker @ math	X	9.4
1287	Swati	swati @ ee	19	9.5
7853	Shankar	shankar @ cse	19	9.4
9876	Swati	swati @ mech	18	9.3
8765	Ganesh	ganesh@ civil	19	8.7

For (StudentName, StudentAge) to be a key for this instance, the value X should NOT be equal to _____. **[2014]**

22. Consider a join (relation algebra) between relations ($r(R)$) and ($s(S)$) using the nested loop method. There are three buffers each of size equal to disk block size, out of which one buffer is reserved for intermediate results. Assuming size $r(R) <$ *size* $s(S)$, the join will have fewer number of disk block accesses if **[2014]**
(A) Relation $r(R)$ is in the outer loop
(B) Relation $s(S)$ is in the outer loop
(C) Join selection factor between $r(R)$ and $s(S)$ is more than 0.5
(D) Join selection factor between $r(R)$ and $s(S)$ is less than 0.5

23. SQL allows duplicate tuples in relations, and correspondingly defines the multiplicity of tuples in the result of joins. Which one of the following queries always gives the same answer as the nested query shown below:

Select * from R where a in (select S. a from S) [2014]

(A) Select R.* from R, S where $R.\ a = S.\ a$

(B) Select distinct R * from R, S where $R\ .\ a = S\ .\ a$

(C) Select R.* from R, (select distinct a from S) as $S1$ where $R.a = S1.a$

(D) Select R.* from R, S where $R.a = S.a$ and is unique R

24. What is the optimized version of the relation algebra expression $\pi_{A_1}(\pi_{A_2}(\sigma_{F_1}(\sigma_{F_2(r)})))$, where A_1, A_2 are sets of attributes in r with $A_1 \subset A_2$ and F_1, F_2 are Boolean expressions based on the attributes in r? **[2014]**

(A) $\pi_{A_1}(\sigma_{(F_1 \wedge F_2)(r)})$

(B) $\pi_{A_1}(\sigma_{(F_1 \vee F_2)(r)})$

(C) $\pi_{A_2}(\sigma_{(F_1 \wedge F_2)(r)})$

(D) $\pi_{A_2}(\sigma_{(F_1 \vee F_2)(r)})$

25. Consider the relational schema given below, where **eId** of the relation **dependent** is a foreign key referring to **empId** of the relation **employee**. Assume that every employee has at least one associated dependent in the **dependent** relation.

Consider the following relational algebra query:

employee (<u>empId</u>, empName, empAge)

dependent (<u>depId, eId</u>, depName, depAge)

$\pi_{\text{empId}}(\text{employee})- \pi_{\text{empId}}(\text{employee} \bowtie_{(\text{empId} = \text{eID}) \wedge (\text{empAge} \leq \text{depAge})} \text{dependent})$

The above query evaluates to the set of empIds of employees whose age is greater than that of **[2014]**

(A) some dependent.

(B) all dependents.

(C) some of his/her dependents.

(D) all of his/her dependents.

26. Consider the following relational schema:

employee (<u>empId</u>, empName, empDept)

customer(<u>custId</u>, custName, salesRepid, rating)

salesRepId is a foreign key referring to empId of the employee relation. Assume that each employee makes a sale to at least one customer. What does the following query return?

```
SELECT empName
FROM employee E
WHERE NOT EXISTS
(SELECT custId
FROM customer C
WHERE C.salesRepId = E.empId
AND C.Rating < > 'GOOD');
```
[2014]

(A) Names of all the employees with at least one of their customers having a 'GOOD' rating.

(B) Names of all the employees with at most one of their customers having a 'GOOD' rating.

(C) Names of all the employees with none of their customers having a 'GOOD' rating.

(D) Names of all the employees with all their customers having a 'GOOD' rating.

27. SELECT operation in SQL is equivalent to **[2015]**

(A) The selection operation in relational algebra

(B) The selection operation in relational algebra, except that SELECT in SQL retains duplicates.

(C) The projection operation in relational algebra.

(D) The projection operation in relational algebra, except that SELECT in SQL retains duplicates.

28. Consider the following relations:

Student

Roll No	Student Name
1	Raj
2	Rohit
3	Raj

Performance

Roll No	Course	Marks
1	Math	80
1	English	70
2	Math	75
3	English	80
2	Physics	65
3	Math	80

Consider the following SQL query.

```
SELECT S.Student_Name, sum (P.Marks)
FROM Student S, Performance P
WHERE S.Roll_No = P.Roll_No
GROUP BY S.Student_Name
```

The number of rows that will be returned by the SQL query is ______ **[2015]**

29. Consider two relations $R_1(A, B)$ with the tuples (1, 5), (3, 7) and $R_2(A, C) = (1, 7), (4, 9)$. Assume that $R(A, B, C)$ is the full natural outer join of R_1 and R_2. Consider the following tuples of the form (A, B, C): a = (1, 5, null), b = (1, null, 7), c = (3, null, 9), d = (4, 7, null), e = (1, 5, 7), f = (3, 7, null), g = (4, null, 9). Which one of the following statements is correct? **[2015]**

(A) R contains a, b, e, f, g but not c, d.

(B) R contains all of a, b, c, d, e, f, g.

(C) R contains e, f, g but not a, b.

(D) R contains e but not f, g.

30. Consider the following relation

Cinema (theater, address, capacity)

Which of the following options will be needed at the end of the SQL query

SELECT P_1.address

FROM Cinema P_1

such that it always finds the addresses of theaters with maximum capacity? **[2015]**

(A) WHERE P_1.capacity > = All (select P_2. Capacity from Cinema P_2)

(B) WHERE P_1.capacity >= Any (select P_2. Capacity from Cinema P_2)

(C) WHERE P_1.capacity > All (select max(P_2. capacity) from Cinema P_2)

(D) WHERE P_1.capacity > Any (select max(P_2. capacity) from Cinema P_2)

31. Which of the following is NOT a superkey in a relational schema with attributes *V, W, X, Y, Z* and primary key *VY*? **[2016]**

(A) *V XYZ* (B) *V WXZ*
(C) *V WXY* (D) *V WXYZ*

32. Consider a database that has the relation schema EMP (EmpId, EmpName and DeptName). An instance of the schema EMP and a SQL query on it are given below.

EMP		
EmpId	**EmpName**	**DeptName**
1	XYA	AA
2	XYB	AA
3	XYC	AA
4	XYD	AA
5	XYE	AB
6	XYF	AB
7	XYG	AB
8	XYH	AC
9	XYI	AC
10	XYJ	AC
11	XYK	AD
12	XYL	AD
13	XYM	AE

```
SELECTIVE AVG(EC.Num)
FROM EC
WHERE (DeptName, Num) IN
        (SELECT DeptName, COUNT (EmpId) AS
                                EC(DeptName, Num)
         FROM EMP
         GROUP BY DeptName)
```

The output of executing the SQL query is _______. **[2017]**

33. Consider a database that has the relation schemas EMP(EmpId, EmpName, DeptId), and DEPT(DeptName, DeptId), Note that the DeptId can be permitted to be NULL in the relation EMP. Consider the following queries on the database expressed in tuple relational calculus.

(I) $\{t \mid \exists u \in \text{EMP}(t[\text{EmpName}] = u[\text{EmpName}] \wedge \forall v \in \text{DEPT}(t[\text{DeptId}] \neq v[\text{DeptId}]))\}$

(II) $\{t \mid \exists u \in \text{EMP}(t[\text{EmpName}] = u[\text{EmpName}] \wedge \exists v \in \text{DEPT}(t[\text{DeptId}] \neq v[\text{DeptId}]))\}$

(III) $\{t \mid \exists u \in \text{EMP}(t[\text{EmpName}] = u[\text{EmpName}] \wedge \exists v \in \text{DEPT}(t[\text{DeptId}] = v[\text{DeptId}]))\}$

Which of the above queries are safe? **[2017]**

(A) (I) and (II) only
(B) (I) and (III) only
(C) (II) and (III) only
(D) (I), (II) and (III)

34. Consider a database that has the relation schema CR (studentName, CourseName). An instance of the schema CR is as given below.

CR	
StudentName	**CourseName**
SA	CA
SA	CB
SA	CC
SB	CB
SB	CC
SC	CA
SC	CB
SC	CC
SD	CA
SD	CB
SD	CC
SD	CD
SE	CD
SE	CA
SE	CB
SF	CA
SF	CB
SF	CC

The following query is made on the database.

$T1 \leftarrow \pi_{CouraseName}(\sigma_{StudentName='SA'}(\text{CR}))$

$T2 \leftarrow CR \div T1$

The number of rows in $T2$ is _______. **[2017]**

35. Consider the following database table named *top_scorer*.

top_scorer

player	country	goals
Klose	Germany	16
Ronaldo	Brazil	15
G Miiller	Germany	14
Fontaine	France	13
Pelé	Brazil	12
Klinsmann	Germany	11
Kocsis	Hungary	11
Batistuta	Argentina	10
Cubillas	Peru	10
Lato	Poland	10
Lineker	England	10
T Muller	Germany	10
Rahn	Germany	10

Consider the following SQL query:

```
SELECT ta.player FROM top_scorer AS ta
WHERE ta.goals >ALL (SELECT tb.goals
    FROM top_scorer AS tb
    WHERE tb.country = 'Spain')
AND ta.goals >ANY (SELECT tc.goals
    FROM top_scorer AS tc
    WHERE tc. country = 'Germany')
```

The number of tuples returned by the above SQL query is _________. **[2017]**

36. Consider the following two tables and four queries in SQL.

Book (isbn, bname), Stock (isbn, copies)

Query 1: SELECT B.isbn, S.copies
FROM Book B INNER JOIN Stock S
ON B.isbn = S.isbn;

Query 2: SELECT B.isbn, S.copies
FROM Book B LEFT OUTER
JOIN Stock S
ON B.isbn = S.isbn;

Query 3: SELECT B.isbn, S.copies
FROM Book B RIGHT OUTER
JOIN Stock S
ON B.isbn = S.isbn;

Query 4: SELECT B.isbn, S.copies
FROM Book B FULL OUTER
JOIN Stock S
ON B.isbn = S.isbn;

Which one of the queries above is certain to have an output that is a superset of the outputs of the other three queries? **[2018]**

(A) Query 1 (B) Query 2
(C) Query 3 (D) Query 4

37. Consider the relations $r(A, B)$ and $s(B, C)$, where $s \cdot B$ is a primary key and $r \cdot B$ is a foreign key referencing $s \cdot B$. Consider the query

$$Q: r \bowtie (\sigma_{B<5}(S))$$

Let LOJ denote the natural left outer-join operation. Assume that r and s contain no null values.

Which one of the following queries is NOT equivalent to Q? **[2018]**

(A) $\sigma_{B<5}(r \bowtie s)$ (B) $\sigma_{B<5}(r \text{ LOJ } s)$
(C) $r \text{ LOJ } (\sigma_{B<5}(s))$ (D) $\sigma_{B<5}(r) \text{ LOJ } s$

- First normal form
- Functional dependency
- Inference rules
- Second normal form
- Third normal form
- Higher normal forms (Boyce-Codd normal form)
- Fifth normal form
- Courses

Normalization

Database design theory includes design standards called *normal forms*. The process of making data and tables match these standards is called *normalizing data* or *data normalization*. By normalizing data, we eliminate redundant information and organize table to make it easier to manage the data and make future changes to the table and database structure. This process removes the insertion, deletion, and modification anomalies. In normalizing your data, we usually divide large tables into smaller, easier to maintain tables. We can then use the technique of adding foreign keys to enable connections between the tables.

Data normalization is part of the database design process and is neither specific nor unique to any particular RDBMS. These are in order, such as first, second, third, Boyce-Codd, fourth, and fifth normal forms. Each normal form represents an increasingly stringent set of rules; that is, each normal form assumes that the requirements of the preceding forms have been met. Many relational database designers feel that, if their tables are in third normal form, most common design problems have been addressed. However, the higher-level normal forms can be of use and are included here.

Database normalization is the process of removing redundant data from tables to improve storage efficiency, data integrity and scalability.

1. In the relational model, methods exists for quantifying how efficient a database is, these classifications are called q'.
2. Normalization generally involves splitting existing tables into multiple ones, which must be rejoined (or) linked each time a query is issued.
3. Edgar F. Codd originally established three normal forms: 1NF, 2NF, 3NF. There are others also, but 3NF is widely considered to be sufficient for most applications, most tables when reaching 3NF are also in BCNF (Boyce–Codd normal form).

Table 1

Title	Author 1	Author 2	I SBN	Subject	Pages	Publisher
Database system concepts	Abraham Silber schatz	Henry F. Korth	0072958863	My SQL, computers	1160	McGraw-Hill
OS concepts	Abraham Silberschatz	Henry F. Korth	0471694665	Computers	990	McGraw-Hill

Problems:

1. This table is not very efficient with storage.
2. This design doesn't protect data integrity.
3. This table doesn't scale well.

Anomalies

An anomaly is a variation that differs in some way from what is said to be normal, with respect to maintaining a database.

1. The basic operations performed on Databases are Record insertion, Record updation, Record deletion.

2. It is desirable for these operations to be straight forward and efficient.
3. When relations are not fully normalized they exhibit anomalies.
4. The design goal of database is too easily to understand and to maintain.
5. Anomalies are problems that occur in un-normalized databases where all the data is stored in one table.

Types of anomalies

There are three types of anomalies that can arise in the database because of redundancy as follows:

1. Insertion anomaly
2. Deletion anomaly
3. Updation anomaly

Insertion anomaly An insertion anomaly occurs when particular attributes cannot be inserted into the database without the presence of other attributes.

Example: Consider the following table: Sales

Sales-Rep-Id	Name	Hire-Date	Client
1	Ana	1/1/2015	Madison
2	Sudha	2/4/2014	Peterson
3	Joey	3/2/2014	John
* New			

Insertion anomaly occurs in the above table which stores records for a company's sales representatives and the clients for whom they are responsible.

1. It is not possible to add records for newly hired Sales representatives until they have been assigned to one or more clients.
2. If we insert a record for newly hired, client column will be NULL, which is a required field for the table.
3. It is not possible to record newly hired in the table during training.

Deletion anomaly Deletion anomaly occurs when some particular attributes are lost because of the deletion of other attributes.

Example: Consider the following table 'course'.

S No	C No	S Name	Course
S41	C9201	John	Sales
S42	C9401	Brat	Finance
S40	C9201	Amit	Sales
S43	C9608	Arun	Accounts

Execute the following *SQL* query:

```
Delete     *
From       course
Where      S No = S43
```

If we delete a tuple where SNo = S43, he is the only (or) last student in the accounts department, we will lose data about student 'S43, Arun' as well as data about Accounts course that is 'C9608, Accounts'.

Updation anomaly An updation anomaly occurs when one or more instances of duplicated data are updated but not all.

Example: Consider the 'course' table given in the above example.

If we want to update course – No (Cno) of sales C9201 to C8686, in the course table.

1. It might happen that, the tuple with S No = S41 updated its CNo to C8686, but not the tuple with SNo = S43.
2. Inconsistency occurs in the table, because for the same course sales we have 2 different course Numbers.

Determining keys For a table 'R', its schema R consists of all attributes of R, we say X is a key to R if $X \to R$ means

X determines R
R is dependent upon X
If you know x then you know R

Example: Consider a relation schema R(ABCDE) and the functional dependencies:

$AC \to D$

$B \to E$

$DA \to B$

The closure of AC determines all the attributes present in Relation R, so the key for R is 'AC'.

$AC^+ =$	$\{AC\}$	(self determination)
	$\{ACD\}$	$(AC \to D)$
	$\{ACDB\}$	$(DA \to B)$
	$\{ACDBE\}$	$(B \to E)$

$\therefore$ key = AC

Any attribute which does not appear on the right-hand-side of a given functional dependency appears in any one of the candidate keys.

1. From the above example, neither A (or) C appears in the right hand side of any functional dependency.

First Normal Form (1NF)

In Table 1, we have two violations of 1NF such as:

1. More than one author field and
2. Subject field contains more than one piece of information with more than one value in a single field; thus, it would be very difficult to search for all books on a given subject.

Table 2 *1NF table*

Title	Author	ISBN	Subject	Pages	Publisher
Database system concept	Abrahem Silbers Chatt	0072958863	My SQL	1160	McGraw-Hill
Database system concept	Henry K. Forth	0072958863	Computers	1160	McGraw-Hill
OS concepts	Henry K. Forth	0471694665	Computers	990	McGraw-Hill
OD concepts	Abraham Silber Schatz	0471694665	Computers	990	McGraw-Hill

In Table 2, we have two rows for a single book. Additionally, we would be violating the second NF. A better solution to the problem would be to separate the data into separate tables—an author table and a subject table to store our information, removing that information from the book table.

Table 3 *Subject table*

Subject–ID	Subject
1	My SQL
2	computers

Table 4 *Author table*

Author–ID	Last Name	First name
1	Silberschatz	Abraham
2	Korth	Henry

Table 5 *Book table*

ISBN	Title	Pages	Publisher
00729 58863	Database System Concepts	1160	McGraw-Hill
04716 94665	OS concepts	990	McGraw-Hill

Each table has a primary key, used for joining tables together when querying the data.

A table is in first normal form (1NF) if there are no repeating groups. A repeating group is a set of logically related fields or values that occur multiple times in one record. The sample tables below do not comply with first normal form. Look for fields that contain too much data and repeating group of fields.

EMPLOYEES_PROJECTS_TIME

A table with fields containing too much data.

Employee ID	Name	Project	Time
EN1-26	Sean O'Brien	30-452-T3, 30-457-T3, 32-244-T3	0.25, 0.40, 0.30
EN1-33	Amy Guya	30-452-T3, 30-382-TC, 32-244-T3	0.05, 0.35, 0.60
EN1-35	Steven Baranco	30-452-T3, 31-238-TC	0.15, 0.80
EN1-36	Elizabeth Roslyn	35-152-TC	0.90
EN1-38	Carol Schaaf	36-272-TC	0.75
EN1-40	Alexandra Wing	31-238-TC, 31-241-TC	0.20, 0.70

The example above is also related to another design issue, namely, that each field should hold the smallest meaningful value and that there should not be multiple values in a single field.

Why is this table design a problem?

There would be no way to sort by last names or to know which allocation of time belonged to which project.

EMPLOYEES_PROJECTS_TIME

Table 5 *A table with repeating groups of fields.*

Emp ID	Last Name	First Name	Project1	Time1	Project2	Time2	Project3	Time3
EN1-26	O'Brien	Sean	30-452-T3	0.25	30-457-T3	0.40	32-244-T3	0.30
EN1-33	Guya	Amy	30-452-T3	0.05	30-382-TC	0.35	32-244-T3	0.60
EN1-35	Baranco	Steven	30-452-T3	0.15	31-238-TC	0.80		
EN1-36	Roslyn	Elizabeth	35-152-TC	0.90				
EN1-38	Schaaf	Carol	36-272-TC	0.75				
EN1-40	Wing	Alexandra	31-238-TC	0.20	31-241-TC	0.70		

If an employee was assigned to a fourth project, you would have to add two new fields to the table. Also, it would be very difficult to total the amount of time devoted to a particular project.

The design problems addressed are very common, particularly among new designers who are accustomed to tracking data in a spreadsheet. Often, when building a spreadsheet, we arrange the data horizontally, laying it out across the spreadsheet. When designing tables, we have to think more vertically. Similar data belongs in the same column or field with a single value in each row.

Now we will take the table you saw above and redesign it so it will comply with first normal form.

Look at the repeating groups of data. Identify tables and fields that will hold this data without the repeating groups. Think vertically and remember that similar data belongs in the same field.

Enter the sample data from the table to make sure you don't have repeating groups. If necessary, include foreign key field(s) to connect the tables.

EMPLOYEES

EmployeeID	Last Name	First Name
EN1-26	O'Brien	Sean
EN1-33	Guya	Amy
EN1-35	Baranco	Steven
EN1-36	Roslyn	Elizabeth
EN1-38	Schaaf	Carol
EN1-40	Wing	Alexandra

PROJECTS_EMPLOYEES_TIME

Project Num	EmployeeID	Time
30-328-TC	EN1-33	0.35
30-452-T3	EN1-26	0.25
30-452-T3	EN1-33	0.05
30-452-T3	EN1-35	0.15
31-238-TC	EN1-35	0.80
30-457-T3	EN1-26	0.40
31-238-TC	EN1-40	0.20
31-241-TC	EN1-40	0.70
32-244-T3	EN1-33	0.60
35-152-TC	EN1-36	0.90
36-272-TC	EN1-38	0.75

Mark the primary key field(s) and foreign keys in each table. Shown below with * indicating the Primary key.

EMPLOYEES

EmployeeID	Last Name	First Name
EN1-26	O'Brien	Sean
EN1-33	Guya	Amy
EN1-35	Baranco	Steven
EN1-36	Roslyn	Elizabeth
EN1-38	Schaaf	Carol
EN1-40	Wing	Alexandra

PROJECTS_EMPLOYEES_TIME

Project Num	EmployeeID	Time
30-328-TC	EN1-33	0.35
30-452-T3	EN1-26	0.25
30-452-T3	EN1-33	0.05
30-452-T3	EN1-35	0.15
31-238-TC	EN1-35	0.80
30-457-T3	EN1-26	0.40
31-238-TC	EN1-40	0.20
31-241-TC	EN1-40	0.70
32-244-T3	EN1-33	0.60
35-152-TC	EN1-36	0.90
36-272-TC	EN1-38	0.75

If an employee was assigned to an additional project, it would involve merely adding a new record. Also, it would be much easier to search for a particular project number as they are all held in a single column.

Functional Dependency

A functional dependency is a relationship between fields so that the value in Field *A* determines the value in Field *B*, and there can be only one value in Field *B*. In that case, Field *B* is functionally dependent on Field *A*. Consider the following sample table:

Airport	City
National	Washington, DC
JFK	New York
LaGuardia	New York
Logan	Boston
Dulles	Washington, DC

Each airport name is unique and each airport can be in only one city. Therefore, City is functionally dependent on Airport. The value in the Airport field determines what the value will be in the City field (making Airport the determinant field) and there can be only one value in the City field. This does not need to work in the reverse. As shown in the table, a city can have more than one airport, so Airport is not functionally

dependent on City; the value in City does not necessarily determine what the value in Airport will be.

You will sometimes see a functional dependency written in this format:

Determinant field(s) → Functionally dependent field

as in:

Airport → City

Functional dependency describes the relationship between attributes in a relation.

Example: If A and B are attributes of relation R, and B is functionally dependent on A ($A \rightarrow B$) if each value of A is associated with one value of B.

$$A \xrightarrow[\text{Dependent on A}]{\text{B is functionally}} B$$

Determinant refers to the attributed (or) group attributes on the left-hand side of the arrow of a functional dependency.

Inference Rules

The following inference rules IR 1 through IR 6 form a complete set for inferring functional and multi-valued dependencies from a given set of dependencies

Assume that all attributes are included in a 'universal' relation schema $R = \{A_1, A_2, \ldots A_N)$ and that X, Y, Z and W are subsets of R.

IR 1 (reflexive rule): if $X \supseteq Y$, then $X \rightarrow Y$
IR 2 (Augmentation rule): $\{X \rightarrow Y\} = XZ \rightarrow YZ$
IR 3 (transitive rule): $\{X \rightarrow Y, Y \rightarrow Z\} = X \rightarrow Z$
IR 4 (complementation rule): $\{X \rightarrow \rightarrow Y\} = \{X \rightarrow \rightarrow (R - (X \cup Y))\}$
IR5 (augmentation rule for MVD's): if $X \rightarrow \rightarrow y$ and $W \rightarrow Z$ then $WX \supseteq YZ$
IR6 (transitive rule for MVD's): $\{X \rightarrow \rightarrow Y, Y \rightarrow \rightarrow Z\} = X \rightarrow \rightarrow (Z - Y)$

Second Normal Form

A table is said to be in second normal form if it is in first normal form and each non-key field is functionally dependent on the entire primary key.

Look for values that occur multiple times in a non-key field. This tells us that we have too many fields in a single table.

Example: In the example below, see all the repeating values in the name and Project Title fields. This is an inefficient way to store and maintain data. In a well-designed database, the only data that is duplicated is in key fields used to connect tables. The presumption is that the data in key fields will rarely change, while the data in non-key fields may change frequently.

A table with a multifield primary key and repeating data in non-key fields

EmployeeID	Last Name	First Name	Project Number	Project Title
EN1-26	O'Brien	Sean	30-452-T3	STAR manual
EN1-26	O'Brien	Sean	30-457-T3	ISO procedures
EN1-26	O'Brien	Sean	31-124-T3	Employee handbook
EN1-33	Guya	Amy	30-452-T3	STAR manual
EN1-33	Guya	Amy	30-482-TC	Web Site
EN1-33	Guya	Amy	31-241-TC	New catalogue
EN1-35	Baranco	Steven	30-452-T3	STAR manual
EN1-35	Baranco	Steven	31-238-TC	STAR prototype
EN1-36	Roslyn	Elizabeth	35-152-TC	STAR pricing
EN1-38	Schaaf	Carol	36-272-TC	Order system
EN1-40	Wing	Alexandra	31-238-TC	STAR prototype
EN1-40	Wing	Alexandra	31-241-TC	New catalogue

If a ProjectTitle changed, we would have to edit it in several records. And what would happen in this table if the EmployeeID was part of the primary key and we wanted to add a new ProjectNum and ProjectTitle even though no employees had yet been assigned?

The primary key cannot contain a null value so you couldn't add the new project. Additionally, if a project ended and you wanted to delete it, you would have to delete the individual values because, if we deleted the records containing the titles and an employee was assigned to only that project, you would also delete that employee's record, something that we may not want to do.

In the above example, the asterisks indicate the fields that make up the primary key of this table as it now stands. A multifield primary key is necessary because neither the EmployeeID nor the ProjectNum fields contain unique values.

The reason there are repeated values in LastName, FirstName, and ProjectTitle is that these fields are dependent

on only part of the primary key. The value in EmployeeID determines what the value in LastName will be, but the value in ProjectNum has nothing to do with it. Similarly, the value in ProjectNum determines the value in ProjectTitle, but EmployeeID does not. These non-key fields relate to only part of the primary key. They are not functionally dependent on the entire primary key.

The solution to this lies in breaking the table into smaller tables that do meet second normal form. You will find that more tables are the solution to most problems encountered during data normalisation.

EMPLOYEES

EmployeeID	Last Name	First Name
EN1-26	O'Brien	Sean
EN1-33	Guya	Amy
EN1-35	Baranco	Steven
EN1-36	Roslyn	Elizabeth
EN1-38	Schaaf	Carol
EN1-40	Wing	Alexandra

EMPLOYEES_PROJECTS

EmployeeID	Project Num
EN1-26	30-452-T3
EN1-26	30-457-T3
EN1-26	31-124-T3
EN1-33	30-328-TC
EN1-33	30-452-T3
EN1-33	32-244-T3
EN1-35	30-452-T3
EN1-35	31-238-TC
EN1-36	35-152-TC
EN1-38	36-272-TC
EN1-40	31-238-TC
EN1-40	31-241-TC

Now we'll take the table above and design new tables that will eliminate the repeated data in the non-key fields.

1. To decide what fields belong together in a table, think about which field determines the values in other fields. Create a table for those fields and enter the sample data.
2. Think about what the primary key for each table would be and about the relationship between the tables. If necessary, add foreign keys or a junction table.
3. Mark the primary key for each table and make sure that you don't have repeating data in non-key fields.

PROJECTS

Projec tNum	Project Title
30-452-T3	STAR manual
30-457-T3	ISO procedures
30-482-TC	Web site
31-124-T3	Employee handbook
31-238-TC	STAR prototype
31-238-TC	New catalog
35-152-TC	STAR pricing
36-272-TC	Order system

Examine the tables to make sure there are no repeating values in non-key fields and that the value in each non-key field is determined by the value(s) in the key field(s). This removes the modification anomaly of having the repeated values.

Third Normal Form

A table is said to be in third normal form if it is in second normal form (2NF) and there are no transitive dependencies.

A transitive dependency is a type of functional dependency in which the value in a non-key field is determined by the value in another non-key field and that field is not a candidate key. Again, look for repeated values in a non-key field as in the following example.

A table with a single field primary key and repeating values in non-key fields.

Project Num	Project Title	Project Mgr	Phone
30-452-T3	STAR manual	Garrison	2756
30-457-T3	ISO procedures	Jacanda	2954
30-482-TC	Web site	Friedman	2846
31-124-T3	Employee handbook	Jones	3102
31-238-TC	STAR prototype	Garrison	2756
31-241-TC	New catalog	Jones	3102
35-152-TC	STAR pricing	Vance	3022
36-272-TC	Order system	Jacanda	2954

The phone number is repeated each time a manager's name is repeated. It is dependent on the manager, which is dependent on the project number (a transitive dependency).

The Project Manager field is not a candidate key, because the same person manages more than one project. Again, the solution is to remove the field with repeating data to a separate table.

Take the above table and create new tables to fix the problem.

1. Think about which fields belong together and create new tables to hold them.
2. Enter the sample data and check for unnecessarily (not part of primary key) repeated values.
3. Identify the primary key for each table and, if necessary, add foreign keys.

PROJECTS

Project Num	Project Title	Project Mgr
30-452-T3	STAR manual	Garrison
30-457-T3	ISO procedures	Jacanda
30-482-TC	Web site	Friedman
31-124-T3	Employee handbook	Jones
31-238-TC	STAR prototype	Garrison
31-241-TC	New catalog	Jones
35-152-TC	STAR pricing	Vance
36-272-TC	Order system	Jacanda

MANAGERS

Project Manager	Phone
Friedman	2846
Garrison	2756
Jacanda	2954
Jones	3102
Vance	3022

Reexamine your tables to make sure there are no unnecessarily repeating values in non-key fields and that the value in each non-key field is determined by the value(s) in the key field(s). In most cases, 3NF should be sufficient to ensure that your database is properly normalised.

Higher Normal Forms (Boyce–Codd Normal Form)

A table is in third normal form (3NF), and all determinants are candidate keys.

Boyce–Codd normal form (BCNF) can be thought of as a 'new' third normal form. It was introduced to cover situations that the 'old' third normal form did not address. The mean of a determinant (determines the value in another field) and candidate keys (qualify for designation as primary key). This normal form applies to situations where you have overlapping candidate keys.

If a table has no non-key fields, it is automatically in BCNF (Figure 1). Look for potential problems in updating existing data (modification anomaly) and in entering new data (insertion anomaly).

Imagine that we were designing a table for a college to hold information about courses, students, and teaching assistants. We have the following business rules:

1. Each course can have many students.
2. Each student can take many courses.
3. Each course can have multiple teaching assistants (TAs).
4. Each TA is associated with only one course.
5. For each course, each student has one TA.

Some sample data:

COURSES_STUDENTS_TA's

CourseNum	Student	TA
ENG101	Jones	Clark
ENG101	Grayson	Chen
ENG101	Samara	Chen
MAT350	Grayson	Powers
MAT350	Jones	O'Shea
MAT350	Berg	Powers

To uniquely identify each record, we could choose CourseNum + Student as a primary key. This would satisfy third normal form also because the combination of CourseNum and Student determines the value in TA. Another candidate key would be Student + TA. In this case, you have overlapping candidate keys (Student is in both). The second choice, however, would not comply with third normal form, because the CourseNum is not determined by the combination of Student and TA; it only depends on the value in TA. This is the situation that Boyce-Codd normal form addresses; the combination of Student + TA could not be considered to be a candidate key.

If we wanted to assign a TA to a course before any students enrolled, we couldn't because Student is part of the primary key. Also, if the name of a TA changed, would have to update it in multiple records. If assume have just these fields, this data would be better stored in three tables: one with CourseNum and Student, another with Student and TA, and third with CourseNum and TA.

COURSES

Course Num	Student
ENG101	Jones
ENG101	Grayson
ENG101	Samara
MAT350	Grayson
MAT350	Jones
MAT350	Berg

STUDENTS

Student	TA
Jones	Clark
Grayson	Chen
Samara	Chen
Grayson	Powers
Jones	O'Shea
Berg	Powers

TA's

*CourseNum	*TA
ENG101	Clark
ENG101	Chen
MAT350	O'Shea
MAT350	Powers

Figure 1 Tables that comply with BCNF.

Fourth Normal Form

A table is in Boyce-Codd normal form (BCNF) and there are no multi-valued dependencies.

A *multi-valued dependency* occurs when, for each value in field *A*, there is a set of values for field *B* and a set of values for field *C* but fields *B* and *C* are not related.

Look for repeated or null values in non-key fields. A multi-valued dependency occurs when the table contains fields that are not logically related. An often used example is the following table:

MOVIES

Movie	Star	Producer
Once Upon a Time	Julie Garland	Alfred Brown
Once Upon a Time	Mickey Rooney	Alfred Brown
Once Upon a Time	Julie Garland	Muriel Humphreys
Once Upon a Time	Mickey Rooney	Muriel Humphreys
Moonlight	Humphrey Bogart	Alfred Brown
Moonlight	Julie Garland	Alfred Brown

A movie can have more than one star and more than one producer. A star can be in more than one movie. A producer can produce more than one movie. The primary key would have to include all three fields, and so this table would be in BCNF. But you have unnecessarily repeated values, with the data maintenance problems that causes and you would have trouble with deletion anomalies.

The Star and the Producer really aren't logically related. The Movie determines the Star and the Movie determines the Producer. The answer is to have a separate table for each of those logical relationships: one holding Movie and Star and the other with Movie and Producer, as shown below:

STARS

*Movie	*Star
Once Upon a Time	Julie Garland
Once Upon a Time	Mickey Rooney
Moonlight	Humphrey Bogart
Moonlight	Julie Garland

PRODUCERS

*Movie	*Producer
Once Upon a Time	Alfred Brown
Once Upon a Time	Muriel Humphreys
Moonlight	Alfred Brown

Above, showing tables that comply with 4NF

Below is another example of a common design error, and it's easily spotted by all the missing or blank values.

PROJECTS_EQUIPMENT

Dept Code	Project Num	Project Mgr ID	Equipment	Property ID
IS	36-272-TC	EN1-15	CD-ROM	657
IS			VGA desktop monitor	305
AC	35-152-TC	EN1-15		
AC			Dot-matrix printer	358
AC			Calculator with tape	239
TW	30-452-T3	EN1-10	486 PC	275
TW	30-457-T3	EN1-15		
TW	31-124-T3	EN1-15	Laser printer	109
TW	31-238-TC	EN1-15	Handheld scanner	479
RI			Fax machine	775
MK			Laser printer	858
MK			Answering machine	187
TW	31-241-TC	EN1-15	Standard 19200 bps modem	386
SL			486 Laptop PC	772
SL			Electronic notebook	458

A table with many null values (Note: It also does not comply with 3NF and BCNF).

It is the same problem here because not all of the data is logically related. As usual, the answer is more tables: one to hold the information on the equipment assigned to departments (with PropertyID as the primary key) and another with projects and departments. We would now the business rules to know whether a project might involve more than one department or manager and be able to figure out the primary key. Assuming a project can have only one manager and be associated with only one department, the tables would be as follows:

EQUIPMENT

*Property ID	Equipment	DeptCode
657	CD-ROM	IS

Figure 2 Tables that eliminate the null values and comply with 4NF.

Fifth Normal Form

A table is in fourth normal form (4 NF) and there are no cyclic dependencies.

A *cyclic dependency* can occur only when you have a multifield primary key consisting of three or more fields. For example, let's say your primary key consists of fields *A*, *B*, and *C*. A cyclic dependency would arise if the values in those fields were related in pairs of *A* and *B*, *B* and *C*, and *A* and *C*.

Fifth normal form is also called *projection-join normal form*. A *projection* is a new table holding a subset of fields from an original table. When properly formed projections are joined, they must result in the same set of data that was contained in the original table.

Look for the number of records that will have to be added or maintained

Following is some sample data about buyers, the products they buy, and the companies they buy from.

BUYING

Buyer	Product	Company
Chris	Jeans	Levi
Chris	Jeans	Wrangler
Chris	Shirts	Levi
Lori	Jeans	Levi

Figure 3 A table with cyclic dependencies.

The primary key consists of all three fields. One data maintenance problem that occurs is that you need to add a record for every buyer who buys a product for every company that makes that product or they can't buy from them. That may not appear to be a big deal in this sample of two buyers, two products, and two companies ($2 \times 2 \times 2 = 8$ total records). But what if we went to 20 buyers, 50 products, and 100 companies ($20 \times 50 \times 100 = 100{,}000$ potential records)? It quickly gets out of hand and becomes impossible to maintain.

We might solve this by dividing this into the following two tables:

BUYERS

Buyer	Product
Chris	jeans
Chris	shirts
Lori	jeans

PRODUCTS

Product	Company
jeans	Wrangler
jeans	Levi
shirts	Levi

However, if you joined the two tables above on the Product field, it would produce a record not part of the original data set (it would say that Lori buys jeans from Wrangler). This is where the projection-join concept comes in.

The correct solution would be three tables:

BUYERS

*Buyer	*Product
Chris	jeans
Chris	shirts
Lori	jeans

PRODUCTS

*Product	*Company
jeans	Wrangler
jeans	Levi
shirts	Levi

COMPANIES

*Buyer	*Company
Chris	Levi
Chris	Wrangler
Lori	Levi

Figure 4 Tables that comply with 5NF.

When the first two tables are joined by Product and the result joined to the third table by Buyer and Company, the result is the original set of data.

Exercises

Practice Problems I

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider the given functional dependencies

$A \to B$

$BC \to DE$

$AEF \to G$

Which of the following is true?

(A) Functional dependency $ACF \to DG$ implied by the set
(B) Functional dependency $ACF \to DG$ cannot be implied by the set
(C) Functional dependency $AB \to G$ implied by the set
(D) Both (B) and (C)

2. Consider the given relation

DNAME	DNO	MGRNO	LOCATION
RESEARCH	5	333	{BANGLORE,DELHI, HYDERABAD}
ADMINISTRATION	4	987	{CHENNAI}
EXECUTIVES	1	885	{HYDERABAD}

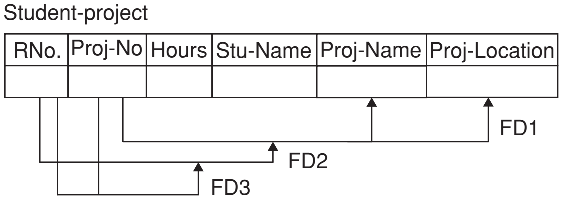
Department

The given relation is

(A) is not in 1NF (B) in 1NF
(C) in 2NF (D) in 3NF

3. Consider the given Relational scheme

Student-project

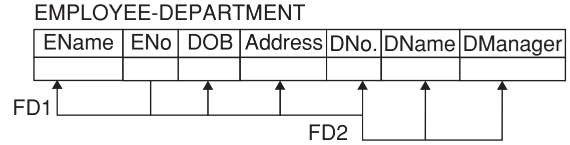


Which functional dependencies are violating 2NF property?

(A) FD1 (B) FD2
(C) FD3 (D) Both A and B

4. Consider the given relation

EMPLOYEE-DEPARTMENT



Which functional dependencies are violating 3NF?

(A) FD1 (B) FD2
(C) Both (D) None of these

5. Consider the given relation $R(A, B, C, D)$and functional dependencies:

$FD = (AB \to C$

$C \to B$

$C \to D)$

Determine the key, prime attributes and non-prime attributes.

(A) $\{A\}, \{AB\}, \{CDE\}$
(B) $\{AB, AC\}, \{ABC\}, \{D\}$
(C) $\{AB, BC\}, \{ABC\}, \{D\}$
(D) $\{AB, AC\}, \{AB\}, \{D\}$

6. Consider the given relation and functional dependencies

$R(ABCDE)$

$FD = (ABD \to C$

$BC \to D$

$CD \to E)$

Determine the key, prime attributes, non-prime attributes and the normal form of the relation?

(A) $\{AB, AD\}, \{ABCD\}, \{E\}$
(B) $\{ABC, ABD\}, \{ABCD\}, \{E\}$
(C) $\{AB, AD\}, \{ABC\}, \{DE\}$
(D) $\{ABC, ABD\}, \{AB\}, \{CDE\}$

7. Consider the given relation and functional dependencies
$R(ABC)$
$FD = (AB \to C$
$C \to A)$
The relation is in which normal form?
(A) 1NF (B) 2NF
(C) 3NF (D) BCNF

8. Consider the given relation and its functional dependencies:
$R(ABCDE)$
$FD = (AB \to C$
$C \to E$
$B \to D$
$E \to A)$
The relation is further decomposed into two relations:
$R_1(BCD), R_2(ACE)$
(A) Decomposition is lossy and dependency preserving
(B) Decomposition is lossless and dependency preserving
(C) Decomposition is lossy and not dependency preserving
(D) Decomposition is lossless and not dependency preserving

9. Consider the following relational instance:

X	Y	Z
1	4	2
1	5	3
1	6	3
3	2	2

Which of the following functional dependencies are satisfied by the instance?
(A) $xy \to z$ and $z \to y$
(B) $yz \to x$ and $y \to z$
(C) $yz \to x$ and $x \to z$
(D) $xz \to y$ and $y \to x$

10. Consider the following functional dependencies:
DOB $\to$ Age
Age $\to$ Eligibility
Name $\to$ RNo
RNo $\to$ Name
CourseNo $\to$ CourseName
CourseNo $\to$ Instructor
(RNo, CNo) $\to$ Grade
The relation (RNo, Name, DOB, Age) is in which normal form?
(A) 1NF (B) 2NF
(C) 3NF (D) BCNF

11. Consider the given functional dependencies:
$AB \to CD$
$AF \to D$
$DE \to F$
$C \to G$
$F \to E$
$G \to A$
Which of the following is false?
(A) $\{CF\}^+ = \{ACDEFG\}$
(B) $\{BG\}^+ = \{ABCDG\}$
(C) $\{AF\}^+ = \{ACDEFG\}$
(D) $\{AB\}^+ = \{ABCDG\}$

12. What should be the key to make the given relation to be in BCNF? The dependencies for the following, 'Grades' relation are GRADES (student-Id, course#, semester#, Grade) student-Id, course#, semester# $\to$ Grade
(A) student-Id
(B) course#
(C) semester#
(D) student-Id, course#, semester #

13. What normal from is the following relation in?
STORE_ITEM (SKU, promotionID, vendor, style, price)
SKU, promotionID $\to$ vendor, style, price
SKU $\to$ vendor, style
(A) 1NF (B) 2NF
(C) 3NF (D) 4NF

14. What normal form is the following relation in?
Only H, I can act as the key
STUFF (H, I, J, K, L, M, N, O)
$H, I \to$ J,K,L
$J \to M$
$K \to N$
$L \to O$?
(A) 1NF (B) 2NF
(C) 3NF (D) BCNF

15. What normal form the following relation is in?
STUFF2(D, O, N, T, C, R, Y)
$D, O \to N, T, C, R, Y$
$C, R \to D$
$D \to N$?
(A) 1NF (B) 2NF
(C) 3NF (D) BCNF

16. The given table is in the BCNF form, convert it to the 4th normal form.

Employee	Skill	Language
Jones	Electrical	French
Jones	Electrical	German
Jones	Mechanical	French
Jones	Mechanical	German
Smith	Plumbing	Spanish

(A)

Employee	Skill

(B)

Employee	Language

(C)

Skill	Language

(D) Both A and B

17. For a database relation $x(a, b, c, d)$, where all the domains of a, b, c, d, include only atomic values, only the following FDs and those that can be inferred from them hold.
$a \to b, c \to d$
the relation is
(A) In 1st NF but not in 2nd NF
(B) In 2nd NF but not in 3rd NF
(C) In 2nd NF
(D) In 3rd NF

18. Which of the following FDs are satisfied by the instance from the below relation:

A	B	C
2	8	4
2	10	6
2	12	6
6	4	4

(A) AB → C and C → B
(B) BC → A and B → C
(C) BC → A and A → C
(D) AC → B and B → A

19. Consider the following database:
Course # → Title
Course # time → location
Emp – ID → T –Name salary
is in
(A) 3NF (B) 2NF
(C) 1NF (D) BCNF

20. Consider the following schema
$A = (w, x, y, z)$ and the dependencies are
$W \to X, X \to Y, Y \to Z$, and $Z \to W$
Let $A = (A_1$ and $A_2)$ be a decomposition such that $A_1 \cap A_2 = \phi$
The decomposition is
(A) In 1NF and in 2NF
(B) In 2NF and not in 3NF
(C) In 2NF and in 3NF
(D) Not in 2NF and in 3NF

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Integrity constraints ensures that changes made to the database by authorized users do not result in
(A) Loss of FDs
(B) Loss of keys
(C) Loss of tables
(D) Loss of data consistency

2. Relation $R = (\overline{A}, B, C, D)$ with AB as primary key. Choose one FD such that R should be in 1NF but not in 2NF
(A) $AB \to C$
(B) $AB \to D$
(C) $A \to D$
(D) $AB \to CD$

3. A normalized relation (1NF) can be retrieved from unnormalized relation by removing
(A) repeating groups (B) duplicate tuples
(C) transitive dependency (D) primary key

4. A relation will be in 2NF, if we
(A) remove repeating groups
(B) remove partial dependency
(C) remove transitive dependency
(D) have overlapping candidate key

5. Relation $R = (A, B, C, D)$ with AB as primary key, choose the FD so that R should be in 2NF but not in 3NF.
(A) $D \to C$ (B) $AB \to C$
(C) $AB \to D$ (D) $A \to B$

6. If a relation is in 2NF, then it can be in 3NF by removing
(A) repeating groups
(B) partial dependencies
(C) transitive dependencies
(D) overlapping dependencies

7. BCNF can be achieved from 3NF by removing
(A) repeating groups
(B) partial dependencies
(C) transitive dependencies
(D) overlapping dependencies

8. Which one of the following is not possible?
(A) Relation is in BCNF but not in 4NF
(B) Relation is in 3NF but not in BCNF
(C) Relation is in 2NF but not in 3NF
(D) Relation is in 3NF but not in 2NF

Common data for questions 9 and 10: Let R be a relation schema R (A, B, C, D);

$F = \{AB \rightarrow CD;\ C \rightarrow A\}$ F is the set of functional dependencies

9. How many prime attributes are there?
(A) 1 (B) 2
(C) 3 (D) 4

10. The highest normal form of the above relation is
(A) 1NF (B) 2NF
(C) 3NF (D) 4NF

Linked answer questions

11. For a given relation schema $R = \{A, B, C, D, E\}$
$A \rightarrow BC$
$CD \rightarrow E$
$B \rightarrow D$
$E \rightarrow A$
Which of the following is not a candidate key?
(A) A (B) B
(C) E (D) BC

12. For the above answer, what is the closure?
(A) BD (B) ABC
(C) $ABCDE$ (D) BC

13. Consider the following functional dependencies:
$A \rightarrow B$
$C \rightarrow D$
$B \rightarrow E$
$F \rightarrow A$
The relation (A, B, C, D) is
(A) in second normal form, but not in third normal form
(B) in third normal form, but not in $B\ C\ N\ F$
(C) in $B\ C\ N\ F$
(D) None of the above

Common data for questions 14 and 15:
$R = (A, B, C, D, E, F)$
FDs = $A \rightarrow B$
$C \rightarrow$ DF
$AC \rightarrow E$
$D \rightarrow F$

14. Determine the key from the given FDs:
(A) AB (B) AC
(C) ACB (D) ACD

15. Decompose the FDs into 2NF
(A) $R_1(AB)\ R_2(CDF)\ R_3(ACE)$
(B) $R_1(AB)\ R_2(CDEF)$
(C) $R_1(ABC)\ R_2(CDF)$
(D) $R_1(AB)\ R_2(CD)\ R_3(EF)$

16. For a database relation $x(a, b, c, d)$, where all the domains of a, b, c, d, include only atomic values, only the following FDs and those that can be inferred from them hold.
$a \rightarrow b,\ c \rightarrow d$
The relation is decomposed into $R_1(ab)$, $R_2(cd)$. Which of the following is true, The decomposition
(A) is dependency preserving
(B) is not dependency preserving
(C) is loss less
(D) Both A and C

17. Which of the following FDs are satisfied by the instance from the below relation?

A	B	C
4	12	8
4	14	10
4	16	10
10	8	8

(A) $AB \rightarrow C$ and $C \rightarrow B$
(B) $BC \rightarrow A$ and $B \rightarrow C$
(C) $BC \rightarrow A$ and $A \rightarrow C$
(D) $AC \rightarrow B$ and $B \rightarrow A$

18. Indicate which of the following statements are false: 'A relational database, which is in 3NF still have undesirable data redundancy because there may exist.
(A) Below all
(B) Non trivial FDs involving prime attributes on the right side.
(C) Non-trivial FDs involving prime attributes on the left side
(D) Non-trivial FDs involving only prime attributes

19. Consider the following database:
SOFTWARE (software-vendor, product, Release-date, systemReq, warranty)
FD: (software-vendor, product, Releasedate) $\rightarrow$ system Req, price, Warranty.
Which of the following are non–prime attributes?
(A) SystemReq
(B) Price
(C) Warranty
(D) All the above

20. Consider a relation schema R (A, B, C, D, E, X, Y) with the following FDs
$F = \{0 \rightarrow A, XD \rightarrow C, DA \rightarrow B, A \rightarrow X, XE \rightarrow B, E \rightarrow A, B \rightarrow D, DA \rightarrow B, EB \rightarrow C, AB \rightarrow C, Y \rightarrow B, C \rightarrow B\}$
is in
(A) 2NF
(B) 3NF
(C) 4NF
(D) BCNF

Previous Years' Questions

1. Which one of the following statements is false? **[2007]**
(A) Any relation with two attributes is in BCNF
(B) A relation in which every key has only one attribute is in 2NF
(C) A prime attribute can be transitively dependent on a key in a 3NF relation.
(D) A prime attribute can be transitively dependent on a key in a BCNF relation.

2. Consider the following relational schemas for a library database:

Book (Title, Author, Catalog_ no, Publisher, Year, Price)

Collection (Title, Author, Catalog_ no)

with the following functional dependencies:

I. Title Author $\rightarrow$ Catalog_no

II. Catalog_no $\rightarrow$ Title Author Publisher Year

III. Publisher Title Year $\rightarrow$ Price

Assume {Author, Title} is the key for both schemas. Which of the following statements is true? **[2008]**
(A) Both Book and Collection are in BCNF
(B) Both Book and Collection are in 3NF only
(C) Book is in 2NF and Collection is in 3NF
(D) Both Book and Collection are in 2NF only

3. The following functional dependencies hold for relations $R(A, B, C)$ and $S(B, D, E)$
$B \rightarrow A,$
$A \rightarrow C$

The relation R contains 200 tuples and the relation S contains 100 tuples. What is the maximum number of tuples possible in the natural join $R \bowtie S$? **[2010]**
(A) 100 (B) 200
(C) 300 (D) 2000

4. Which of the following is true? **[2012]**
(A) Every relation in 3NF is also in BCNF
(B) A relation R is in 3NF if every non-prime attribute of R is fully functionally dependent on every key of R
(C) Every relation in BCNF is also in 3NF
(D) No relation can be in both BCNF and 3NF

Common data questions 5 and 6: Relation R has eight attributes ABCDEFGH, Fields of R contain only atomic values.

$F = \{CH \rightarrow G, A \rightarrow BC, B \rightarrow CFH, E \rightarrow A, F \rightarrow EG\}$ is a set of functional dependencies (FDs) so that F^+ is exactly the set of FDs that hold for R.

5. How many candidate keys does the relation R have? **[2013]**
(A) 3 (B) 4
(C) 5 (D) 6

6. The relation R is **[2013]**
(A) in 1NF, but not in 2NF
(B) in 2NF, but not in 3NF
(C) in 3NF, but not in BCNF
(D) in BCNF

7. Assume that in the suppliers relation above, each supplier and each street within a city has a unique name, and (sname, city) forms a candidate key. No other functional dependencies are implied other than those implied by primary and candidate keys. Which one of the following is true about the above schema? **[2009]**
(A) The schema is in BCNF
(B) The schema is in 3NF but not in BCNF
(C) The schema is in 2NF but not in 3NF
(D) The schema is not in 2NF

8. Consider the relation scheme $R = (E, F, G, H, I, J, K, L, M, N)$ and the set of functional dependencies $\{\{E, F\} \rightarrow \{G\}, \{F\} \rightarrow \{I, J\}, \{E, H\} \rightarrow \{K, L\}, \{K\} \rightarrow \{M\}, \{L\} \rightarrow \{N\}\}$ on R. What is the key for R? **[2014]**
(A) $\{E, F\}$ (B) $\{E, F, H\}$
(C) $\{E, F, H, K, L\}$ (D) $\{E\}$

9. Given the following two statements:

S_1: Every table with two single-valued attributes is in 1NF, 2NF, 3NF and BCNF

S_2: $AB \rightarrow C, D \rightarrow E, E \rightarrow C$ is a minimal cover for the set of functional dependencies $AB \rightarrow C, D \rightarrow E, AB \rightarrow E, E \rightarrow C$

Which one of the following is correct? **[2014]**
(A) S_1 is true and S_2 is false
(B) Both S_1 and S_2 are true
(C) S_1 is false and S_2 is true
(D) Both S_1 and S_2 are false

10. The maximum number of super-keys for the relation schema R (E, F, G, H) with E as the key is ______. **[2014]**

11. A *prime attribute* of a relation scheme R is an attribute that appears **[2014]**
(A) in all candidate keys of R
(B) in some candidate key of R
(C) in a foreign key of R
(D) only in the primary key of R

12. Consider an entity-Relationship (ER) model in which entity sets E_1 and E_2 are connected by an m:n relationship R_{12}. E_1 and E_3 are connected by a 1:n (1 on the side of E_1 and n on the side of E_3) relationship R_{13}.

E_1 has two single-valued attributes a_{11} and a_{12} of which a_{11} is the key attribute. E_2 has two single-valued

attributes a_{21} and a_{22} of which a_{21} is the key attribute. E_3 has two single-valued attributes a_{31} and a_{32} of which a_{31} is the key attribute. The relationships do not have any attributes.

If a relational model is derived from the above ER model, then the minimum number of relations that would be generated if all the relations are in 3 NF is _______. **[2015]**

13. Consider the relation $X(P, Q, R, S, T, U)$ with the following set of functional dependencies

```
F = {
    {P, R} → {S, T}
    {P, S, U} → {Q, R}
    }
```

Which of the following is the trivial functional dependency in $F+$, where $F+$ is closure of F? **[2015]**

(A) $\{P, R\} \rightarrow \{S, T\}$
(B) $\{P, R\} \rightarrow \{R, T\}$
(C) $\{P, S\} \rightarrow \{S\}$
(D) $\{P, S, U\} \rightarrow \{Q\}$

14. A database of research articles in a journal uses the following schema. **[2016]**

(VOLUME, NUMBER, STARTPAGE, ENDPAGE, TITLE, YEAR, PRICE)

The primary key is (VOLUME, NUMBER, STARTPAGE,ENDPAGE) and the following functional dependencies exist in the schema.

(VOLUME, NUMBER, STARTPAGE, ENDPAGE) → TITLE

(VOLUME, NUMBER) → YEAR

(VOLUME, NUMBER,
STARTPAGE,ENDPAGE) → PRICE

The database is redesigned to use the following schemas.

(VOLUME, NUMBER, STARTPAGE, ENDPAGE, TITLE, PRICE)

(VOLUME, NUMBER, YEAR)

Which is the weakest normal form that the new database satisfies, but the old one does not?

(A) 1NF (B) 2NF
(C) 3NF (D) BCNF

15. Consider the following database table water_schemes: **[2016]**

water_schemes		
scheme_no	**District name**	**Capacity**
1	Ajmer	20
1	Bikaner	10
2	Bikaner	10
3	Bikaner	20
1	Churu	20
2	Churu	20
1	Dungargarh	10

The number of tuples returned by the following SQL query is ______ .

with total (name, capacity) **as**
select district _ name, **sum** (capacity)
from water _ schemes
group by district _ name
with total _avg (capacity) **as**
select avg (capacity)
from total
select name
from total, total _ avg
where total . capacity ≥ total_avg. capacity

16. The following functional dependencies hold true for the relational schema $R\ \{V, W, X, Y, Z\}$:

$$V \rightarrow W$$
$$VW \rightarrow X$$
$$Y \rightarrow VX$$
$$Y \rightarrow Z$$

Which of the following is irreducible equivalent for this set of set of functional dependencies? **[2017]**

(A) $V \rightarrow W$, $V \rightarrow X$, $Y \rightarrow V$, $Y \rightarrow Z$
(B) $V \rightarrow W$, $W \rightarrow X$, $Y \rightarrow V$, $Y \rightarrow Z$
(C) $V \rightarrow W$, $V \rightarrow X$, $Y \rightarrow V$, $Y \rightarrow X$, $Y \rightarrow Z$
(D) $V \rightarrow W$, $W \rightarrow X$, $Y \rightarrow V$, $Y \rightarrow X$, $Y \rightarrow Z$

17. Consider the following tables T1 and T2.

T1

P	Q
2	2
3	8
7	3
5	8
6	9
8	5
9	8

T2

R	S
2	2
8	3
3	2
9	7
5	7
7	2

In table T1, **P** is the primary key and **Q** is the foreign key referencing **R** in table T2 with on-delete cascade and on-update cascade. In table T2, **R** is the primary key and **S** is the foreign key referencing **P** in table Tl

with on-delete set NULL and on-update cascade. In order to delete record ⟨3, 8⟩ from table T1, the number of additional records that need to be deleted from table T1 is __________. **[2017]**

18. Consider the following four relational schemas. For each schema, all non-trivial functional dependencies are listed. The underlined attributes are the respective primary keys.

Schema I:

Registration (<u>rollno,</u> courses)

Field 'courses' is a set-valued attribute containing the set of courses a student has registered for.

Non-trivial functional dependency:

Rollno → courses

Schema II:

Registration (<u>rollno, courseid</u>, email)

Non-trivial functional dependencies:

Rollno, courseid → email

email → rollno

Schema III:

Registration (<u>rollno, courseid</u>, marks, grade)

Non-trivial functional dependencies:

Rollno, courseid → marks, grade

Marks → grade

Schema IV:

Registration (<u>rollno, courseid,</u> credit)

Non-trivial functional dependencies:

Rollno, courseid → credit

Courseid → credit

Which one of the relational schemas above is in 3NF but not in BCNF? **[2018]**

(A) Schema I
(B) Schema II
(C) Schema III
(D) Schema IV

Chapter 4

Transaction and Concurrency

LEARNING OBJECTIVES

- *Transactions and concurrency control*
- *Transaction*
- *Transaction properties*
- *Uncommitted data*
- *Transaction processing systems*
- *Concurrency control with locking methods*
- *Two-phase locking to ensure serializability*
- *Concurrency control with time stamping methods*
- *Concurrency control with optimistic methods*
- *Recoverability*
- *Equivalence of schedules*
- *Testing for conflict serializability*

Introduction

A transaction is a logical unit of work. It begins, with the execution of a BEGIN TRANSACTION operation, and ends with the execution of a COMMIT or ROLLBACK operation. The logical unit of work that is, a transaction does not necessarily involve just a single database operation. Rather, it involves a sequence of several such operations as follows:

1. Database updates are kept in buffers in main memory and not physically written to disk until the transaction commits. That way, if the transaction terminates unsuccessfully, there will be no need to undo any disk updates.
2. Database updates are physically written to disk as part of the process of honouring the transaction's COMMIT request. That way if the system subsequently crashes, we can be sure that there will be no need to redo any disk updates.

Transactions and Concurrency Control

Database transactions reflect real-world transactions that are triggered by events, such as buying a product, registering for a course, or making a deposit in your checking account. Transactions are likely to contain many parts, for example, a sales transaction consists of at least two parts.

UPDATE inventory by subtracting number of units sold from the PRODUCT table's available quantity on hand and UPDATE the ACCOUNTS RECEIVABLE table in order to bill the CUSTOMER. All parts of a transaction must be completed to prevent data integrity problems. Therefore, executing and managing transactions are important database system activities.

Concurrency control is the management of concurrent transactions execution. When many users are able to access the database, the number of concurrent transactions tends to grow rapidly; as a result, concurrency control is especially important in multiuser database environments.

Transaction

A transaction is a logical unit of work that must be either entirely completed or aborted, no intermediate states are acceptable, that is, multicomponent transactions like the previously mentioned sale, must not be partially completed. If you read from and/or write to (update) the database, you create a transaction. Another example is using SELECT, to generate a list of table contents. Many real-world database transactions are formed by two or more database requests. A database request is the equivalent of a single SQL statement in an application program or transaction. Each database request generates several input/output operations. A transaction that changes the contents of a database must alter the database from one consistent state to another. A consistent database state is one in which all data integrity constraints are satisfied.

Example:

1. Checking an account balance:

   ```
   SELECT ACC_NUM, ACC_BALANCE
   FROM CHECKACC
   WHERE ACC_NUM = '0908110638';
   ```

   Even though we did not make any changes to the CHECKACC table, the SQL code represents a transaction, because we accessed the database.

2. Registering a credit sale of 100 units of product *X* to customer *Y* in the amount of \$500.00 first, product X's quantity on hand (QOH) needs to be reduced by 100.

   UPDATE PRODUCT
   SET PROD_QOH = PROD_QOH_100
   WHERE PROD_CODE = '*x*';
   Then, \$500 needs to be added to customer Y's accounts receivable
   UPDATE ACCT_RECEIVABLE
   SET ACCT_RECEIVABLE = ACCT_BALANCE + 500
   WHERE ACCT_NUM = '*Y*';

In Example 2, both the SQL, transactions must be completed in order to represent the real-world sales transaction. If both transactions are not completely executed, the transaction yields an inconsistent database.

If a transaction yields an inconsistent database, the DBMS must be able to recover the database to a previous consistent state.

Transaction Properties

All transactions must display atomicity, consistency, isolation and durability. These are known as ACID properties of transactions.

Atomicity

It requires that all operations of a transaction be completed; if not, the transaction is aborted. Therefore, a transaction is treated as a single, logical unit of work.

Consistency

It describes the result of the concurrent execution of several transactions. The concurrent transactions are treated as though they were executed in serial order. This property is important in multiuser and distributed database, where several transactions are likely to be executed concurrently.

Isolation

It means that the data used during the execution of a transaction cannot be used by a second transaction until the first one is completed. Therefore, if a transaction T_1 is being executed and is using the data item X_1, that data item cannot be accessed by any other transaction ($T_2 \dots T_n$) until T_1 ends. This property is particularly useful in multiuser database environment, because several different users can access and update the database at the same time.

Durability

It indicates the permanence of the database's consistent state. When a transaction is completed, the database reaches a consistent state, and that state cannot be lost, even in the event of the system's failure.

Transaction Management with SQL

The ISO standard defines a transaction model based on two SQL statements: COMMIT and ROLLBACK. The standard specifies that an SQL transaction automatically begins with a transaction-initiating SQL statement executed by a user or program (e.g., SELECT, INSERT, UPDATE). Changes made by a transaction are not visible to other concurrently executing transactions until the transaction completes. When a transaction sequence is initiated, it must continue through all succeeding SQL, statements until one of the following four events occur:

1. A COMMIT statement ends the transaction successfully, making the database changes permanent.
   A new transaction starts after COMMIT with the next transaction initiating statement.
2. For programmatic SQL, successful program termination ends the final transaction successfully, even if a commit statement has not been executed (equivalent to COMMIT)
3. For programmatic SQL, abnormal program termination aborts the transaction (equivalent to ROLLBACK)

Example:
UPDATE PRODUCT
SET PROD_QOH = PROD_QOH_100
WHERE PROD_CODE = '345TYX';

UPDATE ACCREC
SET AR_BALANCE = AR_BALANCE + 3500
WHERE AR_NUM = '60120010';
COMMIT;

Concurrency Control

The coordination of simultaneous execution of transactions in a multiprocessing database system is known as *concurrency control*. The objective of concurrency control is to ensure the serializability of transaction in a multiuser database environment. Concurrency is important, because the simultaneous execution of transactions over a shared database can create several data integrity and consistency problems. Three main problems are lost updates, uncommitted data and inconsistent retrievals.

Lost Updates

Consider the following two concurrent transactions where PROD_QOH represents a particular PRODUCT's quantity on hand. (PROD_QOH is an attribute in the Product table)

Assume the current PROD_QOH value for the product concerned is 35.

Table 1

Transaction	Computation
T_1: purchase 100 units	PROD_QOH = PROD_QOH + 100
T_2: sell 30 units	PROD_QOH = PROD_QOH – 30

Table 1 shows the serial execution of these transactions under normal circumstances, yielding the correct answer: PROD_QOH = 105. But suppose that a transaction is able to read a product's PROD_QOH value from the table before a previous transaction (using the same product) has been committed. The sequence depicted in Table 2 shows how the cost update problem can arise. Note that the first transaction (T_1) has not yet been committed when the second transaction (T_2) is executed. Therefore T_2 still operates on the value 135 to disk which is promptly over written by T_2. As a result, the addition of 100 units is "lost" during the process.

Uncommitted Data

Data are not committed when two transactions, T_1 and T_2 are executed concurrently and the first transaction (T_1) is rolled back after the second transaction (T_2) has already accessed the uncommitted data, thus violating the isolation property of transaction. Consider the same transactions from T_1 and T_2, from above. However, this time T_1 is rolled back to eliminate the addition of the 100 units. Because T_2 subtracts 30 from the original 35 units, the correct answer should be 5.

Table 2

	Computation
T_1: purchase 100 units	PROD_QOH = PROD_QOH + 100 (Rolled Back)
T_2: sell 30 units	PROD_QOH = PROD_QOH_30

Table 2 shows how, under normal circumstances, the serial execution of these transactions yield the correct answer. The uncommitted data problem can arise when the ROLLBACK is completed after T_2 has begun its execution.

Inconsistent Retrievals

Inconsistent retrievals occur when a transaction calculates some summary (aggregate) functions over a set of data, while other transactions are updating the data. The problem is that the transaction might read some data before they are changed and other data after they are changed, thereby yielding inconsistent results.

Example:

1. T_1 calculates the total PROD_QOH of the products stored in the PRODUCT table
2. At the same time, T_2 updates the PROD_QOH for two of the PRODUCT table's products (T_2 represents the correction of a typing error: the user added 30 units to product 345TYX's PROD_QOH but meant to add the 30 units to 125TYZ's PROD_QOH to correct the problem, the user subtracts 30 from product 345TYX's PROD_QOH and adds 30 to product 125TYZ's PROD_QOH).

The computed answer 485 is obviously wrong, because we know the correct answer to be 455.

Transaction Processing Systems

Transaction processing systems are systems with large databases and hundreds of concurrent users that are executing database transactions. For example, banking, credit card processing, stock markets, supermarket checkout, etc.

They require high availability and fast response time for hundreds of concurrent users.

1. A transaction includes one or more database access operations. These can include insertion, deletion, modification, or retrieval operations.
2. *Basic operations*: The basic database access operations that a transaction can include are as follows:
   - read_item (X): Reads a database item named X into a program variable.
   - Write_item (X): Writes the value of program variable X into the database item named X

Executing a read_item (X): Command includes the following steps:

1. Find the address of the disk block that contains item X
2. Copy that disk block into a buffer in main memory (if that disk block is not in main memory buffer).
3. Copy item X from the buffer to the program variable named x

Executing a write_item (X) command includes the following steps:

1. Find the address of the disk block that contains item X
2. Copy that disk block into a buffer in main memory (if that disk block is not in main memory buffer)
3. Copy item X from the program variable named X into its correct location in the buffer
4. Store the updated block from the buffer back to disk.

Step 4 actually updates the database on disk.

The decision about when to store back a modified disk block that is in a main memory buffer is handled by the recovery manager of the DBMS in cooperation with the underlying operating system.

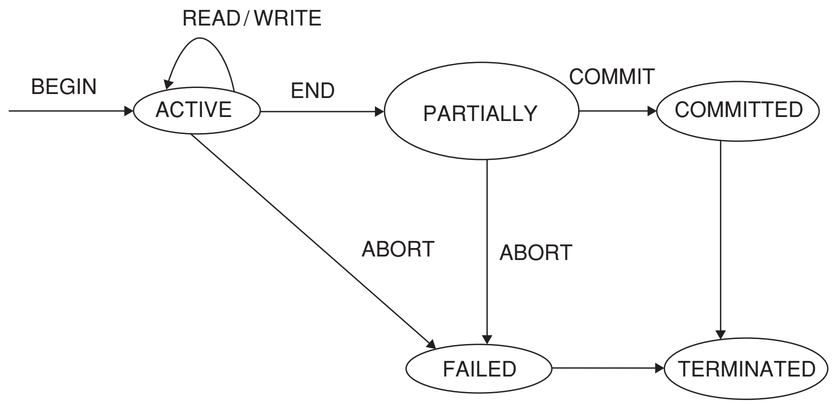

Figure 1 Transactions execution state transition diagram.

For the purpose of recovery, the system needs to keep track of when the transaction starts, terminates, and commits or aborts. Hence, the recovery manager keeps track of the following operations:

1. BEGIN_TRANSACTION: It shows the beginning of Execution of a transaction.
2. READ/WRITE: These specify read or write operations on the database items.
3. END_TRANSACTION: This specifies that READ and WRITE operations have ended and marks the end of transaction execution.
4. COMMIT_TRANSACTION: This shows a successful end of the transaction so that any changes executed by the transaction can be safely committed to the database and will not be undone.
5. ROLL BACK OR ABORT: This shows that the transaction has ended unsuccessfully, so that any changes or effects that the transaction may have applied to the database must be undone.
6. ACTIVE STATE: A transaction goes into an active state immediately after it starts execution where it can issue READ and WRITE operations.
7. PARTIALLY COMMITTED: When the transaction ends, it moves to the partially committed state
8. COMMIT: A transaction reaches its commit point when all its operations that access the database have been executed successfully, and the effect of all the transaction operations on the database have been recorded in the log. Beyond the commit point, the transaction is said to be committed, and its effect is assumed to be permanently recorded in the database.
9. FAILED_STATE: A transaction can go to the failed state if the transaction is aborted during its active state. The transaction may then have to be rolled back to undo the effect of its WRITE operations on the database.
10. TERMINATIED: The terminated state corresponds to the transactions leaving the system.

Concurrency Control with Locking Methods

A lock guarantees exclusive use of a data item to a transaction. In general, if transaction T_1 holds a lock on a data item (e.g., an employee's salary) then transaction T_2 does not have access to that data item. A transaction acquires a lock prior to data access; the lock is released (unlocked) when the transaction is completed, so that another transaction can lock the data item for its exclusive use. All lock information is managed by a lock manager, which is responsible for assigning and policing the locks used by the transactions.

Lock Granularity

Lock granularity indicates the level of lock use. Locking can take place at the following levels: database level, table level, page level, row level and field (or attribute) level.

Database Level

In a database-level lock, the entire database is locked, thus preventing the use of any tables in the database by transaction T_2 while transaction T_1 is being executed. Transaction T_1 and T_2 cannot access the database concurrently, even if they use different tables. This level of locking is suitable for batch processes, but it is not unsuitable for online multiuser DBMSs.

Table Level

In a table-level lock, the entire table is locked, preventing access to any row by transaction T_2 while transaction T_1 is using Table 2 transactions can access the same database, as long as they access different tables. Transactions T_1 and T_2 cannot access the same table even if they try to use different rows, T_2 must wait until T_1 unlocks the table.

Page level

In a page level lock, the DBMS will lock an entire disk page (a disk page or page is the equivalent of a disk block, which can

be described as a (referenced) section of a disk). Transactions T_1 and T_2 access the same table while locking different disk pages. If T_2 requires the use of a row located on a page that is locked by T_1, T_2 must wait until the page is unlocked by T_1.

Row level

The row-level lock is much less restrictive than the locks discussed earlier. The DBMS allows concurrent transactions to access different rows of the same table, even if the rows are located on the same page. A lock exists for each row in each table of the database.

Field level

The field-level lock allows concurrent transactions to access same row as long as they require the use of different fields (attributes) within the row. Although, field-level locking clearly yields the most flexible multi user data access, it requires a high level of computer over head.

Lock Types

1. Binary locks
2. Shared/Exclusive locks

Binary Locks

A binary lock has only two states: locked (1) or unlocked (0). If an object, that is, a database, table, page, or row is locked by a transaction, no other transaction can use that object. If an object is unlocked, any transaction can lock the object for its use. As a rule, a transaction must unlock the object after its termination. Every database operation requires that the affected object be locked. Therefore, every transaction requires a lock and unlock operation for each data item that is accessed. Such operations are automatically scheduled by the DBMS, the user need not concerned about locking or unlocking data items. Binary locks are now considered too restrictive to yield optimal concurrency conditions. For example if two transaction want to read the same database object, the DBMS will not allow this to happen, even though neither transaction updates the database (and therefore, no concurrency problems can occur) concurrency conflicts occur only when two transactions execute concurrently and one of them updates the database.

Shared/Exclusive locks

The tables "shared' and "exclusive" indicate the nature of the lock. The following table comparatively explains both locks.

Exclusive Locks	Shared Locks
An *exclusive lock* exists when access is specifically reserved for the transaction that locked the object.	A *shared lock* exists when concurrent transactions are granted READ access on the basis of a common lock.
The exclusive lock must be used when the potential for conflict exists.	A shared lock produces no conflict as long as the concurrent transactions are read only.
(An exclusive lock is issued when a transaction wants to write (update) a data item and no locks are currently held on that data item by any other transaction.	A shared lock is issued when a transaction wants to read data from the database and no exclusive lock is held on that data item.

Using the shared/exclusive locking concept, a lock can have three states: unlocked, shared (READ) and exclusive (WRITE). 2 READ transactions can be safely executed and shared locks allow several READ transactions to concurrently read the same data item. For example, if transaction T_1 has a shared lock on data item X, and transaction T_2 wants to read data item X, T_2 may also obtain a shared lock on data item X.

If transaction T_2 updates data item X, then an exclusive lock is required by T_2 over data item X. The exclusive lock is granted if and only if no other locks are held on the data item. Therefore, if a shared or exclusive lock is already held on data item X by transaction T_1, an exclusive lock cannot be granted to transaction T_2.

Potential problems with locks

Although locks prevent serious data inconsistencies, their use may lead to two major problems:

1. The resulting transaction schedule may not be serializable.
2. The schedule may create deadlocks. Database *deadlocks* are the equivalent of a traffic gridlock in a big city and are caused when *two transactions wait for each other to unlock data.*

Both problems can be solved. Serializability is guaranteed through a locking protocol known as two-phase locking and deadlocks can be eliminated by using deadlock detection, and prevention techniques. We shall examine these techniques next.

Two-phase Locking to Ensure Serializability

The *two-phase locking protocol* defines how transactions acquire and relinquish locks. It guarantees serializability, but it does NOT prevent deadlocks. The two phases are as follows:

1. A *growing phase*, in which a transaction acquires all the required locks without unlocking any data. Once all locks have been acquired, the transaction is in its locked point.
2. A *shrinking phase*, in which a transaction releases all locks and cannot obtain any new lock.

The two-phase locking protocol is governed by the following rules"

1. Two transactions cannot have conflicting locks.
2. No unlock operation can precede a lock operation in the same transaction.
3. No data are affected until all locks are obtained, that is, until the transaction is in its locked point.

DEADLOCKS

Deadlocks exist when two transactions, T_1 and T_2, exist in the following mode:

1. T_1 would like to access data item X and then data item Y. (So far, T_1 has locked data item X and T_1 is in progress, it will eventually require to lock data item Y.)
2. T_2 needs to access data items X and Y, to begin. (So far, T_2 has locked data item Y.)

If T_1 has not unlocked data item X, T_2 cannot begin; if T_2 has not unlocked data item Y, T_1 cannot continue. Consequently, T_1 and T_2 wait indefinitely, each waiting for the other to unlock the required data item. Such in a real-world DBMS, many transactions can be executed simultaneously, thereby increasing the probability of generating deadlocks. Note that deadlocks are possible only if one of the transactions wants to obtain an exclusive lock on a data item; no deadlock condition can exist among shared locks.

Three basic techniques exist to control deadlocks:

1. *Deadlock prevention*: A transaction requesting a new lock is aborted if there is a possibility that a deadlock can occur. If the transaction is aborted, all the changes made by this transaction are ROLLED BACK, and all locks obtained by the transaction are released. The transaction is then rescheduled for execution. Deadlock prevention works because it avoids the conditions that lead to deadlocking.
2. *Deadlock detection*: The DBMS periodically tests the database for deadlocks. If a deadlock is found, one of the transactions (the "victim") is aborted (ROLLED BACK and restarted), and the other transaction continues.
3. *Deadlock avoidance*: The transaction must obtain all the locks it needs before it can be executed.

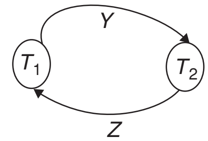
The best deadlock control method depends on the database environment. For example, if the probability of deadlocks is low, deadlock detection is recommended. However, if the probability of deadlocks is high, deadlock prevention is recommended. If response time is not high on the system priority list, deadlock avoidance might be employed.

Deadlock occurs when each transaction T in a set of two or more tractions is waiting for some item that is locked by some other transaction T^1 in the set. Each transaction in the set is on a waiting queue, waiting for one of the other transactions in the set to release the lock on an item

Example:

T_1	T_2
Write lock (z)	
	Read lock (z)
	Read lock (y)
Write lock (y)	

Transaction T_1 is waiting for Y which is locked by Transaction T_2 and transaction T_2 is waiting for z which is locked by transaction T_1. The below graph is called *wait for graph*.



Deadlock Prevention

There are number of deadlock prevention schemes that make a decision about what to do with a transaction involved in a possible deadlock situation:

1. Should it be blocked and made to wait
2. Should it be aborted
3. Should the transaction pre-empt and abort another transaction.

CONCURRENCY CONTROL WITH TIME STAMPING METHODS

The *time stamping* approach to scheduling concurrent transactions assigns a global unique time stamp to each transaction. The time stamp value produces an explicit order in which transactions are submitted to the DBMS. Time stamps must have two properties: uniqueness and monotonicity. *Uniqueness* ensures that no equal time stamp values can exist, and *monotonicity* ensures that time increases.

All database operations (READ and WRITE) within the same transaction must have the same time stamp. The DBMS executes conflicting operations in time stamp order, thereby ensuring serializability of the transactions. If two transactions conflict, one often is stopped, rescheduled, and assigned a new time stamp value.

The concept of transaction time stamp $TS(T)$, which is a unique identifier assigned to each transaction. The time stamps are based on the order in which transactions start. If transaction T_1 starts before transaction T_2, then $TS(T_1) < TS(T_2)$

1. Older transaction will have the smaller time stamp value
2. Two schemes that prevent deadlock are
   - Wait-die
   - Wound-wait

Suppose that transaction T_k tries to lock an item x but is not able to because x is locked by some other transaction T_L with a conflicting lock.

The rules followed by these schemes are as follows:

1. Wait-die: If T_s $(T_k) < T_s$ (T_L), then (T_k older than T_L) T_k is allowed to wait; otherwise (T_k younger than T_L) abort T_k and restart it later with the same time stamp
2. Wound-wait: If T_s $(T_k) < T_s$ (T_L) then (T_k older than T_L) abort T_L and restart it later with the same time stamp; otherwise (T_k younger than T_L) T_k is allowed to wait

Both schemes end up aborting the younger of the two transactions that may be involved in a deadlock

Concurrency Control with Optimistic Methods

Optimistic methods are based on the assumption that the majority of the database operations do not conflict. A transaction is executed without restrictions until it is committed. Each transaction moves through *two* or *three* phases:

Read phase: The transaction reads the database, executes the needed computations, and makes the updates to a private copy of the database values.

Validation phase: The transaction is validated to assure that the changes made will not affect the integrity and consistency of the database.

If the validation test is positive, transaction goes to the Write Phase.

If the validation test is negative, transaction is restarted, and changes are discarded.

Write phase: The changes are permanently applied to the database.

Serializability

Serializabilty is accepted as 'criterion for correctness' for the interleaved execution of a set of transactions, such an execution is considered to be correct if and only if it is serializable.

1. A set of transactions is serializable if and only if it is equivalent to some serial execution of the same transactions
2. A serial execution is one in which the transactions are run one at a time in some sequence

Schedule: Given a set of transactions, any execution of those transactions interleaved or otherwise is called a *schedule*.

1. Executing the transactions one at a time, with no interleaving constitutes a serial schedule. A schedule that is not serial is an interleaved schedule (or) non-serial schedule.
2. Two schedules are said to be equivalent if and only if they are guaranteed to produce the same result as each other. Thus, a schedule is serializable, and correct, if and only if it is equivalent to some serial schedule.

Two-phase Locking Theorem

If all transactions obey the two phase locking protocol, then all possible interleaved schedule are serializable.

1. Before operating on any object (it could be a database tuple), a transaction must acquire a lock on the object
2. After releasing a lock, a transaction must never go on to acquire any more locks.

A transaction that obeys this protocol thus has two phases: a lock acquisition or "growing phase and a lock releasing or "shrinking" phase

Let '*I*' be an interleaved schedule involving some set of transactions $T, T_2, T_3, \ldots T_n$.

If '*I*' is serializable, then there exists at least one serial schedule '*S*' involving $T_1, T_2, \ldots T_n$ such that '*I*' is equivalent to '*S*' is said to be a serialization of '*I*'

Let T_i and T_j be any two distinct transactions in the set $T_1, T_2, T_3, \ldots T_n$. Let T_i precede T_j in the serialization '*S*'. In the interleaved schedule *I*, then the effect must be as if T_i really did execute before T_j. In other words, if *A* and *B* are any two transactions involved is some serializable schedule, then either A logically precedes *B* or *B* logically precedes *A* in that schedule, that is, either *B* can see A's output or *A* can see B's. If the effect is not as if either A ran before *B* or *B* ran before A, then the schedule is not serializable and not correct.

1. A schedule '*S*' of '*n*' transactions $T_1, T_2 \ldots T_n$ is an ordering of the operations of the transactions subject to the constraint that, for each transaction T_i that participates in '*S*', the same order in which they occur in T_i.
2. For the purpose of recovery and concurrency control, we are mainly interested in the 'read item' and 'write item' operations of the transactions, as well as the COMMIT and ABORT operations. A shorthand notation for describing a schedule uses the symbols, '*R*', '*W*', '*C*' and 'A' for the operations read item, write item, commit, and abort respectively, and appends as subscript the transition-id (transaction number) to each operation in the schedule

Example: The schedule of the given set of transactions can be written as follows:

T_1	T_2
Read item (x);	
$X = X - N$;	
	Read item (x);
	$X = X + M$;
Write item (x)	
Read item (y)	
	Write item (x)
	Write item (y)
$Y = Y + N$	
Write item (y)	Commit

Schedule:

$$S: R_1(X); R_2(X); W_1(X); R_1(Y); W_2(X); W_2(Y); W_1(Y); C_2$$

Conflicts: Two operations in a schedule are said to have conflict if they satisfy all three conditions, if

1. they belong to different transactions
2. they access the same data item
3. at least one of the operations is a write item

For example, In the schedule 'S' given above, the operations $r_1(x)$ and $w_2(x)$ conflict, as do

The operations $r_2(x)$ and $w_1(x)$ and the operations $w_1(x)$ and $w_2(x)$. However the operations $r_1(x)$ and $r_2(x)$ do not conflict, since they are both read operations;

The operations $w_1(x)$ and $w_2(y)$ do not conflict because they operate on distinct data items x and y. The operations $r_1(x)$ and $w_1(x)$ do not conflict, because they belong to the same transaction.

Complete schedule: A schedule S of 'n' transactions T_1, T_2, $T_3 \ldots T_n$ is said to be a complete schedule if the following conditions hold.

1. The operations is 'S' are exactly those operations in $T_1, T_2, \ldots T_n$ including a commit or abort operation as the last operation for each transaction in the schedule.
2. For any pair of operations from the same transaction T_i, their order of appearance in 'S' is the same as their order of appearance in T_i
3. For any two conflicting operations, one of the two must occur before the other in the schedule.

The preceding condition (3) allows for two non-conflicting operations to occur in the schedule without defining which occurs first, thus leading to the definition of a schedule as a partial order of the operations in the 'n' transactions.

It is difficult to encounter complete schedules in a transaction processing system, because new transactions are continually being submitted to the system. Hence, it is useful to define the concept of the 'committed projection $C(S)$ of schedule S; which include only the operations in S that belong to committed transactions, that is, transaction T_i whose commit operation is C_i.

Recoverability

Recoverability ensures that once a transaction T is committed, it should never be necessary to roll back T. The schedules that theoretically meet this criterion are called *recoverable schedules* and those that do not are called *non-recoverable*, and hence should not be permitted

A schedule 'S' is recoverable if no transaction T in 'S' commits until all transactions T^1 that have written an item that T reads have committed

A transaction T reads from transaction T^1 in a schedule S if some item x is first written by T^1 and later read by T. In addition, T^1 should not have been aborted before T reads item x, and there should be no transactions that write x after T^1 writes it and before T reads it (unless those transactions, if any, have aborted before T reads x)

Example:
Consider the given schedule, check whether it is recoverable or not:
S: $R_1(X)$; $R_2(X)$; $W_1(X)$; $R_1(Y)$; $W_2(X)$; C_2, $W_1(Y)$; C_1?

Solution:
The given schedule can also be represented as follows:

T_1	T_2
$R_1(x)$	
	$R_2(x)$
$W_1(x)$	
$R_1(y)$	
	$W_2(x)$
	C_2
$W_1(y)$	
C_1	

There are two *WR* conflicts, if the schedule consists of *RW* conflict, then we may say that the schedule is not recoverable (if the transaction which is performing read operation commits first)

Cascadeless Schedule

In a recoverable schedule, no committed transaction ever needs to be rolled back. It is possible for a phenomenon known as cascading rollback to occur, when an uncommitted transaction has to be rolled back because it read an item from a transaction that failed.

This is illustrated in the following schedule:

Example:
S: $R_1(X)$; $W_1(X)$; $R_2(X)$; $R_1(Y)$; $W_2(X)$; $W_1(Y)$; A_1, A_2
The above schedule is represented as follows:

T_1	T_2
$R_1(x)$	
$W_1(x)$	
	$R_2(x)$
$R_1(y)$	
	$W_2(x)$
$W_1(y)$	
A_1	
	A_2

Transaction T_2 has to be rolled back because it reads item x from T_1, and T_1 is then aborted, because cascading rollback

can be quite time consuming since numerous transactions can be rolled back. It is important to characterize the schedules where this phenomenon is guaranteed not to occur.

A scheduled is said to be cascadeless if every transaction in the schedule reads only items that were written by committed transaction. In this case, all items read will not be discarded, so no cascading rollback will occur.

Strict Schedule

A schedule is called *strict schedule*, in which transactions can neither read nor write an item x until the last transaction that wrote x has committed or aborted

1. All strict schedules are cascadeless
2. All cascadeless schedules are recoverable

Equivalence of Schedules

There are several ways to define equivalence of schedules as follows:

1. Result equivalent
2. Conflict equivalent
3. View equivalent

Result Equivalent

Two schedules are called *result equivalent* if they produce the same final state of the database. However, two different schedules may accidentally produce the same final state.

Example: Check whether the two schedules are result equivalent or not:

S_1	S_2
Read item (x);	Read item (x)
$X = X + 20$;	$X = X * 1.1$;
Write item (x);	Write item (x);

Solution:
Schedules S_1 and S_2 will produce the same final database state if they execute on a database with an initial value of $x = 200$; but for other initial values of x, the schedules are not result equivalent

For two schedules to be equivalent, the operations applied to each data item affected by the schedules should be applied to that item in both schedules in the same order. The other two definitions of equivalence of schedules generally used are conflict equivalence and view equivalence

Conflict Equivalence

Two schedules are said to be conflict equivalent if the order of any two conflicting operations is the same in both schedules. If two conflicting operations are applied in different orders in two schedules, the effect can be different on the database or on other transactions in the schedule, and hence the schedules are not conflict equivalent.

Example:

S_1	
$r_1(x)$	
	$W_2(x)$

S_3	
$W_1(x)$	
	$W_2(x)$

S_2	
	$W_2(x)$
$r_1(x)$	

S_4	
	$W_2(x)$
$W_1(x)$	

The value read by $r_1(x)$ can be different in the two schedules. Similarly, if two write operations occur in the order $w_1(x)$, $w_2(x)$ in s_3, and in the reverse order $w_2(x)$, $w_1(x)$ in s_4, the next $r(x)$ operation in the two schedules will read potentially different values.

Testing for Conflict Serializability

The following algorithm can be used to test a schedule for conflict serializability. The algorithm takes read item and write item operations in a schedule to construct a precedence graph or serialization graph, which is a directed graph $G(N, E)$ here N is a set of Nodes $N = \{T_1, T_2, \ldots. T_n\}$ and E is a set of directed edges $E = \{e_1, e_2, \ldots.. E_m\}$ There is one node in the graph for each transaction. T_i in the schedule. Each edge e_i in the graph is of the form $(T_j \rightarrow T_k)$, 1 ″ j ″ n, 1 ″ k ″ n,

Where T_j is the starting node of e_i and T_k is the ending node of e_i.

Edge is created if one of the operations in T_j appears in the schedule before some conflicting operation in T_k

Algorithm

1. For each transaction T_i participating in schedule S, create a node labelled T_i in the precedence graph
2. For each case in S where T_j executes a read item (x) after T_i executes a write item (x), create an edge ($T_i \rightarrow T_j$) in the graph
3. For each case in S where T_j executes a write item (x) after T_i executes a read item (x), create an edge ($T_i \rightarrow T_j$) in the graph
4. For each case in S where T_j executes a write item (x) after T_i executes a write item (x), create an edge ($T_i \rightarrow T_j$) in the precedence graph
5. The schedule S is serializable, if the precedence graph contains no cycles

A cycle in a directed graph is a sequence of edges $C = ((T_j \rightarrow T_k), (T_k \rightarrow T_p), \ldots (T_i \rightarrow T_j))$

With the property that the starting node of each edge, except the first edge is the same as the ending node of the previous edge, and the starting node of the first edge is the same as the ending node of the last edge.

Example: Check whether the given schedule is conflict serializable or not by drawing precedence graph:

T_1	T_2	T_3
$R_1(x)$		
	$W_2(x)$	
		$R_3(x)$
$W_1(x)$		
		$W_3(x)$
$R_1(x)$		

Solution:

First identify the conflicts:

$(T_1 \rightarrow T_2)$ WR conflict

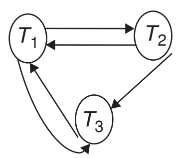
$(T_2 \rightarrow T_1)$ WW conflict

$(T_2 \rightarrow T_3)$ RW conflict

$(T_3 \rightarrow T_1)$ WR conflict

$(T_1 \rightarrow T_3)$ WW conflict

Take transactions as nodes in the precedence graph:



The precedence graph has cycle, which says that the schedule is not serializable.

View Equivalence and View Serializability

View equivalence is less restrictive compared to conflict equivalence. Two schedules S and S' are said to be view equivalent if the following three conditions hold:

1. The same set of transactions participate in S and S', and S and S' include the same operations of those transactions
2. For any operation $r_i(x)$ of T_i in S, if the value of x read by the operation has been written by an operation $w_j(x)$ of T_j, the same condition must hold for the value of x read by operation $r_i(x)$ of T_j in S'
3. If the operation $w_k(y)$ of T_k is the last operation to write Y in S, then $W_k(y)$ of T_k must also be the last operation to write item Y in S'

The idea behind view equivalence is that as long as each read operation of a transaction reads the result of the same write operation in both schedules, the write operations of each transaction must produce the same result. Hence the read operation is said to see the same view in both schedules:

1. A schedule S is said to be view serializable if it is view equivalent to a serial schedule.
2. All conflict serializable schedules are view serializable, but vice versa is not true.

Exercises

Practice Problem 1

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider the given schedules S_1 and S_2

S_1: $r_1(x)$, $r_1(y)$, $r_2(x)$, $r_2(y)$, $w_2(y)$, $w_1(x)$

S_2: $r_1(x)$, $r_2(x)$, $r_2(y)$, $w_2(y)$, $r_1(y)$, $w_1(x)$

Which schedule is conflict serializable?

(A) S_1 (B) S_2
(C) S_1 and S_2 (D) None of these

2. Consider the given schedule with three transactions T_1, T_2 and T_3:

T_1	T_2	T_3
$r_1(x)$		
	$r_2(y)$	
		$r_3(y)$
	$w_2(y)$	
$w_1(x)$		
		$w_3(x)$
	$r_2(x)$	
	$w_2(x)$	

Which of the following is correct serialization?

(A) $T_2 \rightarrow T_1 \rightarrow T_3$ (B) $T_1 \rightarrow T_3 \rightarrow T_2$
(C) $T_3 \rightarrow T_1 \rightarrow T_2$ (D) None of these

3. Consider the three data items D_1, D_2 and D_3 and the following execution of schedules of transactions T_1, T_2 and T_3:

T_1	T_2	T_3
	$R(D_2)$	
	$R(D_2)$	
	$W(D_2)$	
		$R(D_2)$
		$R(D_3)$
$R(D_1)$		
$W(D_1)$		
		$W(D_2)$
		$W(D_3)$
	$R(D_1)$	
$R(D_2)$		
$W(D_2)$		
	$W(D_1)$	

Which of the following is true?

(A) The schedule is conflict serializable
(B) The schedule is not conflict serializable
(C) The schedule has deadlock
(D) Both (A) and (C)

4. Consider the given schedule

T_3	T_4	T_7
$R(Q)$		
	$W(Q)$	
$W(Q)$		
		$R(Q)$
		$W(Q)$

Which of the following is the correct precedence graph for the above schedule?

(A) 
(B) 
(C) 
(D) 
5. Consider two Transactions T_1 and T_2 and four schedules: S_1, S_2, S_3 and S_4 of T_1 and T_2:

T_1: $r_1(x), w_1(x), w_1(y)$

T_2: $r_2(x), r_2(y), w_2(y)$

S_1: $r_1(x), r_2(x), r_2(y), w_1(x), w_1(y), w_2(y)$

S_2: $r_1(x), r_2(x), r_2(y), w_1(x), w_2(y), w_1(y)$

S_3: $r_1(x), w_1(x), r_2(x), w_1(y), r_2(y), w_2(y)$

S_4: $r_2(x), r_2(y), r_1(x), w_1(x), w_1(y), w_2(y)$

Which schedules are conflict serializable in the given schedules?

(A) S_1 and S_2
(B) S_1 and S_3
(C) S_2 and S_3
(D) S_1 and S_4

6. Consider the following transactions with data items P and Q initialized to '0':

T_1: read(P)

Read(Q)

if $p = 0$ then $Q = Q + 1$

Write(Q)

T_2: read(Q)

Read(P)

if $Q = 0$ then $p = p + 1$

Write (P)

Any non-serial interleaving of T_1 and T_2 for concurrent execution leads to

(A) a serializable schedule
(B) a schedule that is not conflict serializable
(C) a conflict serializable schedule
(D) a schedule for which a precedence graph cannot be drawn

7. Consider the concurrent execution of two transactions T_1 and T_2, if the initial values of x, y, M and N are 200, 100, 10, 20 respectively. What are the final values of x and y?

T_1	T_2
read-item(x)	
$x = x - N$	
	read-item(x)
	$x = x + M$
Write-item(x)	
read-item(y)	
	Write-item(x)
$y = y + N$	
Write-item(y)	

(A) 220, 110 (B) 210, 120
(C) 220, 120 (D) 210, 110

8. For the above data, if the transactions are executed in serial manner, what would be the values of X and Y at the end of the serial execution of T_1 and T_2?

T_1	T_2
Read-item(x)	
$X = X - N$	
Write-item(x)	
Read-item(y)	
$Y = Y + N$	
Write-item(y)	
	Read-item(x)
	$X = X + M$
	Write-item(x)

(A) 190, 120
(B) 180, 120
(C) 190, 110
(D) 180, 110

9. Consider the given two transactions T_1 and T_2:

T_1: $r_1(x), w_1(x), r_1(y)$

T_2: $r_2(x), r_2(y), w_2(x), w_2(y)$

Which of the following schedules are complete schedules?

(A) $r_1(x), r_2(x), w_1(x), r_1(y), r_2(y), w_2(x), w_2(y)$
(B) $r_2(x), r_1(x), r_2(y), w_1(x), w_2(x), r_1(y), w_2(y)$
(C) $r_1(x), r_1(y), r_2(x), r_2(y), w_1(x), w_2(x), w_2(y)$
(D) All the above

10. Consider the given schedule with data-locks on data-items, check whether it has dead-lock or not. The locks are shared-lock(S) and Exclusive-lock(X). Shared-lock is also called Read-lock, Exclusive-lock is also called Write-lock. Read and Write operations are denoted by *R* and *W*, respectively.

T_1	T_2	T_3	T_4
S(A)			
R(A)			
	X(B)		
	W(B)		
S(B)			
		S(C)	
		R(C)	
	X(C)		
			X(B)
		X(A)	

Which of the following is incorrect?

(A) $T_1 \rightarrow T_2$ (B) $T_3 \rightarrow T_1$
(C) $T_2 \rightarrow T_3$ (D) $T_4 \rightarrow T_3$

11. Consider the three transactions T_1, T_2 and T_3 and the schedule S_1 as given below. Draw the serializability (precedence) graph for S_1, and state whether the schedule is serializable or not. If a schedule is serializable, which one of the following is equivalent serial schedule?

T_1: $r_1(x), r_1(z), w_1(x)$
T_2: $r_2(z), r_2(y), w_2(z), w_2(y)$
T_3: $r_3(x), r_3(y), w_3(y)$

S_1: $r_1(x), r_2(z), r_1(z), r_3(x), r_3(y), w_1(x), w_3(y), r_2(y), w_2(z), w_2(y)$?

(A) $r_3(x), r_3(y), w_3(y), r_1(x), r_1(z), w_1(x), r_2(z), r_2(y), w_2(z), w_2(y)$
(B) $r_1(x), r_1(z), w_1(x), r_2(z), r_2(y), w_2(z), w_2(y), r_3(x), r_3(y), w_3(y)$
(C) $r_2(z), r_2(y), w_2(z), w_2(y), r_3(x), r_3(y), w_3(y), r_1(x), r_1(z), w_1(x)$
(D) $r_2(z), r_2(y), w_2(z), w_2(y), r_1(x), r_1(z), w_1(x), r_3(x), r_3(y), w_3(y)$

12. Consider the data given in the above question. Draw the precedence graph for S_2 and state whether each schedule is serializable or not. If a schedule is serializable, which of the following is equivalent serial schedule?

S_2: $r_1(x), r_2(z), r_3(x), r_1(z), r_2(y), r_3(y), w_1(x), w_2(z), w_3(y), w_2(y)$

(A) $r_3(x), r_3(y), w_3(y), r_1(x), r_1(z), w_1(x), r_2(z), r_2(y), w_2(z), w_2(y)$
(B) $r_1(x), r_1(z), w_1(x), r_2(z), r_2(y), w_2(z), w_2(y), r_3(x), r_3(y), w_3(y)$
(C) $r_2(z), r_2(y), w_2(z), w_2(y), r_3(x), r_3(y), w_3(y), r_1(x), r_1(z), w_1(x)$
(D) $r_2(z), r_2(y), w_2(z), w_2(y), r_1(x), r_1(z), w_1(x), r_3(x), r_3(y), w_3(y)$

13. Consider schedule S_3, which is a combination of transactions T_1, T_2 and T_3 from Q. No.11.

S_3: $r_1(x), r_2(z), r_1(z), r_3(x), r_3(y), w_1(x), c_1, w_3(y), c_3, r_2(y), w_2(z), w_2(y), c_2$?

Which of the following is true?

(A) Recoverable and conflict serializable
(B) Recoverable but not conflict serializable
(C) Conflict serializable but not Recoverable
(D) Not recoverable and not conflict serializable

14. Consider the given schedule:

S_4: $r_1(x), r_2(z), r_1(z), r_3(x), r_3(y), w_1(x), w_3(y), r_2(y), w_2(z), w_2(y), c_1, c_2, c_3$:

Which of the following is true?

(A) Recoverable and conflict serializable
(B) Recoverable but not conflict serializable
(C) Conflict serializable but not Recoverable
(D) Not recoverable and not conflict serializable

15. Which of the following is correct for the below compatibility matrix?

Mode of Locks Currently held by other transactions		**Shared-Lock**	**Exclusive-Lock**
	S		
	X		

S – shared - Lock, X – Exclusive - Lock

(A)

	S	X
S	No	No
X	Yes	No

(B)

	S	X
S	Yes	No
X	No	No

(C)

	S	X
S	Yes	Yes
X	No	No

(D)

	S	X
S	No	Yes
X	No	No

16. Consider the following schedule with locking:

T_1	T_2
Lock – $X(A)$	
$R(A)$	
$W(A)$	
	Lock – $X(B)$
	$R(B)$
	$W(B)$
	Lock – $X(A)$
Lock – $X(B)$	

Which of the following is true?
(A) schedule is in Dead–Lock state
(B) schedule is conflict serializable
(C) schedule is not conflict serializable
(D) Both A and B

17. Consider the given set of transactions:

T_1	T_2
	SELECT AVG (balance)
	FROM Account
INSERT INTO Account	
VALUES (487, 2000);	
COMMIT	
	SELECT AVG (balance)
	FROM Account
	COMMIT

The above problem is a case of
(A) READ UNCOMMITTED
(B) RAD COMMITTED
(C) REPEATABLE READ
(D) DIRTY READ

18. Consider the given set of transactions

T_1	T_2
UPDATE ACCOUNT	
SET balance = balance – 1000	
WHERE number = 586;	
	SELECT AVG (balance)
	FROM Account
ROLL BACK	
	COMMIT

The above problem is a case of
(A) READ UNCOMMITTED
(B) READ COMMITTED
(C) DIRTY READ
(D) BOTH A and C

19. Consider the following set of transactions

T_1	T_2
	SELECT AVG (balance)
	FROM Account
UPDATE Account	
SET balance = balance – 4000	
WHERE number = 586;	
COMMIT	
	SELECT AVG (balance)
	FROM Account
	COMMIT

The above problem is a case of
(A) READ UNCOMMITTED
(B) READ COMMITTED
(C) REPEATABLE READ
(D) DIRTY READ

20. Consider the following schedule with locks on data items:

T_1	T_2	T_3
$X(A)$		
	$X(A)$	
		$X(A)$
$S(B)$		
	$S(B)$	

Which of the following is incorrect?
(A) $T_2 \rightarrow T_1$
(B) $T_3 \rightarrow T_2$
(C) $T_3 \rightarrow T_1$
(D) $T_1 \rightarrow T_3$

Practice Problem 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Which of the following is false with respect to B^+ -trees of order p?
(A) Each internal node has at most p tree pointers.
(B) Each leaf node has at most $\left\lceil \left(\frac{p}{2}\right) \right\rceil$ values.
(C) Each internal node, except the root, has at least $\left\lceil \left(\frac{p}{2}\right) \right\rceil$ tree pointers.
(D) All leaf nodes are at same level.

2. Consider below transactions:

T_1	T_2
Read – item(X);	
$X := X - N$;	
	Read – item (X);
	$X := X + M$;
Write – item(X);	
Read – item (Y);	
	Write – item (X);
$Y := Y + N$;	
Write – item (Y);	

Which of the following problem will occur during the concurrent execution of the above transactions?

(A) Lost update problem because of incorrect X.
(B) Lost update problem because of incorrect Y.
(C) Dirty read problem because of incorrect X.
(D) Dirty read problem because of incorrect Y.

3. Consider the scheduled:

S: $r_1(X)$; $r_2(X)$; $w_1(X)$; $r_1(Y)$; $w_2(X)$; C_2; $w_1(Y)$; C_1;

This schedule is

(A) Recoverable (B) Non-recoverable
(C) Strict schedule (D) Both (A) and (C)

4. Consider below schedule:

T_1	T_2
Read – item(X);	
$X := X - N$;	
	Read – item (X);
	$X := X + M$;
Write – item(X);	
Read – item (Y);	
	Write – item (X);
$Y := Y + N$;	
Write – item (Y);	

This schedule is

(A) Serializable
(B) Not serializable
(C) Under dead lock
(D) Both (B) and (C)

5. Let, current number of file records = r

maximum number of records = bfr

current number of file buckets = N

Then what will be the file load factor?

(A) $\frac{r}{(bfr * N)}$ (B) $r + (bfr * N)$

(C) $r * (bfr * N)$ (D) $r * (bfr + N)$

6. Match the following:

	LIST I		LIST II
1.	Primary index	A.	Ordered key field
2.	Clustering index	B.	Non-ordered field
3.	Secondary index	C.	Ordered non-key field

(A) 1 – A, 2 – B, 3 – C
(B) 1 – A, 2 – C, 3 – B
(C) 1 – C, 2 – B, 3 – A
(D) 1 – C, 2 – A, 3 – B

7. Consider a file with 30,000 fixed length records of size 100 bytes stored on a disk with block size 1024 bytes. Suppose that a secondary index on a non-ordering key field is constructed with key field size 9 bytes and block pointer 6 bytes. What will be the number of blocks needed for the index?

(A) 68 (B) 442
(C) 1500 (D) 3000

8. Match the following:

	Index type		Number of Index entries
1.	Primary Index	A.	Blocks in data file
2.	Clustering index	B.	Record in data file
3.	Secondary key index	C.	Distinct index filed values

(A) 1 – A, 2 – B, 3 – C (B) 1 – A, 2 – C, 3 – B
(C) 1 – C, 2 – B, 3 – A (D) 1 – C, 2 – A, 3 – B

9. Which of the following is true with respect to B – Tree of order p?

(A) Each node has at most p tree pointers.
(B) Each node, except the root and leaf nodes, has at least $\left\lceil \frac{p}{2} \right\rceil$ tree pointers.
(C) All leaf nodes are at the same level.
(D) All of these.

10. What is the amount of unused space in allocation of unspanned fixed records of size R on a block of size B bytes?

(A) $B - R$ (B) $B - \left\lfloor \frac{B}{R} \right\rfloor$

(C) $B - \left(\left\lfloor \frac{B}{R} \right\rfloor * R\right)4$ (D) $\left(\left\lfloor \frac{B}{R} \right\rfloor * R\right) - B$

11. What is the average time required to access a record in a file consisting of b blocks using unordered heap linear search?

(A) b (B) $b/2$
(C) $\log_2^b$ (D) b^2

12. Consider a file of fixed length records of size R bytes. If the block size is B bytes, then the blocking factor will be

(A) $B \times R$ records (B) $\left\lfloor \frac{B}{R} \right\rfloor$ records

(C) $\left\lceil \frac{B}{R} \right\rceil$ records (D) $B + R$ records

13. Consider the following relation instance:

P	Q	R
1	4	2
1	5	3
1	6	3
3	2	2

Which of the following FDs are satisfied by the instance?

(A) $PQ \rightarrow R$ and $R \rightarrow Q$ (B) $QR \rightarrow P$ and $Q \rightarrow R$

(C) $QR \rightarrow P$ and $P \rightarrow R$ (D) $PR \rightarrow Q$ and $Q \rightarrow P$

14. Consider an ordered file with 30,000 records stored on a disk with block size of 1024 bytes. The records are of fixed size and are of unspanned, with record length 100 bytes. What is the number of accesses required to access a data file using binary search?

(A) 10 (B) 12

(C) 1500 (D) 3000

15. What is the blocking factor for an index if the ordering key field size is 9 bytes and block pointer is 6 bytes long, and the disk block size is 1024 bytes?

(A) 114 (B) 171

(C) 341 (D) 68

16. For a set of n transactions, there exist ______ different valid serial schedules

(A) n (B) n^2

(C) $n/2$ (D) $n!$

17. The number of possible schedules for a set of n transactions is

(A) lesser than $n!$ (B) much larger than $n!$

(C) $n!$ (D) None

18. Which one of the following is conflict operation?

(A) Reads and writes from the same transaction

(B) Reads and writes from different transaction

(C) Reads and writes from different transactions on different data items.

(D) Reads and writes from different transaction on same data.

19. The following schedule S: $r_3(x), r_2(x), w_3(x), r_1(x), w_1(x)$ is conflict equivalent to serial schedule

(A) $T_1 \rightarrow T_3 \rightarrow T_1$ (B) $T_2 \rightarrow T_1 \rightarrow T_3$

(C) $T_1 \rightarrow T_2 \rightarrow T_3$ (D) None

20. The following schedule S: $R_1(x), R_2(x), W_1(x), W_2(x)$ is

(A) Conflict serializable (B) View serializable

(C) Both (D) None

Previous Years' Questions

1. Consider the following four schedules due to three transactions (indicated by the subscript) using *read* and *write* on a data item x, denoted by $r(x)$ and $w(x)$, respectively. Which one of the them is conflict serializable? **[2014]**

(A) $r_1(x); r_2(x); w_1(x); r_3(x); w_2(x)$

(B) $r_2(x); r_1(x); w_2(x); r_3(x); w_1(x)$

(C) $r_3(x); r_2(x); r_1(x); w_2(x); w_1(x)$

(D) $r_2(x); w_2(x); r_3(x); r_1(x); w_1(x)$

2. Consider the following schedule S of transactions T_1, T_2, T_3, T_4:

T_1	T_2	T_3	T_4
	Reads (X)		
		Writes (X) Commit	
Writes (X) Commit			
	Writes (Y) Reads (Z) Commit		
			Reads (X) Reads (Y) Commit

Which one of the following statements is correct? **[2014]**

(A) S is conflict-serializable but not recoverable

(B) S is not conflict-serializable but is recoverable

(C) S is both conflict-serializable and recoverable

(D) S is neither conflict-serializable nor it is recoverable

3. Consider the following transaction involving two bank accounts x and y.

read (x) ; $x := x - 50$; write (x) ; read(y); $y := y + 50$; write(y)

The constraint that the sum of the accounts x and y should remain constant is that of **[2015]**

(A) Atomicity (B) Consistency

(C) Isolation (D) Durability

4. Consider a simple checkpointing protocol and the following set of operations in the log.

(start, T_4); (write, T_4, y, 2, 3); (start, T_1); (commit, T_4); (write, T_1, z, 5, 7);

(checkpoint);

(start, T_2); (write, T_2, x, 1, 9); (commit, T_2); (start, T_3), (write, T_3, z, 7, 2);

If a crash happens now and the system tries to recover using both undo and redo operations. What are the contents of the undo list and the redo list? **[2015]**

(A) Undo: T_3, T_1; Redo: T_2
(B) Undo: T_3, T_1; Redo: T_2, T_4
(C) Undo: none; Redo: T_2, T_4, T_3, T_1
(D) Undo: T_3, T_1, T_4; Redo: T_2

5. Consider the following partial schedule S involving two transactions T_1 and T_2. Only the read and the write operations have been shown. The read operation on data item P is denoted by read(P) and the write operation on data item P is denoted by write(P)

Time Instance	Transaction – id	
	T_1	T_2
1	read(A)	
2	write(A)	
3		read(C)
4		write(C)
5		read(B)
6		write(B)
7		read(A)
8		commit
9	read(B)	

Schedule S

Suppose that the transaction T_1 fails immediately after time instance 9. Which one of the following statements is correct? **[2015]**

(A) T_2 must be aborted and then both T_1 and T_2 must be re-started to ensure transaction atomicity.
(B) Schedule S is non-recoverable and cannot ensure transaction atomicity.
(C) Only T_2 must be aborted and then re-started to ensure transaction atomicity.
(D) Schedule S is recoverable and can ensure atomicity and nothing else needs to be done.

6. Which one of the following is **NOT** a part of the ACID properties of database transactions? **[2016]**

(A) Atomicity
(B) Consistency
(C) Isolation
(D) Deadlock - freedom

7. Consider the following two phase locking protocol. Suppose a transaction T accesses (for read or write operations), a certain set of objects $\{O_1, \ldots, O_k\}$. This is done in the following manner: **[2016]**

Step 1. T acquires exclusive locks to $O_1, \ldots O_k$ in increasing order of their addresses.

Step 2. The required operations are performed.

Step 3. All locks are released.

This protocol will

(A) guarantee serializability and deadlock-freedom.
(B) guarantee neither serializability nor deadlock-freedom.
(C) guarantee serializability but not deadlock-freedom.
(D) guarantee deadlock-freedom but not serializabilty.

8. Suppose a database schedule S involves transactions $T_1, \ldots T_n$. Construct the precedence graph of S with vertices representing the transactions and edges representing the conflicts. If S is serializable, which one of the following orderings of the vertices of the precedence graph is guaranteed to yield a serial schedule? **[2016]**

(A) Topological order
(B) Depth - first order
(C) Breadth - first order
(D) Ascending order of transaction indices

9. Consider the following database schedule with two transactions T_1 and T_2.

$S = r_2(X); r_1(X); r_2(Y); w_1(X); r_1(Y); w_2(X); a_1; a_2$

Where $r_i(Z)$ denotes a *read* operation by transaction T_i on a variable Z, $w_i(Z)$ denotes a *write* operation by T_i on a variable Z and *ai* denotes an *abort* by transaction T_i.

Which one of the following statements about the above schedule is **TRUE**? **[2016]**

(A) S is non - recoverable
(B) S is recoverable, but has a cascading abort
(C) S does not have a cascading abort
(D) S is strict.

10. In a database system, unique timestamps are assigned to each transaction using Lamport's logical clock. Let $TS(T_1)$ and $TS(T_2)$ be the timestamps of transactions T_1 and T_2 respectively. Besides, T_1 holds a lock on the resource R, and T_2 has requested a conflicting lock on the same resource R. The following algorithm is used to prevent deadlocks in the database system assuming that a killed transaction is restarted with the same timestamp.

if $TS(T_2) < TS(T_1)$ then
    T_1 is killed
else T_2 waits.

Assume any transaction that is not killed terminates eventually. Which of the following is TRUE about the database system that uses the above algorithm to prevent deadlocks? **[2017]**

(A) The database system is both deadlock-free and starvation-free.
(B) The database system is deadlock-free, but not starvation-free.

(C) The database system is starvation-free, but not deadlock-free.
(D) The database system is neither deadlock-free nor starvation-free.

11. Two transactions T_1 and T_2 are given as

$$T_1 : r_1(X)w_1(X)r_1(Y)w_1(Y)$$

$$T_2 : r_2(Y)w_2(Y)r_2(Z)w_2(Z)$$

where $r_i(V)$ denotes a *read* operation by transaction T_i on a variable V and $w_i(V)$ denotes a *write* operation by transaction T_i on a variable V. The total number of conflict serializable schedules that can be formed by T_1 and T_2 is _______. **[2017]**

FILES

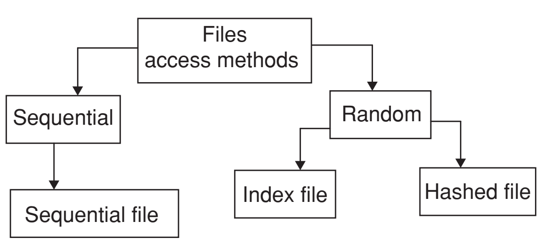
Databases are stored on magnetic disks as files of records. Computer storage media form a storage hierarchy that includes two main categories.

Primary storage This category includes storage media that can be operated on, directly by CPU, such as the computer main memory and cache memory. Primary storage provides fast access but is of limited storage capacity.

Secondary storage This category includes magnetic disks, optical disks, and tapes. These devices usually have a larger capacity, less cost, and slower access to data. Data in secondary storage cannot be processed directly by the CPU, it must be copied into primary storage.

File Structure

Taxonomy of file structure



Sequential file A sequential file is one in which records can only be accessed sequentially, one after another from beginning to end. Records are stored contiguously on the storage device.

Index files These files are used to access a record in the file. The entire index file is loaded into main memory data and indexes are stored in the same file. The term 'index file' is used as a synonym for the term 'database file'. The index file contains parameters that specify the name and location of file used to store DB.

Indexing Indexing mechanism is used to speed up access to desired data. An index file consists of records (called *index entries*) of the form.

Search-key	Pointer

Index files are typically much smaller than the original file.

Ordered indices In ordered index, index entries are stored, sorted on the search-key value.
Example: Author catalogue in library.

MEMORY HIERARCHIES

At the primary storage level, the memory hierarchy includes cache memory which is a static RAM.

The next level of primary storage is DRAM (dynamic RAM) which provides the main work area for the CPU for keeping programs and data and is called the *main memory*.

At the secondary storage level, the hierarchy includes magnetic disks, as well as mass storage in the form of CD-ROM (compact disk read-only memory) and tapes. Programs reside in DRAM and large permanent databases reside on secondary storage.

Another form of memory, *flash memory*, is non-volatile. Flash memories are high-density, high-performance memories using EEPROM (electrically erasable programmable read-only

memory) technology. The advantage of flash memory is the fast access speed, the disadvantage is that an entire block must be erased and written over at a time. Finally, magnetic tapes are used for archiving and backup storage of data.

Description of Disk Devices

Magnetic disks are used for storing large amounts of data. The capacity of a disk is the number of bytes it can store. A disk is single sided if it stores information on only one of its surfaces and double sided if both surfaces are used. To increase storage capacity, disks are assembled into a disk pack, which may include many disks and hence many surfaces. Information is stored on a disk surface in concentric circles with small width, each having a distinct diameter. Each circle is called a *track*. For disk packs, the tracks with the same diameter on the various surfaces are called a *cylinder* because of the shape they would form if connected in space.

A track usually contains a large amount of information; it is divided into smaller blocks (or) sectors. The division of track into equal-sized disk blocks (or pages) is set by the operating system during disk formatting.

Blocks are separated by fixed-size inter-block gaps, which include specially coded control information written during disk initialization. This information is used to determine which block on the track follows each inter block gap. Transfer of data between main memory and disk takes place in units of disk blocks. The hardware address of a block is the combination of a cylinder number, track number and block number is supplied to the disk I/O hardware.

The actual hardware mechanism that reads or writes a block is the disk read/write head, which is part of a system called a *disk drive*. A disk is mounted in the disk drive, which includes a motor that rotates the disk. To transfer a disk block, given its address, the disk controller must first mechanically position the read/write head on the correct track. The time required to do this is called the *seek time*. There is another delay called *rotational delay* or *latency*; the beginning of the desired block rotates into position under the read/write head. It depends on the RPM of the disk. Finally, some additional time is needed to transfer the data, which is called *block-transfer time*. Hence, the total time needed to locate and transfer an arbitrary block, given its address is the sum of the seek time, rotational delay and block transfer time. The seek time and rotational delay are usually much larger than the block transfer time.

File Records

Data is usually stored in the form of *records*. Each record consists of a collection of related data values or items where each value is of one or more bytes and corresponds to a particular field of the record. Records describe entities and their attributes.

Record type A collection of field names and their corresponding data types constitutes a record type (or) record format.

A file is a sequence of records. If every record in the file has exactly the same size (in bytes), the file is said to be made up of fixed-length records. If different records in the file have different sizes, the file is said to be made up of variable-length records.

Spanned Versus Unspanned Records

The records of a file must be allocated to disk blocks because a block is the unit of data transfer between disk and memory. When the block size is larger than the record size, each block will contain numerous records, although some files may have unusually large records that cannot fit in one block.

Suppose that the block size is B bytes. For a file of fixed-length records of size R bytes, with $B \geq R$, we can fit

$$\boxed{bfr = \lfloor B/R \rfloor \text{ records per block}}$$

The value *bfr* is called the *blocking factor* for the file. Some times R may not divide B exactly, so we have some unused space in each block equal to $B - (bfr * R)$ bytes. To utilize this unused space, we can store part of a record on one block and the rest on another. A pointer at the end of the first block points to the block containing the remainder of the record in case it is not the next consecutive block on disk. This organization is called *spanned*, because records can span more than one block. Whenever a record is larger than a block, we must use a spanned organization. If records are not allowed to cross block boundaries, the organization is called *unspanned*. This is used with fixed-length records having $B > R$, because it makes each record start at a known location in the block. For variable-length records, either a spanned or an unspanned organization can be used.

For variable-length records using spanned organization, each block may store a different number of records. In this case, the blocking factor *bfr* represents the average number of records per block for the file. We can use *bfr* to calculate the number of blocks '*b*' needed for a file of '*r*' records.

$b = \lceil (r/bfr) \rceil$ blocks

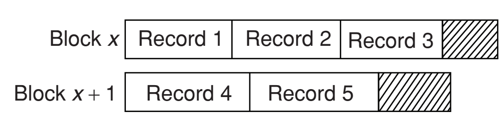


Figure 1 Unspanned records

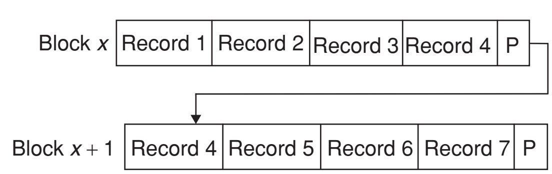

Figure 2 Spanned

There are several standard techniques for allocating the blocks of a file on disk. In contiguous allocation, the file blocks are allocated to consecutive disk blocks. In linked

allocation, each file block contains a pointer to the next file block. A combination of the two allocates clusters of consecutive disk blocks, and the clusters are linked. Clusters are sometimes called file *segments* (or) *extents*. Another possibility is to use indexed allocation, where one or more index blocks contain pointers to the actual file blocks.

Sorted Files (Ordered Records)

We can physically order the records of a file on disk based on the values of the one of their fields called the *ordering field*. This leads to an ordered or sequential file. If the ordering field is also a key field of the file, a field guaranteed to have a unique value in each record, then the field is called the *ordering key for the file*.

Advantages

1. Reading the records in order of the ordering key values becomes extremely efficient, because no sorting is required.
2. Finding the next record from the current one in order of the ordering key usually requires no additional block access, because the next record is in the same block as the current one.
3. Using a search condition based on the value of an ordering key field results in faster access when the binary search technique is used. This constitutes an improvement over linear searches, although it is not often used for disk files.

A binary search for disk files can be done on the blocks rather than on the records. Suppose that a file has 'b' blocks numbered 1, 2 ,…, b, the records are ordered by ascending value of their ordering key field and we are searching for a record whose ordering key field value is K. Assuming that disk addresses of the file blocks are available in the file header, the binary search usually accesses $\log_2^{(b)}$ blocks, whether the record is found (or) not, an improvement over linear searches, where, on the average, (b/2) blocks are accessed when the record is found and 'b' blocks are accessed when the record is not found.

Type of Organization	Access Method	Average Time to Access a Specific Record
Heap (unordered)	Sequential scan (linear search)	$b/2$
Ordered	Ordered scan	$b/2$
Ordered	Binary search	$\log_2 b$

Ordered files are rarely used in database applications unless an additional access path, called a *primary index*, is used; this results in an indexed sequential file. This further improves the random access time on the ordering key field.

Hashing Techniques

The other type of primary file organization is based on hashing, which provides very fast access to records on certain search conditions. This organization is usually called a *hash file*.

The search condition must be an equality condition on a single field, called the *hash field* of the file. If the hash is also a key field of the file, in which case it is called the *hash key*.

The idea behind hashing is to provide a function 'h', called a hash function or randomizing function, which is applied to the hash field value of a record and yields the address of the disk block in which the record is stored. We need only a single-block access to retrieve that record.

Example:

	NAME	RNO	CLASS	GRADE
0				
1				
2				
3				
.			.	
.			.	
.			.	
$m-2$				
$m-1$				

Internal Hashing

For internal files, hashing is implemented as a hash table through the use of an array of records. Suppose that the array index range is from 0 to M – 1, then we have M slots whose addresses corresponds to the array indexes. We choose a hash function that transforms the hash field value into an integer between 0 and M – 1. One common hash function is the $h(K) = K \bmod M$ function, which returns the remainder of an integer hash field value K after division by M; this value is then used for the record address.

Non-integer hash field values can be transformed into integers before the mod function is applied. For character strings, the numeric (ASCII) codes associated with characters can be used in the transformation.

A collision occurs when the hash field value of a record that is being inserted hashes to an address that already contains a different record. In this situation, we must insert the new record in some other position, since its hash address is occupied. The process of finding another position is called *collision resolution*. There are different methods for collision resolution as follows:

Open addressing Proceeding from the occupied position specified by the hash address, the program checks the subsequent positions in order until an unused (empty) position is found.

Chaining For this method, various overflow locations are kept, usually by extending the array with a number of overflow positions. In addition, a pointer field is added to each record location. A collision is resolved by placing the new record in an unused overflow location and setting the pointer of the occupied hash address location to the address of that overflow location. A linked list of overflow records for each hash address is thus maintained.

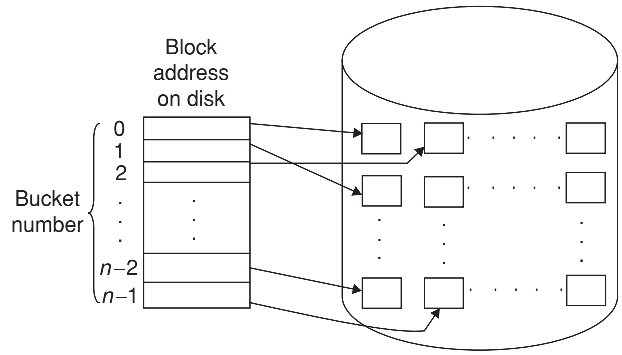
Multiple hashing The program applies a second hash function if the first results in a collision. If another collision results, the program uses open addressing or applies a third hash function and then uses open addressing if necessary.

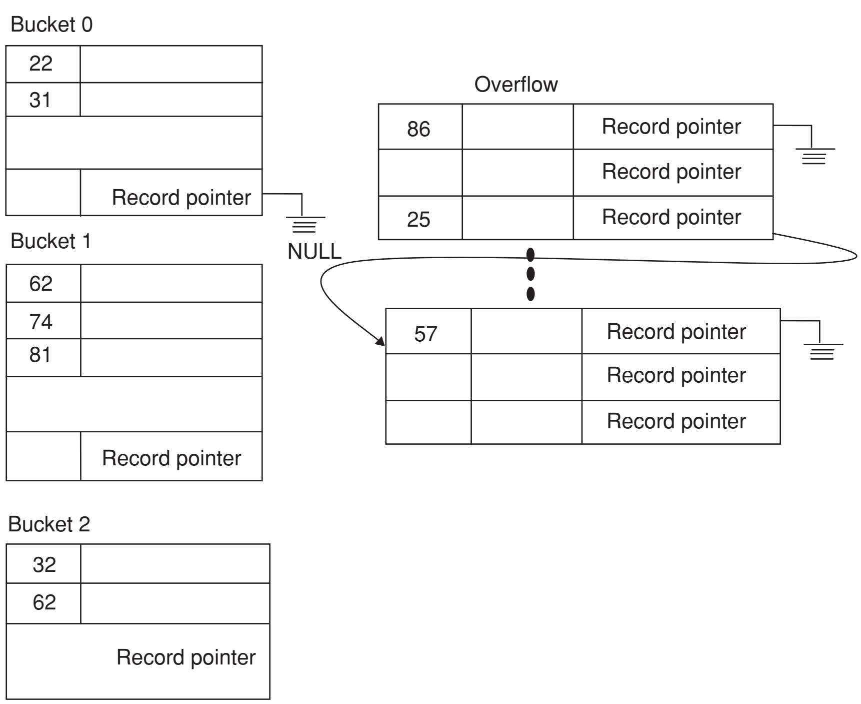
If we expect to have '*r*' records to store in the table, we should choose *M* locations for the address space such that (r/M) is between 0.7 and 0.9. It may also be useful to choose a prime number for *M*, since it has been demonstrated that this distributes the hash addresses better over the address space when the 'mod' hashing function is used. Other hash functions may require *M* to be a power of 2.

External Hashing

Hashing for disk files is called *external hashing*. To suit the characteristics of disk storage, the target address space is made of buckets, each of which holds multiple records. A bucket is either one disk block or a cluster of contiguous blocks. The hashing function maps a key into a relative bucket number, rather than assigning an absolute block address to the bucket. A table maintained in the file header converts the bucket number into the corresponding disk block address.

The collision problem is less severe with buckets, because as many records as will fit in a bucket can hash to the same bucket without causing problems. If the capacity of bucket exceeds, we can use a variation of chaining in which a pointer is maintained in each bucket to a linked list of overflow records for the bucket. The pointers in the linked list should be record pointers, which include both a block address and a relative record position within the block.





The hash function is $h(k) = k \bmod 10$ and the hashing scheme described above is called *static hashing* because a fixed number of buckets *M* is allocated. It can be a drawback for dynamic files. Suppose that we allocate *M* buckets for the address space and let '*m*' be the maximum number of records that can fit in one bucket, then at most ($m * M$) records will fit in the allocated space. If the number of records turns out to be substantially fewer than ($m * M$), we are left with a lot of unused space.

If the number of records increases to substantially more than ($m * M$), numerous collisions will result and retrieval will be slowed down because of the long lists of overflow

records. In either case, we may have to change the number of blocks M allocated and then use a new hashing function (based on the new value of M) to redistribute the records. These organizations can be quite time consuming for large files. Newer dynamic file organizations based on hashing allows the number of buckets to vary dynamically with only localized reorganization.

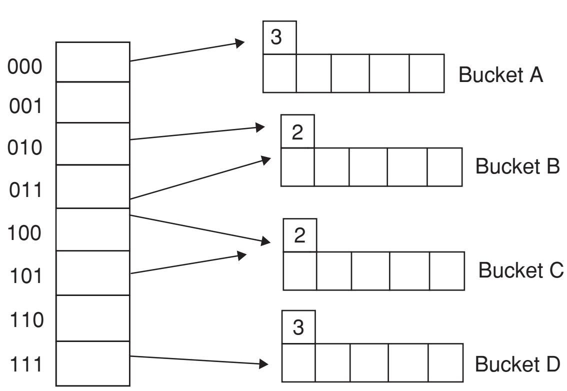
Hashing Techniques with Dynamic File Expansion

The disadvantage of static hashing is that the hash address space is fixed. Hence, it is difficult to expand or shrink the file dynamically. The first scheme is extendible hashing, It stores an access structure in addition to the file hence it is similar to indexing. The main difference is that the access structure is based on the values that result after application of the hash function to the search field. In indexing, the access structure based on the values of the search field itself. The second technique, called *linear hashing*, does not require additional access structure.

These hashing schemes take advantage of the fact that the result of applying a hashing function is a non-negative integer and hence can be represented as a binary number. The access structure is built on the binary representation of the hashing function result, which is a string of bits. We call this the *hash value of a record*. Records are distributed among buckets based on the values of the leading bits in their hash values.

Extendible Hashing

In extendible hashing, a type of directory, an array of 2^d bucket addresses is maintained, where d is called the *global depth of the directory*. The integer value corresponding to the first (high-order) d bits of a hash value is used as an index to the array to determine a directory entry, and the address in that determines the bucket in which the corresponding records are stored. Several directory locations with the same first d' bits for their hash values may contain the same bucket address if all the records that hash to these locations fit in a single bucket. A local depth d' is stored with each bucket specifies the number of bits on which the bucket contents are based.



The value of d can be increased and decreased by one at a time, thus doubling or halving the number of entries in the directory array. Doubling is needed if a bucket, whose local depth d' is equal to the global depth d, overflows. Halving occurs if $d > d'$ for all the buckets after some locations occur. Most record retrievals require two block accesses: one to the directory and the other to the bucket.

The main advantage of extendible hashing is the performance of the file does not degrade as the file grows, as opposed to static external hashing where collisions increases and the corresponding chaining causes additional accesses. No space is allowed in extendible hashing for future growth, but additional buckets can be allocated dynamically as needed. The space overhead for the directory table is negligible.

Another advantage is that splitting causes minor reorganization in most cases, since only the records in one bucket are redistributed to the two new buckets. The only time a reorganization is more expensive is when the directory has to be doubled (or) halved.

A disadvantage is that the directory must be searched before accessing the buckets themselves, resulting in two block accesses instead of one in static hashing.

Indexing

Indexes are auxiliary access structures, which are used to speed up the retrieval of records in response to certain search conditions. The index structure typically provides secondary access paths, which provide alternative ways of accessing the records without affecting the physical placement of records on disk. They enable efficient access to records based on the indexing fields that are used to construct the index.

Any field of the file can be used to create an index and multiple indexes on different fields can be constructed on the same file. To find a record or records in the file based on a certain selection criterion on an indexing field, one has to initially access the index, which points to one or more blocks in the file where the required records are located. The most prevalent types of indexes are based on ordered files (single-level indexes) and tree data structures (multilevel indexes, B^+ trees).

Dense Index files: Index record appears for every search-key value in the file.

A-110	Downtown	300
A-215	Mianus	400
A102	Perryridge	800

Figure 3 Dense index file.

Sparse index files These files contain index records for only some search-key values. Applicable when records are sequentially ordered on search key.

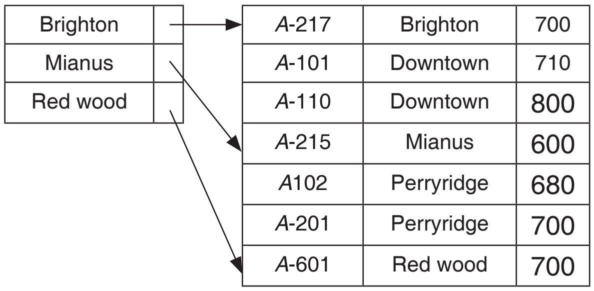

Figure 4 Sparse index file.

Compared to dense index, sparse index takes less space and less maintenance over head for insertions and deletions. It is slower than dense index for locating records.

Index Update

Record deletion If delete key was the only record in the file with its particular search-key value, the search key is deleted from the index also.

In dense index, delete the search key.

In spare index, if deleted key value exists in the index, the value is replaced by next search-key value in the file. If the next search-key value already has an index entry, the entry is deleted instead of being replaced.

Record insertion In dense index, if the search-key value doesn't appear in the index insert it.

If index stores an entry for each block of the file, no change needs to be made to the index unless a new block is created. If a new block is created, the first search-key value appearing in the new block is inserted into the index.

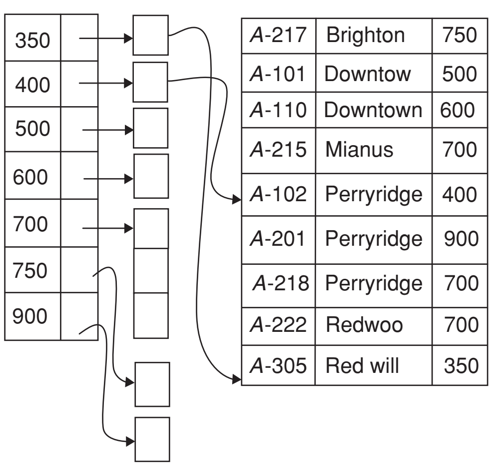

Figure 5 Secondary index.

Secondary index example:

1. Index record points to a bucket that contains pointers to all the actual records with that particular search – key value
2. secondary index have to be dense

Single-level Ordered Indexes

A file with a given record structure consisting of several fields (or attributes), an index access structure is usually defined on a single field of a file is called an *indexing field* or *indexing attribute*. The index typically stores each value of the index field along with a list of pointers to all disk blocks that contain records with that field value. The values in the index are ordered so that we can do a binary search on the index.

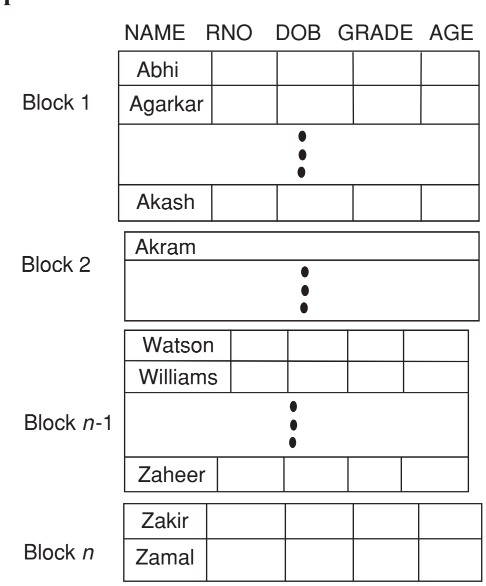
The index file is much smaller than the data file, so searching the index using a binary search is reasonably efficient. Multilevel indexing does away the need for a binary search at the expense of creating indexes to the index itself.

Types of Ordered Indexes

1. Primary index
2. Clustering index
3. Secondary index

Primary index A primary index is an ordered file whose records are of fixed length with two fields. The first field is of the same data type as the ordering key field called the *primary key of the data file*, and the second field is a pointer to a disk block (block address). There is one index entry (index record) in the index file for each block in the data file. Each index entry has the value of the primary key field for the record in a block and a pointer to that block as its two field values. The two field values of index entry i is $<k(i), p(i)>$.

Example:



To create a primary index on the ordered file shown in the above figure, we use the NAME field as primary key, because that the ordering key field on the file (assuming that each value of NAME is unique). Each entry in the index has a NAME value and a pointer. Some sample index entries are as follows:

$< k(1) = (\text{Abhi}), p(1) = \text{address of block } 1 >$
$< k(2) = (\text{Akram}), p(2) = \text{address of block } 2 >$
$< k(3) = (\text{Brat}), p(3) = \text{address of block } 3 >$

The below figure illustrates this primary index. The total number of entries in the index is the same as the number of disk blocks in the ordered data file. The first record in each block of the data file is called the *anchor record of the block (or) block anchor*.

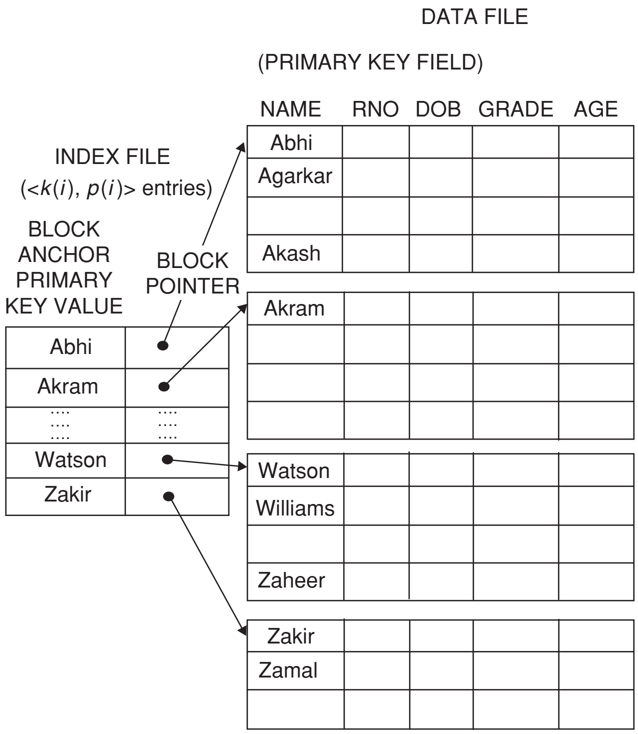


Figure 6 Primary index on the ordering key field of the file.

Indexes can also be characterized as dense or sparse. A dense index has an index entry for every search-key value (every record) in the data file. A sparse (non-dense) index has index entries only for some of the search values. A primary index is non-dense (sparse) index, since it includes an entry for each disk block of the data file and the keys of its anchor record rather than for every search value.

The index file for primary index needs fewer blocks than does the data file, for two reasons as follows:

1. There are fewer index entries than there are records in the data file.
2. Each index entry is typically smaller in size than a data record because it has only two fields. So more index entries than data records can fit in one block.

A binary search on the index file requires fewer block accesses than a binary search on the data file. The binary search for an ordered data file required $\log_2{}^b$ block accesses. But if the primary index file contains b_i blocks, then to locate a record with a search-key value requires a binary search of that index and access to the block containing that record, a total of $\log_2{}^b{}_i + 1$ accesses.

A record whose primary key value is k lies in the block whose address is $p(i)$, where $k(i) \le k \le k(i + 1)$. The ith block in the data file contains all such records because of the physical ordering of the file records on the primary key field. To retrieve a record, given the value k of its primary key field, we do a binary search on the index file to find the appropriate index entry i, and then retrieve the data file block whose address is $p(i)$.

The following example illustrates the saving in block accesses that is attainable when a primary index is used to search for a record.

Example: Suppose that we have an ordered file with r = 24,000 records stored on a disk with block size B = 512 bytes. File records are of fixed size and are unspanned, with record length R = 120 bytes.

The blocking factor for the file would be $bfr = \lfloor B/R \rfloor$

$$= \left\lfloor \frac{512}{120} \right\rfloor = \lfloor 4.26 \rfloor = 4 \text{ records per block}$$

The number of blocks needed for the file is

$$b = \left\lceil \left(\frac{r}{bfr} \right) \right\rceil = \left\lceil \frac{24,000}{42} \right\rceil = 6000 \text{ blocks}$$

A binary search on the data file would need

$\lceil \log_2{}^b = \log_2{}^{6000} \rceil = 13$ block accesses

Example: For the above data, suppose that the ordering key field of the file is V = 7 bytes long, a block pointer, P = 5 bytes long, and we have constructed a primary index for the file.

The size of each index entry is $R_i = (7 + 5) = 12$ bytes, so the blocking factor for the index is $bfr_i = \lfloor (B/R_i) \rfloor$

$\lfloor 512/12 \rfloor = \lfloor 42.66 \rfloor = 42$ entries per block.

The total number of index entries r_i is equal to number of blocks in the data file, which is 6000. The number of index blocks is hence

$b_i = \lceil (r_i/bfr_i) \rceil = \lceil 6000/42 \rceil = 142$ blocks

To perform a binary search on the index file would need $\lceil \log_2 b_i \rceil = \lceil \log_2 142 \rceil = 8$ block accesses. To search for a record using the index, we need one additional block access to the data file for a total of '9' block accesses.

Disadvantage: A major problem with a primary index is insertion and deletion of records. If we attempt to insert a record in its correct position in the data file, we have to not only move records to make space for the new record but also change some index entries.

Clustering Index If records of a file are physically ordered on a non-key field, which does not have a distinct value for each record, that field is called the *clustering field*. We can create a different type of index called *clustering index* to

speed up the retrieval of records that have the same value for the clustering field.

A clustering index is also an ordered file with two fields, the first field is of the same type as the clustering field of the data file, and the second field is a block pointer.

There is one entry in the clustering index for each distinct value of the clustering field, containing the value and a pointer to the first block in the data file that has a record with that value for its clustering field.

The record insertion and deletion still cause problems, because the data records are physically ordered. To alleviate the problem of insertion, reserve a whole block (or a cluster of contiguous blocks) for each value of the clustering field, all records with that value are placed in the block (or block cluster). A clustering index is an example of a non-dense index, because it has an entry for every distinct value of the indexing field which is a non-key.

Secondary Index A secondary index provides a secondary means of accessing a file for which some primary access already exists. The secondary index may be on a field which is a candidate key and has a unique value in every record, or a non-key with duplicate values. The index is an ordered file with two fields. The second field is either a block pointer or a record pointer. There can be many secondary indexes for the same file.

First consider a secondary index access structure on a key field that has a distinct value for every record such a field is some times called a *secondary key*.

The records of the data file are not physically ordered by values of the secondary key field, we cannot use block anchors. That is why an index entry is created for each record in the data file, rather than for each block, as in the case of a primary index.

B^- Trees

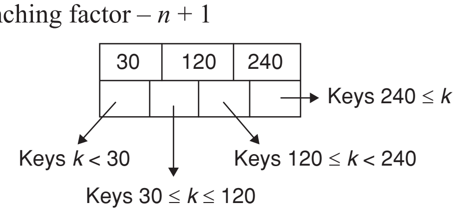
1. A commonly used index structure
2. Non-sequential, 'balanced'
3. Adapts well to insertions and deletions
4. Consists of blocks holding at most n keys and $n + 1$ pointers.
5. We consider a variation actually called a B^+ *tree*

B^+ Trees

B^+ trees are a variant of B^- trees. In B^+ trees data stored only in leaves, leaves form a sorted linked list.

Parameter – n

Branching factor – $n + 1$

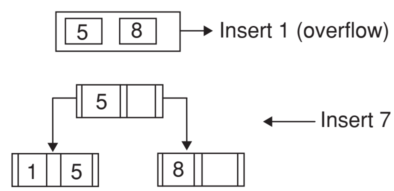


Each node (except root) has at least $n/2$ keys. B^-tree stands for balanced tree. All the paths through a B^-tree from root to different leaf nodes are of the same length (balanced path length). All leaf nodes are at the same depth level.

This ensures that number of disk accesses required for all the searches are same. The lesser the depth (level) of an index tree, the faster the search.

Insertion into B^+ tree

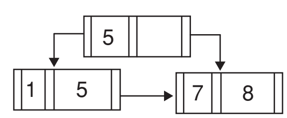
Given nodes 8 5 1 7 3 12 Initially start with root node (has no children)



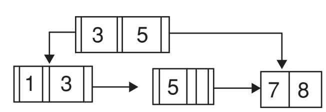
Overflow in Leaf Node

Split the leaf node First, j = ceiling $((p_{leaf} + 1)/2)$ entries are kept in the original node and the remaining moved to the new leaf.

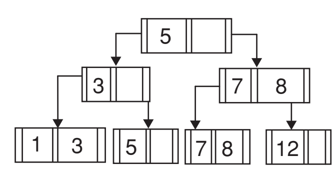
1. Create a new internal node, and jth index value is replicated in the parent internal node.
2. A pointer is added to the newly formed leaf node.



Insert 3 → overflow



Insert 12 (overflow, split propagates, new level)



Overflow in Internal Node

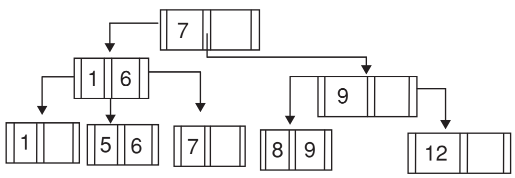
Split the internal node, the entries up to P_j where j = floor $((p + 1)/2)$ are kept in the original node and remaining moved to the new internal node

1. Create a new internal node and the jth index value is moved to the parent internal node (without replication)
2. Pointers are added to the newly formed nodes.

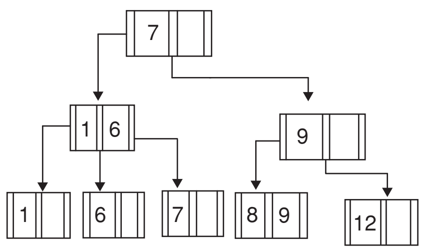
3. B^+ tree ensures some space always left in nodes for new entries. Also makes sure all nodes are at least half full.

Deletion in B^+ Trees

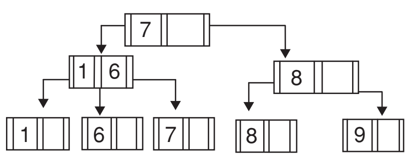
Delete 5,12,9 from the below B^+ tree:



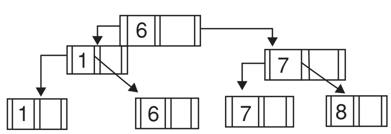
Delete 5:



Delete 12:
Under flow has occurred, so redistribute.



Delete 9: Underflow (merge with left) redistribute.



Advantages

1. B^- *Trees and* B^+ *trees*: B^- tree is a data structure used for external memory.
2. B^- trees are better than binary search trees if data is stored in external memory.
3. Each node in a tree should correspond to a block of data.
4. Each node can store many data items and has many successors.
5. The B^- tree has fewer levels but search for an item takes more comparisons at each level.
6. If a B^- tree has order 'd', then each node (except root) has at least d/2 children, then the depth of the tree is at most $\log_{d/2}$ (size) + 1.
7. In the worst case, we need $(d - 1)$ comparisons in each node (using linear search)
8. Fewer disk accesses are required compared to binary Tree.
9. The usual data structure for an index is the B^+ tree.
10. Every modern DBMS contains some variant of B^- trees in addition with other index structures depending on the application.
11. B^- trees and B^+ trees are one and the same. They differ from B^- trees in having all data in the leaf blocks.
12. Compared to binary trees, B^- trees will have higher branching factor.
13. Binary trees can degenerate to a linear list, B^- trees are balanced, so this is not possible.
14. In B^+ tree, the values in inner nodes are repeated in the leaf nodes.
15. The height of the tree might decrease, because the data pointer is needed only in the leaf nodes, we can also get a sorted sequence.
16. In B^- trees, all leaves have the same distance from root hence B^- trees are balanced. This ensures that the chain of links followed to access a leaf node is never too long.
17. The time complexity of search operation in B^- tree (tree height) is $O(\log n)$, where 'n' is the number of entries.
18. Advantage of B^+ tree automatically reorganizes itself with small and local changes while doing insertions and deletions, reorganization of entire file is not required to maintain performance.
19. Disadvantage of B^+ tree, extra Insertion and deletion overhead, space overhead.
20. B^+ trees can be used as dynamic multilevel Indexes.

Exercises

Practice Problems I

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider the following specifications of a disk. Block size of a disk is 512 bytes, inter-block gap size is 128 bytes Number of blocks per track is 20 and number of tracks per surface is 400.

(i) What is the capacity of disk including Inter block gap?

(A) 124000 (B) 1260000
(C) 5120000 (D) 512000

(ii) What is the capacity of disk excluding Inter block gap?

(A) 25400 (B) 25600
(C) 25800 (D) 25900

2. Consider the following specifications of a disk. Block size of disk is 512 bytes, 2000 tracks per surface, 50 sectors per track and 5 double sided platters.

(i) What is the capacity of track in bytes?
(A) 4096000 (B) 4086000
(C) 4076000 (D) 4066000

(ii) What is the capacity of surface in bytes?
(A) 25600000 (B) 512000
(C) 5120000 (D) 51200000

(iii) What is the capacity of disk in bytes?
(A) 512*10^4 (B) 512*10^5
(C) 512*10^6 (D) 512*10^7

(iv) How many cylinders does it have?
(A) 512 (B) 1000
(C) 2000 (D) 2048

(v) Identify the In valid disk block size from below:
(A) 2048 (B) 51200
(C) 4098 (D) 4096

3. What is the order of internal node of B^+ tree suppose that a child pointer takes 6 bytes, the search field value takes 14 bytes and the block size is 512 bytes?
(A) 23 (B) 24
(C) 25 (D) 26

4. The order of a leaf node in a B^+ tree is the maximum number of (value, data, record pointer) pairs it can hold. Given that block size is 1 k bytes (1024 bytes), data record pointer is 7 bytes long, the value field is '9' bytes long and block pointer is 6 bytes.
(A) 63 (B) 64
(C) 65 (D) 66

5. The following key values are inserted into a B^+ tree in which order of the internal nodes is 3, and that of the leaf nodes is 2, in the sequence given below. The order of internal nodes is the maximum number of tree pointers in each node, and the order of leaf nodes is the maximum number of data items that can be stored in it. The B^+ tree is initially empty. 10, 3, 6, 8, 4, 2, 1. What is the maximum number of times leaf nodes would get split up as a result of these insertions?
(A) 3 (B) 4
(C) 5 (D) 6

6. For the same key values given in the above question, suppose the key values are inserted into a B^- tree in which order of the internal nodes is 3 and that of leaf nodes is 2. The order of internal nodes is the maximum number of tree pointers in each node and the order of leaf nodes is the maximum number of data items that can be stored in it. The B^- tree is initially empty. What is the maximum number of times leaf nodes would get split up as a result of these insertions?
(A) 1 (B) 2
(C) 3 (D) 4

7. Suppose that we have an ordered file with 45,000 records stored on a disk with block size 2048 bytes. File records are of fixed size and are unspanned with record length 120 bytes.

(i) What is the blocking factor?
(A) 16 (B) 17
(C) 18 (D) 19

(ii) What is the number of blocks needed for the file?
(A) 2642 (B) 2644
(C) 2646 (D) 2648

(iii) How many block accesses are required to search for a particular data file using binary search?
(A) 10 (B) 11
(C) 12 (D) 13

8. Suppose that the ordering key field of the file is 12 bytes long, a block pointer is 8 bytes long, and we have constructed a primary index for the file. Consider the file specifications given in the above questions.

(i) What is the size of each index entry?
(A) 16 (B) 18
(C) 20 (D) 22

(ii) What is the blocking factor for the index?
(A) 101 (B) 102
(C) 103 (D) 104

(iii) What is the total number of index entries?
(A) 2642 (B) 2644
(C) 2646 (D) 2648

(iv) What is the number of index blocks?
(A) 22 (B) 24
(C) 26 (D) 28

(v) How many block accesses are required, if binary search is used?
(A) 3 (B) 4
(C) 5 (D) 6

9. For the file specifications given in Q. No. 7, if we construct secondary index on a non-ordering key field of the file that is 12 bytes long, a block-pointer of size 8 bytes, each index entry is 20 bytes long and the blocking factor is 102 entries per block.

(i) What is the total number of index blocks?
(A) 422 (B) 424
(C) 442 (D) 444

(ii) How many block accesses are required to access the secondary index using binary search?
(A) 6 (B) 7
(C) 8 (D) 9

10. For the file specifications given in Q. No. 8, if we construct a multilevel index, number of 1st-level blocks are 442, blocking factor is 102, each index entry is 20 bytes long.

(i) What is the number of 2nd-level blocks?
(A) 4 (B) 5
(C) 6 (D) 7

(ii) What is the number of 3rd-level blocks?
(A) 0 (B) 1
(C) 2 (D) 3

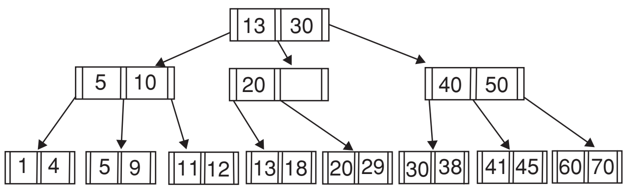
11. Construct a B^+ tree for (1,4,7,10,17,21,31) with $n = 4$, which nodes will appear two times in a final B^+ tree?

(A) 17,7,20 (B) 17,7,20,25
(C) 17,20,25 (D) 7,17.25

12. Suppose the hash function is $h(x) = x\bmod 8$ and each bucket can hold at most two records. The extendable hash structure after inserting 1, 4, 5 ,7, 8, 2, 20, what is the local depth of '4'?

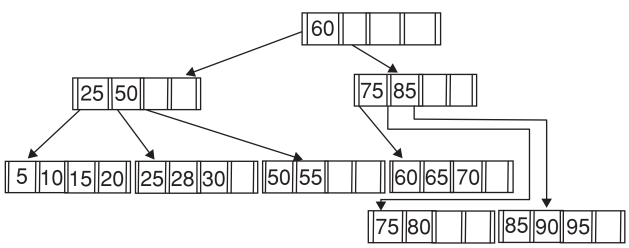
(A) 0 (B) 1
(C) 2 (D) 3

13. Consider the given B^+ tree, insert 19 into the tree, what would be the new element in level 2?



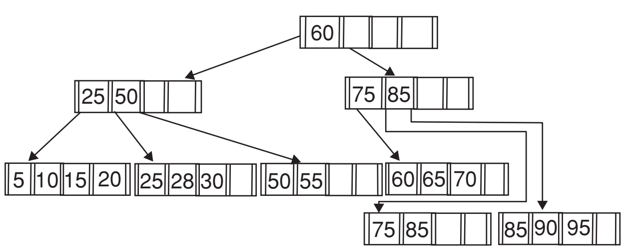
(A) 13 (B) 18
(C) 20 (D) 29

14. Consider the given B^+ tree, delete 70 and 25 from the tree, what are the elements present in level 2? (∴ root is at level 1)



(A) 25, 50, 75 (B) 25, 50,75, 85
(C) 28, 50, 75, 85 (D) 28, 50, 65, 75

15. Delete 60 from the above given tree (Q. No. 14). After deletion, what is the total number of nodes present in the tree?



(A) 5 (B) 6
(C) 7 (D) 8

16. What will be the number of index records/block?

(A) 68 (B) 65
(C) 69 (D) None

17. What will be the number of index blocks?

(A) 442 (B) 440
(C) 400 (D) None

18. Consider the following:

Block size = 1025 bytes

Record length in data file = 100 bytes

Total number of records = 30000

Search key = 9 bytes

Pointer = 6 bytes

What is the number of index blocks?

(A) 44 (B) 45
(C) 46 (D) None

19. Which of the following is maximum search time $t_{\max}$ in B^- trees?

(A) $t_{\max} = a\log_2\left(\frac{N}{2}\right)\left[\frac{a+d}{\log_2 m} + \frac{bm}{\log_2 m} + c\right]$

(B) $t_{\max} = a\log_2\left(\frac{N}{2}\right)\left[\frac{a+d}{\log_2 m} + \frac{bm}{\log_2 m} + c\right]$

(C) $t_{\max} = a\log_2 N\left[\frac{a+d}{\log_2 m} + \frac{bm}{\log_2 m} + c\right]$

(D) $t_{\max} = a\log_2(N)\left[\frac{a}{\log_2 m} + \frac{bm}{\log_2 m} + c\right]$

20. Consider a B^+ tree. A child pointer takes 3 bytes, the search field value takes 7 bytes, and the block size is 256 bytes. What is the order of the internal node?

(A) 63 (B) 64
(C) 65 (D) 66

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Which of the following is true?
   (A) Every conflict serializable is view serializable
   (B) Every view serializable is conflict serializable
   (C) Both A and B
   (D) A schedule can be either only conflict serializable or only view-serializable.

2. Which one is the 2-phase locking rule?
   (A) Two transactions cannot have conflicting locks
   (B) No unlock operation can precede a lock operation in the same transaction.
   (C) No data is/are affected until all locks are obtained and until the transaction is in its locked point.
   (D) All of the above

3. If Transaction T_i has obtained an exclusive mode lock on item Q, then
   (A) T_i can read Q
   (B) T_i can write Q
   (C) T_i can read and write
   (D) Neither read nor write

4. Phantom phenomenon is
   (A) A transaction retrieves a collection of objects but sees same result.
   (B) A transaction retrieves a collection of objects but sees different results.
   (C) Transaction T_1 waits for T_2 and T_2 waits for T_1
   (D) This problem arises when the transaction has not locked all the objects.

5. We can avoid the starvation of transactions by granting locks by following manner:

   When a transaction T_i requests a lock on a data item Q in a particular mode M, the concurrency control manager grants the lock provided that
   (A) There is no other transaction holding a lock on Q in a mode that conflicts with M.
   (B) There is no other transaction that is waiting for a lock on Q,
   (C) (A) and (B)
   (D) None

6. Which one is correct?
   (A) Upgrading can take place only in shrinking phase
   (B) Upgrading can take place only in growing phase.
   (C) Downgrading can take place only in growing phase
   (D) (A) and (C) both

7. A simple but widely used scheme automatically generates the appropriate lock and unlock instructions for a transaction, on the basis of read and write requests from the transaction:
   (A) When a transaction T_i issues a read (Q) operation, the system issues a lock $s(Q)$ instruction followed by the read instruction.
   (B) When T_i issues a write Q operation, the system checks to see whether T_i already holds a shared lock on Q. If it does, then the system issues an upgrade Q instruction followed by the write Q instruction, otherwise the system issues a lock -$X(Q)$ instruction, followed by the write Q instruction.
   (C) All locks obtained by a transaction are unlocked after that transaction commits or aborts.
   (D) All of the above

8. Which one is correct?
   (A) A lock manager can be implemented as a process that receives messages from transactions and sends messages in reply.
   (B) It uses linked list of records.
   (C) It uses hash table called lock table.
   (D) All of the above

Common data questions 9 and 10: Transaction T_1 has 5 instructions. Transaction T_2 has 3 instructions.

9. The number of non-serial transactions will be
   (A) 15 (B) 8
   (C) 2 (D) 56

10. The number of serial transaction schedules will be
    (A) 15 (B) 8
    (C) 2 (D) 56

11. In a heap file system, which of the following function finds 'average number of blocks to be read'?
    (A) $\frac{i}{n} = \frac{1}{2}(1+n) = \frac{n}{2}$
    (B) $\sum_{i=1}^{n} \frac{i}{n} = \frac{1}{2}(1+n) = \frac{n}{2}$
    (C) $\sum_{i=0}^{n-1} \frac{i}{n} = \frac{1}{2}(1+n) = \frac{n}{2}$
    (D) All of the above

12. What is the disadvantage in one directory per user?
    (A) Different applications can be divided into separate groups.
    (B) Different applications cannot be divided into separate groups
    (C) All files are in a single group
    (D) All of the above

13. What are the possible violations if an application program uses isolation-level 'Read uncommitted'?
    (A) Dirty read problem
    (B) Non-repeatable read problem
    (C) Phantom phenomenon
    (D) All of the above

14. The two-phase locking protocol
(A) ensures serializability
(B) issues locks in two phases
(C) unlocks in two phases
(D) All of the above

15. The point in the schedule where the transaction has obtained its final lock (the end of its growing phase) is called the
(A) block point (B) critical section
(C) growing point (D) lock point

16. Which of the following is not a problem of file management system?
(A) Data redundancy
(B) Lack of data independence
(C) Program dependence
(D) All of the above

17. Which of the following is/are true about master list of an index file?
(i) Is sorted in ascending order
(ii) A number is assigned to each record.
(A) Only (i) (B) Only (ii)
(C) Both (i) and (ii) (D) None of the above

18. To have a file, holding a list is necessary to
(i) Identify the records in the list
(ii) Identify the name, and type of the fields of each record.
(iii) Decide which fields will be used as sort of index keys.
(A) Only (i) and (ii)
(B) Only (i) and (iii)
(C) Only (ii) and (iii)
(D) All of the above

19. Two files may be joined into a third file, if the following is true:
(A) if they have row in common
(B) if they have a field in common
(C) Both (A) and (B)
(D) None

20. The minimum number of record movements required to merge four files w(with 10 records), x(with 20 records), y(with 15 records) and z(with 5 records) is:
(A) 50 (B) 40
(C) 30 (D) 35

Previous Years' Questions

1. A clustering index is defined on the fields which are of type **[2008]**
(A) non-key and ordering
(B) non-key and non-ordering
(C) key and ordering
(D) key and non-ordering

2. A B^- tree of order 4 is built from scratch by 10 successive insertions. What is the maximum number of node splitting operations that may take place? **[2008]**
(A) 3 (B) 4
(C) 5 (D) 6

3. Consider a file of 16384 records. Each record is 32 bytes long and its key field is of size 6 bytes. The file is ordered on a non-key field, and the file organization is unspanned. The file is stored in a file system with block size 1024 bytes, and the size of a block pointer is 10 bytes. If the secondary index is built on the key field of the file, and a multilevel index scheme is used to store the secondary index, the number of first-level and second-level blocks in the multilevel index are respectively **[2008]**
(A) 8 and 0 (B) 128 and 6
(C) 256 and 4 (D) 512 and 5

4. The following key values are inserted into a B^+ tree in which order of the internal node s is 3, and that of the leaf nodes is 2, in the sequence given below. The order of internal nodes is the maximum number of tree pointers in each node, and the order of leaf nodes is the maximum number of data items that can be stored in it. The B^+ tree is initially empty.

10, 3, 6, 8, 4, 2, 1

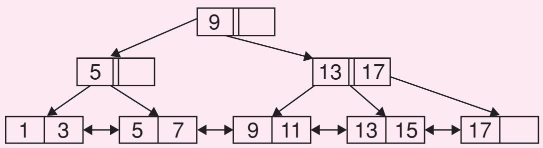
The maximum number of times leaf nodes would get split up as a result of these insertions is **[2009]**
(A) 2 (B) 3
(C) 4 (D) 5

5. Consider a B^+ tree in which the maximum number of keys in a node is 5. What is the minimum number of keys in any non-root node? **[2010]**
(A) 1 (B) 2
(C) 3 (D) 4

6. An index is clustered, if **[2013]**
(A) it is on a set of fields that form a candidate key.
(B) it is on a set of fields that include the primary key.
(C) the data records of the file are organized in the same order as the data entries of the index.
(D) the data records of the file are organized not in the same order as the data entries of the index.

7. A file is organized so that the ordering of data records is the same as or close to the ordering of data entries in some index. Then that index is called **[2015]**
(A) Dense (B) Sparse
(C) Clustered (D) Unclustered

8. With reference to the B+ tree index of order 1 shown below, the minimum number of nodes (including the Root node) that must be fetched in order to satisfy the following query: "Get all records with a search key greater than or equal to 7 and less than 15" is ________ **[2015]**



9. Consider a B^+ tree in which the search key is 12 bytes long, block size is 1024 bytes, record pointer is 10 bytes long and block pointer is 8 bytes long. The maximum number of keys that can be accommodated in each non-leaf node of the tree is ________. **[2015]**

10. B+ Trees are considered **BALANCED** because **[2016]**

(A) The lengths of the paths from the root to all leaf nodes are all equal.
(B) The lengths of the paths from the root to all leaf nodes differ from each other by at most 1.
(C) The number of children of any two non - leaf sibling nodes differ by at most 1.
(D) The number of records in any two leaf nodes differ by at most 1.

11. In a B+ tree, if the search-key value is 8 bytes long, the block size is 512 bytes and the block pointer size is 2 bytes, then the maximum order of the B+ tree is __________. **[2017]**

Test

Databases

Time: 60 min.

1. Which of the following are used in DBMS files?
(i) Data dictionary (ii) DML
(iii) Query language (iv) Transaction log
(A) (i) and (ii) (B) (ii) and (iii)
(C) (iii) and (iv) (D) (i) and (iv)

2. Which among the following is not a problem of file management system?
(A) Data redundancy
(B) Lack of data independence
(C) Program independence
(D) None of these

3. A transparent DBMS
(A) cannot hide sensitive information from users
(B) keeps its logical structure hidden from users
(C) keeps its physical structure hidden from users
(D) All of the above

4. If the field size is too small, for the longest piece of data to be entered,
(A) database program will be freezed
(B) field will automatically expand
(C) part of the data will be cut off
(D) All of the above

5. Which of the following functional dependencies are satisfied by the instance from the below relation?

A	B	C
1	7	3
1	9	5
1	11	5
5	3	3

(A) $AB \to C$ and $C \to B$
(B) $BC \to A$ and $B \to C$
(C) $BC \to A$ and $A \to C$
(D) $AC \to B$ and $B \to A$

6. Let E_1 and E_2 be two entities in an E/R diagram with single-valued attributes, R_1 and R_2 are two relationships between E_1 and E_2, R_1 is one to many R_2 is many-to-one. R_1 and R_2 do not have any attributes of their own. What is the minimum number of tables required to represent this situation in the relation model?
(A) 2 (B) 3
(C) 4 (D) 5

7. Which of the following is true about DBMS?
(i) Low-level DMLs are record-at-a time
(ii) High-level DMLs are set oriented or set-at-a time
(iii) Query in high-level DML specify which data to retrieve rather than how.
(iv) When used as standalone, DML is called 'host language'
(A) (i) only (B) (i) and (iii)
(C) (i), (ii) and (iii) (D) (iii) and (iv)

8. In which of the following, the structure of data files is stored?
(A) Metadata (B) Database catalog
(C) Database schema (D) Data model

9. A schedule is a collection of
(A) Data models (B) Transactions
(C) Schemas (D) Tables

10. Select from the following which matches the term 'Impedance mismatch problem':
(A) In compatibility of storage and data structure
(B) Mismatch in user authentication
(C) File structure mismatching
(D) None of these

11. Which of the following is not a/an integrity constraint?
(A) Entity integrity
(B) Candidate key constraint
(C) Business rules
(D) None of the above

12. Select from the following which is concerned with 'Query Optimizer':
(A) Extracts DML commands from an application program in a high-level language
(B) Parsing and analyzing interactive query
(C) Rearrangement and reordering of operations and elimination of redundancies
(D) Performance monitoring

13. Which of the following does not belong to database model?
(A) Relational Model (B) Distributed Model
(C) Hierarchical Model (D) Network Model

14. What is the correct sequence of database design process?
(i) Create conceptual schema
(ii) Data model mapping
(iii) Requirement collection and analysis
(iv) Physical design
(A) iii $\to$ i $\to$ ii $\to$ iv
(B) iii $\to$ ii $\to$ i $\to$ iv
(C) i $\to$ ii $\to$ iii $\to$ iv
(D) i $\to$ iii $\to$ ii $\to$ iv

15. Consider the following schema definitions
Employee {Name, SSN, Address, DNo}
Department {DName, DNumber, Manager, SSN}
Which among the following expressions represent the query $\Pi_{\text{name, address}}(\sigma_{\text{Dname = 'Res'} \wedge \text{DNumber = DNo}}$ (Department $\bowtie$ Employee)?

(A) Retrieve the name and address of employees who work for the project no 'Dno'
(B) Retrieve the name and address of all employees who control the 'Res' department.
(C) Retrieve the name and address of all employees who work for the 'Res' department.
(D) None of these

16. Select from the following which closely resembles the concept 'Degree of a relationship':
(A) Number of entities participating in a relation
(B) Number of entity types participating in a relation
(C) Number of strong entity types in a relation
(D) Number of weak entity types in a relation

17. Consider the following statements in a database:
(i) No primary key value can be NULL
(ii) A tuple in one relation which refers to another relation must refer to an existing tuple in that relation
(iii) The value of x determines the value of y in all states of a relation, where x and y are two attributes of the relation Which of the following combinations matches the given statements in order?
(A) Referential integrity, functional dependency, entity integrity.
(B) Functional dependency, entity integrity, referential integrity
(C) Entity integrity, functional dependency, referential integrity.
(D) Entity integrity, referential integrity, functional dependency

18. Consider the following relation schemas:

Works (emp_name, comp_name,salary)

Livesin (emp_name, street, city)

Location (comp_name, city)

Manager (manager_name)

What is returned by the following relational algebra expression

$\pi_{\text{emp\_name}}(\sigma_{\text{comp-name=Time} \wedge \text{Works.emp\_name=livesin.emp\_name}}$

(Works $\bowtie$ Livesin)
(A) Names of all employees who work for TIME
(B) Names of all employees of TIME who lives in the same city
(C) Names of people who live in the same city
(D) None of these

19. Consider the following SQL query:
Select distinct $a_1, a_2, \ldots, a_n$ from $r_1, r_2 \ldots r_m$ where P
This query is equivalent to one of the following relational algebra expression:

(A) $\pi_{a_1, a_2 \ldots a_n} \sigma_P (r_1 \times r_2 \times \cdots \times r_m)$

(B) $\pi_{a_1, a_2 \ldots a_n} \sigma_P (r_1 r_2 \times \cdots \times r_m)$

(C) $\pi_{a_1, a_2 \ldots a_n} \sigma_P (r_1 \cup r_2 \cup \times \ldots \times \cup r_m)$

(D) $\pi_{a_1, a_2 \ldots a_n} \sigma_P (r_1 r_2 \times \ldots \times r_m)$

20. Let $R_1(A, B, C)$ and $R_2(D, E)$ be two relation schemas with primary keys A and D and C be a foreign key in R_1 referring to R_2. Suppose there is no violation of the above referential integrity constraint in the instances r_1 and r_2, which of the following relational algebra expression would necessarily produce an empty relation?
(A) $\pi_D(r_2) - \pi_C(r_1)$
(B) $\pi_C(r_1) - \pi_E(r_2)$
(C) $\pi_D(r_1 \bowtie_{C=D} r_2) - \pi_B(r_1)$
(D) $\pi_C(r_1 \bowtie_{C=E} r_2)$

21. Let r be an instance for the schema $R = (A, B, C, D)$. Let $r_1 = \pi_{A,B,C}(r) r_2 = \pi_{A,D}(r)$ and $S = r_1 \bowtie r_2$. Also given that the decomposition of r into r_1 and r_2 is lossy, which of the following is true?

(A) $S \subset r$	(B) $r \cup s = r$
(C) $r \subset s$	(D) $r \bowtie s = s$

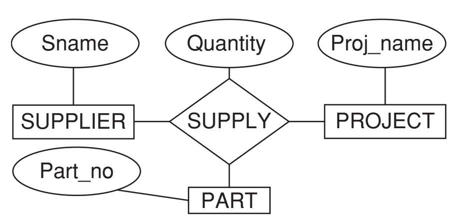
22. Which of the following is/are logical database structures?

(A) Network	(B) Tree
(C) Chain	(D) All of the above

23. A relational database management system manages data in more than one file at a time by using which of the following combinations?
(A) Tables and tuples
(B) Relations and tuples
(C) Tables and Relations
(D) Attributes and tuples

24. Let Emp = (Name, ID, ADDRESS, PHONE, SPOUSE, LIVINGAT) be a relation scheme with following FDs, which one of the following is a key
ADDRESS $\rightarrow$ Phone
SPOUSE $\rightarrow$ NAME
SPOUSE, ADDRESS $\rightarrow$ PHONE
NAME $\rightarrow$ ID
(A) ADDRESS, PHONE
(B) SPOUSE, ADDRESS
(C) NAME, SPOUSE
(D) NAME, ADDRESS

25. Consider the following E-R diagram



Select the most appropriate statement from the following for the above ER diagram:

(A) Represents a ternary relationship
(B) Represents a binary relationship
(C) Represents a ternary relationship with instances of the form (s, j, p)
(D) Represents 1 – to – many relationships

26. If two relations R_1 and R_2 are such that they are of the same degree and domain of the corresponding fields are also the same, then which one of the following is true about R_1 and R_2?
(A) $R_1 \subset R_2$
(B) $R_1 \cup R_2 = R_2 \cup R_1$
(C) R_1 and R_2 are union compatible
(D) None of these

Common data questions for 27 and 28: Let Employee and Guests be two relations with attributes (id, mobl_no, name, address) and (id, mob–no, comps_working, shifts) Relations respectively {id, mob_no} is the key for both.

27. Which of the following queries are equivalent?
(i) π_{id} (Employee $\bowtie$ Guests)
(ii) π_{id} (Employee) $\bowtie$ π_{id}(Guests)
(iii) π_{id}{(Employee–Guest) $\cap$ Guest–Employee)}
(iv) π_{id} { $\pi_{\text{id, mob}}$ (Employee) $\cap$ $\pi_{\text{id, mob}}$ (Guest)}
(A) (ii) and (iii)
(B) (ii), (iii) and (iv)
(C) (i), (ii) and (iv)
(D) (ii) and (iv) only

28. What does the following relational algebra expression represent?
π_{id} ($\pi_{\text{id, mob\_no}}$(Employee–Guests))
(A) Id of all employees working with the company
(B) Id of all permanent employees
(C) Id of part time employees
(D) None of these

Common data for questions 29 and 30:

29. Let R_1 and R_2 be two relations with attributes a_1 and a_2. P_1 and P_2 be two predicates.
Select the expression from the following which is wrong:
(A) $\sigma_{P_1}(\sigma_{P_1}(R_1)) \to \sigma_{P_2}(\sigma_{P_2}(R_1))$
(B) $\sigma_{P_1}(\pi_{a_1}(R_1)) \to \pi(\sigma_{a_1}(\sigma_{P_1}(R_1)))$
(C) $\sigma_{P_1}(R_1 \cup R_2) \to \sigma_{P_1}(R_1) \cup \sigma_{P_2}(R_2)$
(D) $\pi_{a_2}(\sigma_{a_1}(R_1)) \to \sigma_{P_1}(\pi_{a_2}(R_1))$

30. Select from the following corresponding TRC for the wrong expression in the above question:
(A) $\{t/ \exists u, R_1(t[P_1]) = R_2(u[P_1])\}$
(B) $\{t/ \forall u, R_1(t[P_1]) = R_1(u[P_1])\}$
(C) $\{t/ \exists u, R_1(t[P_1]) \neq R_2(u([P_1])\}$
(D) $\{t/\square(t \in R_1)\}$

Answer Keys

1. D	**2.** D	**3.** C	**4.** C	**5.** B	**6.** B	**7.** C	**8.** B	**9.** B	**10.** A
11. B	**12.** C	**13.** B	**14.** A	**15.** C	**16.** A	**17.** D	**18.** C	**19.** A	**20.** A

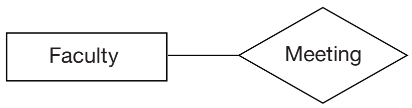
Database Test I

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

Questions 1 to 15 carry one mark each:

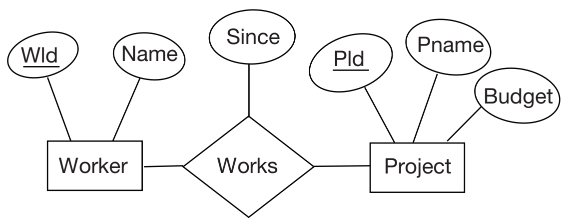
1. Consider the given ER-Diagram



The given ER-Diagram represents

(A) Unary Relationship (B) Binary Relationship
(C) Ternary Relationship (D) None of the above

2. Consider the given ER-Diagram:



Which of the following is the descriptive Attribute?

(A) WId (B) Since
(C) PId (D) {WId, PId}

3. Which of the following statements is FALSE about "Weak Entity"?

(A) A weak entity can be identified uniquely only by considering some of its attributes in conjunction with the primary key of another Entity.
(B) The owner entity set and the Weak entity set must participate in a one-to-many relationship set.
(C) One owner entity is associated with one or more weak entities, but each weak entity has a single owner.
(D) The weak entity set may/may not have total participation in the identifying relationship set.

4. Consider the given Relation schema:
Student (RNo: integer, sname: string, login: string, age: integer, grade: char(1), parent-name: string, percentage: Real).
What is the "Arity" of given Relation schema?

(A) 2, 3, 1, 1 (B) 7
(C) 3, 4 (D) 6

5. Which of the following specifies "Cardinality" of a Relation?

(A) The number of fields in a Relation
(B) The number of columns in a Relation
(C) The number of Tuples in a Relation
(D) Both (A) and (C)

6. Consider the following table:
Sailor

Sname	Rating	Age
Yashu	9	35
Lalit	10	45
Yashu	9	40
Bose	8	41

How many tuples are returned by following expression,
$\pi_{\text{Sname, Rating}}$ (Sailor)

(A) 4 (B) 3
(C) 2 (D) 1

7. Which of the following statement is FALSE, for 2 Relations R and S?

(A) RXS returns a Relation with all the fields of R in the same order as they appear in R followed by all the fields of S in the same order as they appear in S.
(B) The fields in RXS have the same domains as the corresponding fields in R and S.
(C) $R \cap S = R - (R - S)$
(D) $R \cap S = S - (S - R)$

8. Which of the following correctly describes "Prime Attribute"?

(A) It should be a part of primary key
(B) It should be a part of any candidate key
(C) It should be a part of every candidate key
(D) None of the above.

9. Let X, Y and Z denote sets of attributes over a relation schema R. Match the following.

I. If $X \to Y$, then $XZ \to YZ$ for any Z
II. If $X \supseteq Y$, then $X \to Y$
III. If $X \to YZ$, then $X \to Y$ and $X \to Z$
P. Reflexivity
Q. Augmentation
R. Decomposition

(A) I–Q, II–P, III–R (B) I–P, II–R, III–Q
(C) I–P, II–Q, III–R (D) I–R, II–Q, III–P

10. Which of the following are additional features of SQL?

(A) SQL has language constructs for specifying views, also known as virtual tables, using the CREATE VIEW Statement
(B) SQL and Relational databases can interact with new technologies such as XML and OLAP.
(C) SQL has Language constructs for creating triggers
(D) All the above

11. Consider the given Functional Dependencies for Employee – Project Relation:
ENo $\to$ EName
PNo $\to$ PName, Location

{ENo, PNo} $\rightarrow$ Hours
How many attributes appear in the closure of ENo, (ENo^+)?
(A) 1 (B) 2
(C) 3 (D) 5

12. Magnetic tapes are sequential access devices, to access the n^{th} block on tape _____?
(A) We must scan over the preceding $(n - 1)$ blocks
(B) We can scan directly n^{th} block
(C) We must scan atleast $\frac{n}{2}$ blocks before scanning n^{th} block
(D) We must scan atmost $\frac{n}{2}$ blocks before scanning n^{th} block

13. What is the unused space in each block, for fixed length record of size 'R' bytes with $B \geq R$ (B = Block Size), we can fit $\lfloor B/R \rfloor$ ($bfr = \lfloor B/R \rfloor$) records in one block?
(A) $B - (bfr * R)$ (B) $(B - bfr * R) + 1$
(C) $B + (bfr * R)$ (D) $\frac{B}{bfr} + R$

14. To utilize the unused space in each block, we can store part of a record on one block and the rest on another, A pointer at the end of the first block points to the block containing the remaining part of record, what this organization is called?
(A) Unspanned (B) Spanned
(C) Distributed (D) Collabarative

15. For variable length records using spanned organization, each block may store different number of records. The blocking factor "bfr" represents the average number of records per block for the file, what is the number of blocks 'b' needed for a file of 'r' records?
(A) $b = \left\lceil \frac{bfr}{r} \right\rceil$ (B) $b = \left\lceil \frac{r}{bfr} \right\rceil$
(C) $b = \lceil r \times bfr \rceil$ (D) $b = \left\lceil \frac{2 \times r}{bfr} \right\rceil$

16. Which of the following SQL Query is valid to increment the age of the student whose student Id (Sid) is 63078?
(A) Update student S
SET S.age = S.age + 1;
WHERE S.Sid = 63078
(B) Select S.age + 1
From student S
Where S.Sid = 63078
(C) Update S.age = S.age + 1
WHERE S.Sid = 63078
(D) Both (A) and (B)

17. Consider the given Relation worker
Worker

WId	Name	Service	Age

To Rename table as Employee or WId as EId, service as Experience, which of the following is not valid?
(A) ρ_{Employee} worker
(B) $\rho_{\text{(EID, Experience)}}$ worker
(C) $\rho_{\text{(EID, Name, Experience, Age)}}$ worker
(D) $\rho_{\text{Employee (EID, Name, Experience, Age)}}$ worker

18. Consider the given schema for sailors
sailors(Sid : integer, Sname : string, Rating : integer, age : real).
Which of the following SQL Queries is invalid?
(A) SELECT S.Rating, (S.age)
FROM Sailors S
WHERE S.Rating = 10
(B) SELECT S.Rating, MAX (S.age)
FROM Sailors S
GROUPBY S.Rating
(C) SELECT S.Sname, MAX (S.age)
FROM Sailors S
WHERE S.Rating > 7
(D) SELECT AVG (S.Age)
FROM Sailors S
WHERE S.Rating > 8

19. Consider the schema given in the above Question,
SELECT Sname
FROM Sailors
WHERE Rating IN(6, 8, 9, 10)
What is retrieved by the above query?
(A) The names of sailors whose Rating is between 6 and 10.
(B) The names of sailors whose Rating is any one of 6, 8, 9, 10.
(C) Both (A) and (B)
(D) None of the above

20. Let 'R' be a Relation schema and Let x and y be non empty sets of attributes in R. An instance 'r' of R satisfies the FD $-x \rightarrow y$. For which of the following tuples t_1 and t_2 are in r?
(A) $t_1 \cdot x = t_2 \cdot x$ and $t_1 \cdot y = t_2 \cdot y$
(B) $t_1 \cdot x = t_2 \cdot y$ and $t_1 \cdot y = t_2 \cdot y$
(C) $t_1 \cdot x = t_2 \cdot x$ and $t_1 \cdot y = t_2 \cdot x$
(D) $t_1 \cdot x = t_2 \cdot y$ and $t_1 \cdot x = t_2 \cdot y$

21. Consider the following Relational instance?

A	B	C	D
a_1	b_1	c_1	d_1
a_1	b_1	c_1	d_2
a_3	b_2	c_3	d_1
a_2	b_3	c_2	d_4

Which of the following are satisfied by the given instance?
(A) $AB \rightarrow C$ (B) $AB \rightarrow CD$
(C) $AC \rightarrow D$ (D) $D \rightarrow AC$

22. Consider the given Relation R

R

W	X	Z
W_1	X_1	Z_1
W_2	X_2	Z_2
W_3	X_2	Z_1

$\pi_{wx}(R)\ x\ \pi_{xz}(R)$, what is the number of tuples returned by the given expression?

(A) 2 (B) 3
(C) 4 (D) 5

23. For the Relation 'R' given in the above question, if we perform $\pi_{wx}(R) ⟕ \pi_{xz}(R)$ (⟕ : left outer join), what is the number of tuples that appear in the Result?

(A) 0 (B) 3
(C) 5 (D) 6

24. Consider the given SQL Query:
Select DISTINCT ENo
From works
Where (PNo, Hours) IN (Select PNo, Hours
From works where ENo = '788');
What is returned by the above query?

(A) The employee numbers of all employees who work on the same (PNo, Hours) combination on some project on which Employee ENo 788 is working.
(B) The employee numbers of all employees who work on the same (PNo, Hours) combination whose ENo is 788.
(C) Both (A) and (B)
(D) None of the above

25. Retrieve the Employee numbers (ENo) of all employees who work on project numbers 11, 22, 23, 24?

(A) SELECT ENo
FROM Works
Where PNo IN(11, 22, 23, 24)
(B) Select DISTINCT ENo
From Works
Where PNo IN(11, 22, 23, 24)
(C) Select ENo
FROM Works
Where PNo = 11 AND PNo = 22 AND PNo = 23 AND PNo = 24.
(D) Select *
FROM works
Where PNo = 11 OR PNo = 22 OR PNo = 23 OR PNo = 24.

26. Which of the following correctly specifies the "JOIN" Operation on 2 tables Employee and Department, the common field in both tables is DNo?

(A) Select *
From (Employee JOIN Department ON Employee.DNo = Department.DNo)
(B) Select *
From (Employee JOIN Department)
(C) Select *
From Employee, Department
(D) Select *
From (Employee JOIN Department IN Employee.DNo = Department.DNo)

27. Consider the given Functional Dependencies for Employee – project Relation
ENo → EName
PNo → PName, Location
{ENo, PNo} → Hours
How many attributes are included in the closure of $\{ENo, PNo\}^+$?

(A) 2 (B) 4
(C) 5 (D) 6

Common data for Questions 28 and 29:
Consider the 2 tables T_1 and T_2

Table T_1

P	Q	R
20	X	50
25	Y	80
35	X	60

Table T_2

A	B	C
20	Y	60
35	Z	30
20	Y	50

28. What is the number of tuples returned from
$T_1 \bowtie (T_1 \cdot P = T_2 \cdot A \text{ AND } T_1 \cdot R = T_2 \cdot C) T_2$?

(A) 0 (B) 1
(C) 2 (D) 3

29. What is the number of tuples returned from
$T_1 \bowtie (T_1 \cdot P = T_2 \cdot A \text{ OR } T_1 \cdot R = T_2 \cdot C)\ T_2$?

(A) 1 (B) 2
(C) 3 (D) 4

Common data for Questions 30 and 31:
Consider the given Relation worker:

Name	Age	Project-Number
Anu	26	10
Bala	24	20
Sudhir	28	10
Shreya	24	10
Bharat	19	20
Srinath	21	30
Raj	22	30
Mishra	21	20
Phani	19	40

30. What is the Result of the following SQL Query
SELECT Project-Number, MIN (Age)

FROM Worker
GROUPBY Project-Number
HAVING COUNT (*) ≥ 3

(A)

Project-Number	MIN (Age)
10	24
20	19

(B)

Project-Number	MIN (Age)
10	24
20	19
30	21
40	19

(C)

Project-Number	MIN (Age)
10	24
20	19
30	21

(D)

Project-Number	MIN (Age)
20	19
40	19

31. In the Result of following SQL query
SELECT Age, count (*)
FROM Worker
GROUPBY Age
What is the number of tuples?
(A) 4 (B) 5
(C) 6 (D) 9

Common data for Questions 32 and 33:
Consider the given 2 tables:

Sailor-1:

Sname	Rating	Age
Yashu	9	35
Lalit	10	45
Bose	8	41
Ana	7	40

Sailor-2

Sname	Rating	Age
Raj	10	40
Kamal	10	41
Ana	7	40

32. Which of the following Tuple is not part of sailor-1 and sailor-2?

(A)

Yashu	9	35	Kamal	10	41

(B)

Lalit	10	45	Raj	10	40

(C)

Ana	7	40	Kamal	7	40

(D)

Bose	8	41	Lalit	10	45

33. What is the number of tuples appear in sailor-1 SET DIFFERENCE sailor-2?
(A) 0 (B) 1
(C) 2 (D) 3

Common Data for Questions 34 and 35:
Consider the given 2 tables Employee and Department and primary keys are shown with underline.

Employee

EId	Name	DNo	Age
0326	Kumar	5	38
0429	Nilesh	4	36
0589	Phani	4	34
0679	Raja	3	36
0588	Deepak	2	37

Department

DNo	DName
1	Accounts
2	Sales
3	Marketing
4	Executives
5	Research

34. Insert into Employee values < 0589, 'Anurag', 3, 37 >, The above operation violates which constraint?
(A) NOT NULL Constraint
(B) KEY Constraint
(C) Entity Integrity Constraint
(D) Referential Integrity Constraint

35. Delete Department tuple with DNo = 5, The above operation violates which constraint?
(A) NOT NULL Constraint
(B) KEY Constraint
(C) Referential Integrity Constraint
(D) Entity Integrity Constraint

Answer Keys

1. A	**2.** B	**3.** D	**4.** B	**5.** C	**6.** B	**7.** D	**8.** B	**9.** A	**10.** D
11. B	**12.** A	**13.** A	**14.** B	**15.** B	**16.** D	**17.** B	**18.** C	**19.** B	**20.** A
21. A	**22.** D	**23.** C	**24.** A	**25.** B	**26.** A	**27.** D	**28.** B	**29.** D	**30.** A
31. C	**32.** D	**33.** D	**34.** B	**35.** C					

Hints and Explanations

1. If only one entity is participating in a relationship that relation is called Unary Relation. Choice (A)
2. Descriptive attributes are used to record information about the relationship, rather than about any one of the participating entities. Suppose we wish to record that a particular worker is working for a project since 1993; This information is captured by adding an attribute "since" to works. Choice (B)
3. The weak entity set must have total participation in the identifying relationship set. Choice (D)
4. The degree is also called "Arity" of a relation, is the number of fields (or) columns, There are '7' fields. Choice (B)
5. The "cardinality" of a relation instance is the number of tuples in it. The degree of the relation is the number of fields (or) columns. Choice (C)
6. π-project, eliminates duplicates

Sname	Rating
Yashu	9
Lalit	10
Bose	8

$\therefore$ Hence '3' tuples. Choice (B)

7. $R \cup S = S - (S - R)$ is not TRUE. Choice (D)
8. Prime Attributes should be part of any candidate key. Choice (B)
9. Choice (A)
10. All the statements are additional features of SQL. Choice (D)
11. $ENo^{+} = \{ENo, EName\}$. Choice (B)
12. We must scan over the preceding $(n - 1)$ blocks. Choice (A)
13. $B - (bfr * R)$ is the unused space in each block. Choice (A)
14. It is called spanned organization. Choice (B)
15. $b = \left\lceil \left(\frac{r}{bfr} \right) \right\rceil$ Choice (B)
16. We can modify the column values in an existing row using the UPDATE command. We can increment the age of the student with Sid 63078

UPDATE Student S
SET S.age = S.age + 1
WHERE S.Sid = 63078

(or)

Select S.age + 1
From Student S
Where S.Sid = 63078. Choice (D)

17. $\rho_{(EID,\ Experience)}$ worker
It will replace WID with EID and Name with Experience which is NOT Valid. Choice (B)
18. If select clause uses an aggregate operation, then it must only use aggregate unless the query contains a GROUP BY clause. Choice (C)
19. It retrieves the names of sailors whose Rating is any one of the given Ratings 6, 8, 9, 10. Choice (B)
20. $t_1 \cdot x = t_2 \cdot x$ and $t_1 \cdot y = t_2 \cdot y$. Choice (A)
21. The given instance satisfies $AB \to C$. Choice (A)
22. $\pi_{wx}(R)$

W	X
W_1	X_1
W_2	X_2
W_3	X_2

$\pi_{XZ}(R)$

X	Z
X_1	Z_1
X_2	Z_2
X_2	Z_1

$\pi_{wx}(R) (\bowtie) \pi_{xz}(R)$

W	X	Z
W_1	X_1	Z_1
W_2	X_2	Z_2
W_2	X_2	Z_1
W_3	X_2	Z_2
W_3	X_2	Z_1

Choice (D)

23. All tuples in $\pi_{wx}(R)$ has atleast one matching in $\pi_{xz}(R)$, so same number of tuples as $\pi_{wx} \bowtie \pi_{xz}(R)$, returned in the result. Choice (C)
24. The employee numbers of all employees who work on the same (PNO, Hours) combination on some project on which employee ENO 788 is working. Choice (A)
25. Some employees may work on more than one project, so DISTINCT Key word will eliminate duplicates in the output. Choice (B)
26. The concept of Joining Relations was incorporated into SQL to permit users to specify a table resulting from a Join operation in the FROM clause of a query. Choice (A)
27. $\{ENo, PNo\}^{+} = \{ENo, PNo, EName, PName, Location, Hours\}$. Choice (D)

28. $T_1 \bowtie T_2$

P	Q	R	A	B	C
20	X	50	20	Y	60
20	X	50	35	Z	30
20	X	50	20	Y	50
25	Y	80	20	Y	60
25	Y	80	35	Z	30
25	Y	80	20	Y	50
35	X	60	20	Y	60
35	X	60	35	Z	30
35	X	60	20	Y	50

Only 1(3^{rd} tuple). Choice (B)

29. Refer the table given in the above solution.

$T_1 \cdot P = T_2 \cdot A$

1^{st}, 3^{rd}, 8^{th} tuples

$T_1 \cdot R = T_2 \cdot C$

7th tuple

∴ Total '4' tuples. Choice (D)

30. GROUP-BY Project-Number gives

Table-1

Name	Age	Project-Number
Anu	26	10
Sudhir	28	10
Shreya	24	10

Table-2

Name	Age	Project-Number
Bala	24	20
Bharat	19	20
Mishra	21	20

Table-3

Name	Age	Project-Number
Srinath	21	30
Raj	22	30

Table-4

Name	Age	Project-Number
Phani	19	40

Table-1 and Table-2 are satisfying the condition count (*) ≥ 3. Choice (A)

31. GROUP-BY Age returns

Anu	26

Sudhir	28

Bala	24
Shreya	24

Bharat	19
Phani	19

Srinath	21
Mishra	21

Raj	21

Result:

Age	Count (*)
19	2
21	2
22	1
24	2
26	1
28	1

Choice (C)

32. The tuple $\boxed{\text{Bose} \mid 8 \mid 41}$ cannot have cross product with any tuple in sailor-1. Choice (D)

33. It returns the tuples that are present in sailor-1 but not in sailor-2, $\boxed{\text{Ana} \mid 7 \mid 40}$ is present in sailor-1 and sailor-2 also, so this will not appear in the Result of sailor-1 SET DIFFERENCE sailor-2. Choice (D)

34. It violates KEY constraint, because EID is primary key and EID 0589 is already present in the employee table. Choice (B)

35. Employee table references to Department table, Absence of DNo = 5 causes Referential Integrity Constraint violation. Choice (C)

Database Test 2

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. If the database operations in a transaction do not update the database but only retrieve data, what is that transaction called?
(A) Write-only operation (B) Read-only operation
(C) Named data item (D) Granularity

2. Consider the 2 interleaved transactions T_1 and T_2:

T_1	T_2
$r_1(x)$	
$w_1(x)$	
	$r_2(x)$
$r_1(y)$	
$w_1(y)$	
	$r_2(y)$
C_1	
	C_2

Which of the following is schedule for the above?
(A) $r_1(x), r_2(x), w_1(x), r_1(y), w_1(y), r_2(y), C_1, C_2$
(B) $r_1(x), w_1(x), r_2(x), r_1(y), w_1(y), r_2(y), C_1, C_2$
(C) $r_1(x), w_1(x), r_2(x), r_1(y), w_1(y), r_2(y), C_2, C_1$
(D) $r_1(x), w_1(x), r_2(x), r_1(y), r_2(y), w_1(y), C_1, C_2$

3. Two operations in a schedule are said to have conflict if
I. They belong to different transactions.
II. They access the same data item.
III. Atleast one of the operations is write operation.
IV. Atleast one of the operations is Read operation.
Which of the following is TRUE?
(A) I and II only (B) II and III only
(C) I, II and III only (D) II, III and IV only

4. A Non recoverable schedule must contain which of the following conflict?
(A) RR conflict (B) RW conflict
(C) WR conflict (D) WW conflict

5. Consider the given schedule:

T_1	T_2
$r_1(x)$	
$w_1(x)$	
$r_1(y)$	
C_1	
	$r_2(x)$
	$w_2(x)$
	C_2

The given schedule is
(A) Cascadeless schedule
(B) strict schedule
(C) Non-serial schedule
(D) Non-Recoverable schedule

6. In a schedule, transactions can neither read nor write an item 'X' until the last transaction that wrote X has committed or Aborted, what is that schedule?
(A) Cascadeless schedule (B) Strict schedule
(C) Recoverable schedule (D) Non serial schedule

7. Consider the given schedule

T_1	T_2
$R(x)$	
$x = x - N$	
$w(x)$	
	$r(x)$
	$w(x)$
$r(y)$	

What is the number of WR conflicts present in the given schedule?
(A) 0 (B) 1
(C) 2 (D) 3

8. Which of the following protocol is based on locking data items to prevent concurrent transactions from interfering with one another, and enforcing an additional condition that guarantees serializability?
(A) 1 PL (B) 2 PL
(C) 3 PL (D) 4 PL

9. In Random access, for accessing a disk block on a disk, what is the Rotational delay if disk rotates at 10000 rpm (rotations per minute)?
(A) 6 m/sec (B) 9 m/sec
(C) 3 m/sec (D) 12 m/sec

10. Whenever 2 independent 1:N relationships A:B and A:C are mixed in the same relation, then which of the following is TRUE?
(A) A Transitive Dependency may arise
(B) A Partial Dependency may arise
(C) A Multi-valued Dependency may arise
(D) None of the above

11. Which of the following is TRUE about 2NF?
(A) A relation schema R is in 2 NF, if every non prime attribute A in R is not partially dependent on any key of R.
(B) If the primary key contains a single attribute, the test need not be applied at all.
(C) Test for 2NF involves testing for functional dependencies whose left-hand side attributes are part of the primary key.
(D) All the above

12. Consider the following *FD*'s:

$X \rightarrow Y$

$WY \rightarrow Z$

If pseudo transitive rule is applied on given *FD*'s, what is the result?

(A) $X \rightarrow Z$ (B) $XW \rightarrow Z$

(C) $XY \rightarrow Z$ (D) $XWY \rightarrow YZ$

13. What is the average time to access a specific Record in a file using sequential scan (Linear search) on unordered file? (Assume that there are '*b*' blocks)

(A) $b/2$ (B) b

(C) $\log_2 b$ (D) $2b$

14. In which hashing technique, a type of directory, an array of '2^d' bucket addresses is maintained, where '*d*' is called the global depth of the directory?

(A) Internal Hashing (B) Extendible Hashing

(C) Separate Chaining (D) Static Hashing

15. Assume that, a primary index is built on a file with 45 blocks, what is the number of block accesses required to search for a specific Record in a file (Using Binary search)?

(A) 45 (B) 23

(C) 6 (D) 7

16. Consider the given 2 schedules:

S_a: $r_1(x), w_1(x), r_2(x), w_1(x), w_2(x), r_1(y), C_1, C_2$

S_b: $r_1(x), w_1(x), r_2(x), w_2(x), r_1(x), C_1, C_2$

Which of the following is TRUE?

(A) Both are conflict serializable

(B) Only S_a is conflict serializable

(C) Only S_b is conflict serializable

(D) Both are not conflict serializable

17. Consider the given transaction T_1, that follows 2-phase Locking protocol:

T_1
1. Read – Lock(X)
2. Read – item (X)
3. Write – Lock(Y)
4. Unlock(X)
5. Read – item(Y)
6. Y = X + Y
7. Write – item(Y)
8. Unlock(Y)

Which of the following is TRUE?

(A) Record 1 to Record 3 is Growing phase

(B) Record 4 to Record 8 is shrinking phase

(C) Record 1 to Record 4 is Expanding phase

(D) Both (A) and (B)

18. Consider a disk with track size 70 Kbytes and it rotates at 3600 rpm, what is the transfer rate in bytes/m sec?

(A) 3500 (B) 3600

(C) 4200 (D) 4500

19. What is the time required to transfer consecutively '*k*' non contiguous blocks that are on the same cylinder, where '*S*' is seek time, '*rd*' is rotational delay and '*btt*' is block transfer time?

(A) $S + (k * (rd + btt))$ msec

(B) $(S + rd + btt)$ msec

(C) $S + rd + (k * btt)$ msec

(D) $S + (k * rd) + btt$ msec

20. What is the estimate for transferring consecutive blocks (include interblock gap), the disk manufacturer provides a bulk transfer rate (btr) that takes the gap size into account when reading consecutively stored blocks (B), and the gap size is *G* bytes?

(A) btr = $(B/(B + G))$ * tr bytes/msec

(B) btr = $(B/(B + G))$ bytes/msec

(C) btr = $(B + G)$ + tr bytes/msec

(D) btr = $((B + G)/B)$ + tr bytes/msec

21. Match the following:

I. 1 NF

II. 2 NF

III. 3 NF

P. No Non key attribute should be functionally dependent on a part of the primary key.

Q. Relation should have no nonatomic attributes or nested relations.

R. Relation should not have a non key attribute functionally determined by another non key attribute.

(A) I–P, II–Q, III–R

(B) I–Q, II–P, III–R

(C) I–Q, II–R, III–P

(D) I–R, II–Q, III–R

22. Consider the given Relation EMP and given functional dependencies:

$F = (E \rightarrow N$

$P \rightarrow A, L$

$E\,P \rightarrow H)$

Which of the following is Incorrect closure set with respect to *F*?

(A) $E^+ = \{E, N\}$

(B) $P^+ = \{P, A, L\}$

(C) $\{EP\}^+ = \{E, N, P, A, L, H\}$

(D) $\{EH\}^+ = \{E, N, H, P, A\}$

23. Consider the functional dependencies given in the above question, EMP Relation is in which Normal Form?

(A) 1 NF (B) 2 NF

(C) 3 NF (D) BCNF

24. Consider the given 2 tables:

Person

Name	Mobile
Anil	9848463 9440072
Raj	9004432

Student

SName	Project	
	P No.	Hours

Which of the following is TRUE?
(A) Both tables are in 1 NF
(B) Both tables are not in 1 NF
(C) Person is in 1 NF but not student
(D) Person is in 2 NF and student is in 1 NF

25. Consider the schema $R(ABCDE)$ and functional dependencies $A \rightarrow BE$, $C \rightarrow D$, then the decomposition of R into $R_1(ABE)$, $R_2(CD)$ is
(A) Dependency preserving and lossless join.
(B) Dependency preserving and not lossless join.
(C) Lossless join but not dependency preserving.
(D) Not Dependency preserving and Not lossless join.

26. Consider a relation $R(A, B, C, D, E)$ with the following Dependencies:
$A \rightarrow C$
$BCD \rightarrow E$
$DE \rightarrow B$
Identify the candidate keys from the following options?
(A) AD, ADB (B) ADB, ADC
(C) ADB, ADE (D) ADC, ADE

27. Consider the Functional Dependencies given in the above question, which of the following are "Prime Attributes"?
(A) $ABCD$ (B) $ABCE$
(C) $ABDE$ (D) $ACDE$

28. Consider a file with fixed length records, one sample record is given below,

Name	E No	Salary	Department

1 14 18 22 32

The file contains 32000 records, and it is stored on a disk with block size 1024 Bytes, what is the blocking factor?
(A) 16 (B) 32
(C) 64 (D) 128

29. Consider a file with Fixed length Records, one sample record is given below.

Name	E No	Salary	Department	Remarks	Total

1 14 18 22 32 64

The file contains 30000 records, what is the number of blocks required to store the file, on a disk with block size 2048 bytes?
(A) 648 (B) 840
(C) 938 (D) 968

30. Construct a B-tree with 6, 4, 5, 9, 7, 2 values, order of B-tree is $P = 3$, what is the maximum number of node splits?
(A) 1 (B) 2
(C) 3 (D) 4

31. Consider a disk with block size $B = 512$ bytes, number of tracks per surface is 400, this disk pack consists of 16 double sided disks, How many cylinders are there?
(A) 100 (B) 200
(C) 400 (D) 800

Common Data Questions 32 and 33:
Consider the given schedules
S_1: $r_1(P)$, $r_2(R)$, $r_1(R)$, $r_3(P)$, $r_3(Q)$, $w_1(P)$, C_1, $w_3(Q)$, C_3, $r_2(Q)$, $w_2(R)$, $w_2(Q)$, C_2
S_2: $r_1(P)$, $r_2(R)$, $r_1(R)$, $r_3(P)$, $r_3(Q)$, w_1(P), $w_3(Q)$, $r_2(Q)$, $w_2(R)$, $w_2(Q)$, C_1, C_2, C_3.

32. Which of the following is/are Recoverable schedule(s)?
(A) Only S_1 (B) Only S_2
(C) Both S_1 and S_2 (D) Neither S_1 nor S_2

33. Which of the following is/are "cascadeless" schedules(s)?
(A) Only S_1
(B) Only S_2
(C) Both S_1 and S_2
(D) Neither S_1 nor S_2

Linked Answer Questions 34 and 35:
Consider the given table:
Student

Sname	Course	Department
Arun	C_1	D_1
Arun	C_2	D_1
Arun	C_1	D_2
Arun	C_2	D_2

34. Student table has multivalved dependencies, which of the following is correct 4 NF Decomposition?
(A) Student 1 (Sname, course)
Student 2 (Course, Department)
(B) Student 1 (Sname, Department)
Student 2 (course, Department)
(C) Student 1 (sname, course)
Student 2 (sname, Department)
(D) Student 1 (sname, course)
Student 2 (sname, Department)
Student 3 (Course, Department)

35. Which of the following is TRUE, for the above identified correct answer?
(A) student 1 ⋈ student 2, returns student table
(B) student 1 X student 2 returns student table
(C) student 1 ⋈ student 2 returns student table
(D) None of the above

Answer Keys

1. B	**2.** B	**3.** C	**4.** B	**5.** A	**6.** B	**7.** B	**8.** B	**9.** C	**10.** C
11. D	**12.** B	**13.** A	**14.** B	**15.** D	**16.** D	**17.** D	**18.** C	**19.** A	**20.** A
21. B	**22.** D	**23.** A	**24.** B	**25.** B	**26.** C	**27.** C	**28.** B	**29.** C	**30.** B
31. C	**32.** A	**33.** A	**34.** C	**35.** A					

Hints and Explanations

1. Read only operation do not update the database but only retrieves data. Choice (B)

2. Correct schedule is:
$r_1(x)$, $W_1(x)$, $r_2(x)$, $r_1(y)$, w_1 (y), $r_2(y)$, C_1, C_2
Choice (B)

3. Two operations in a schedule are said to have conflict if they satisfy I, II and III.
Choice (C)

4. Recover ability can be decided by the presence of 'RW' conflict in a schedule.
Choice (B)

5. A schedule is said to be cascadeless, if every transaction in the schedule reads only items that were written by committed transactions. Choice (A)

6. More restrictive type of schedule is called a strict schedule, in which transactions can neither read nor write an item 'X' until the last transaction that wrote 'X' has committed or aborted.
Choice (B)

7.

RW

$r_1(x)$, $w_1(x)$, $r_2(x)$, $w_2(x)$, $r_1(y)$

WR

WW

$\therefore$ One WR conflict is present. Choice (B)

8. 2 PL (2 phase Locking protocol) ensures serializability. Choice (B)

9. If the speed of disk rotation is 'P' revolutions per minute (rpm), then the average rotational delay 'rd' is given by
$rd = (1/2) * (1/P)$ min $= (60 * 1000)/(2 * P)$ msec
$rd = 3$ msec Choice (C)

10. If 2 independent 1:N relationships A:B and A:C are mixed in the same Relation, a multi valued Dependency may arise. Choice (C)

11. All the statements are TRUE.
Choice (D)

12. $X \rightarrow Y$
$WY \rightarrow Z$
$XW \rightarrow Z$ Choice (B)

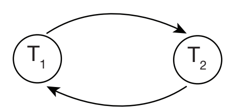
13. The average access time in block accesses to find a specific record in a file with 'b' blocks on unordered file is 'b/2'. Choice (A)

14. Hashing Technique that allows Dynamic File expansion is extendible hashing, Choice (B)

15. First search will be conducted on primary index. By using binary search,
$\Rightarrow \left\lceil \log^{45} \right\rceil \cong 6$ block accesses
6 block accesses in primary index + 1 block access in original file.
$\therefore$ 7 block accesses. Choice (D)

16. S_a: $r_1(x)$, $w_1(x)$, $r_2(x)$, $w_1(x)$, $w_2(x)$, $r_1(y)$, C_1, C_2

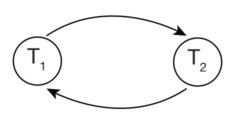
Precedence Graph:



$\therefore$ 'S_a' is not conflict serializable, since cycle is present in Precedence graph.

S_b: $r_1(x)$, $w_1(x)$, $r_2(x)$, $w_2(x)$, $r_1(x)$, C_1, C_2

Precedence Graph:



$\therefore$ S_b is not conflict serializable, since cycle is present in precedence graph. Choice (D)

17. **Expanding or growing phase:** During which new locks on items can be acquired but none can be released.
Shrinking phase: During which existing locks can be released but no new locks can be acquired.
Choice (D)

18. Transfer rate = $(70 \times 1000)/(60 \times 1000/3600)$

$$\frac{70 \times 1000}{\frac{1000}{60}} = \frac{70 \times 60 \times 1000}{1000} = 4200 \text{ bytes/msec}$$

Choice (C)

19. To transfer consecutively 'k' non contiguous blocks that are on the same cylinder, we need approximately, $S + (k * (rd + btt))$ msec. Choice (A)

20. Transferring consecutive blocks (including inter block gap)
$\Rightarrow$ btr = $(B/(B + G))$ * tr bytes/msec Choice (A)

21. I – Q, II – P, III – R is correct match. Choice (B)

22. $\{EH\}^+$ cannot determine P and A. Choice (D)

23. The key for EMP is $\{EP\}$ and the functional Dependencies. $E \rightarrow N$
$P \rightarrow A, L$ are partial dependencies.
$\therefore$ EMP is not in 2NF i.e., it is in 1 NF. Choice (A)

24. Both tables are not in 1 NF, person table has multiple values under mobile column for one name, In student relation, there is another relation project, A relation within a Relation is not allowed in 1 NF. Choice (B)

25. It is Dependency preserving, $A \rightarrow BE$ is in R_1 and $C \rightarrow D$ is in R_2.
Checking for loss less join:

	A	B	C	D	E
R_1(ABE)	*	*			*
R_2(CD)			*	*	

It is Not Loss Less JOIN. Choice (B)

26. $A \rightarrow C$
$BCD \rightarrow E$
$DE \rightarrow B$

L	M	R
AD	BCE	

$\{AD\}^+ = \{ADC\}$
$ADB^+ = \{ADBCE\}$
$ADC^+ = \{ADC\}$
$ADE^+ = \{ADECB\}$ Choice (C)

27. Candidate keys are: ADB, ADE
Prime Attributes are part of any candidate key, $ABDE$
Choice (C)

28. Blocking factor is defined as, the number of records stored on one block.

$$Bfr = \left\lfloor \frac{1024}{32} \right\rfloor = \left\lfloor \frac{2^{10}}{2^5} \right\rfloor = 2^5 = 32 \text{ Records}$$

Choice (B)

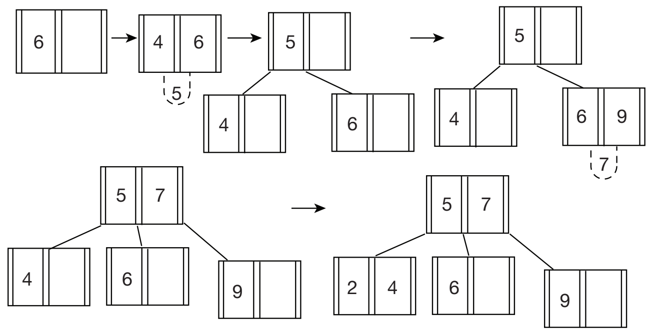
29. Blocking Factor

$$= \left\lfloor \frac{2048}{64} \right\rfloor = \left\lfloor \frac{2^{11}}{2^6} \right\rfloor = 2^5 = 32 \text{ records/block}$$

Number of blocks required:
1 block --------- 32 records
x ----------------- 30000 records

$$x = \left\lceil \frac{30000}{32} \right\rceil = \lceil 937.5 \rceil = 938 \text{ blocks}$$ Choice (C)

30. Order $P = 3$



$\therefore$ 2 Node splits Choice (B)

31. Cylinders = Number of tracks that is 400 Choice (C)

32. S_1: $r_1(P), r_2(R), r_1(R), r_3(P), r_3(Q), W_1(P), C_1,$
$w_3(Q), C_3, r_2(Q), w_2(R), w_2(Q), C_2$

To check recoverability, search for RW conflict. There is one RW conflict, T_3 is performing write operation so it has to commit first.
$\therefore$ S_1 is Recoverable.
S_2: $r_1(P), r_2(R), r_1(R), r_3(P), r_3(Q), w_1(P),$
$w_3(Q), r_2(Q), w_2(R), w_2(Q), C_1, C_2, C_3.$

T_3 has to commit first but T_2 has committed first.
$\therefore$ S_2 is not a recoverable schedule. Choice (A)

33. S_1:

T_1	T_2	T_3
$r_1(P)$		
	$r_2(R)$	
$r_1(R)$		
		$r_3(P)$
		$r_3(Q)$
$w_1(P)$		
C_1		
		$w_3(Q)$
		C_3
	$r_2(Q)$	
	$w_2(R)$	
	$w_2(Q)$	
	C_2	

S_1 is cascadeless, because, data is taken from committed transactions.

S_2:

T_1	T_2	T_3
$r_1(P)$		
	$r_2(R)$	
$r_1(R)$		
		$r_3(P)$
		$r_3(Q)$
$w_1(P)$		
		$w_3(Q)$
	$r_2(Q)$	
	$w_2(R)$	
	$w_2(Q)$	
C_1		
	C_2	
		C_3

T_3 should commit before T_2

$\therefore$ S_2 is not cascadeless schedule.

Choice (A)

34. Multi valued dependencies:
Sname $\rightarrow\rightarrow$ Course, Sname $\rightarrow\rightarrow$ Department
4NF decomposition is as follows
Student 1(Sname, course)
Student 2(Sname, Department)

Choice (C)

35. Student 1 $\bowtie$ student 2 returns student table.

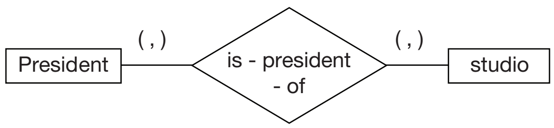
Choice (A)

Database Test 3

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

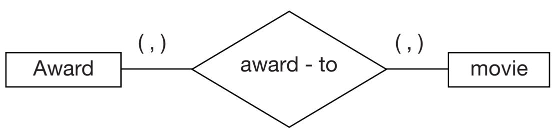
1. A studio can have at most one president and a president can preside at most one studio.



Which of the following is correct cardinality ratio, for the above description?

(A) (0, 1), (1, *n*) (B) (0, 1), (0, 1)
(C) (1, *n*), (0, 1) (D) (1, *n*), (1, *n*)

2. A movie award goes exactly to one movie. A movie may be awarded multiple awards (but may be none at all). Which of the following is correct cardinality ratio, for the above description?



(A) (0, 1), (1, *n*) (B) (1, 1), (1, *n*)
(C) (1, 1), (0, ∗) (D) (1, 1), (1, ∗)

3. Match the following:

I. Conceptual Database design
II. Logical Database design
III. Physical Database design
P. Transforms the conceptual schema into the data model supported by the DBMS.
Q. Design indexes, table distribution, buffer size etc.
R. Produces the initial model.

(A) I–R, II–P, III–Q (B) I–P, II–Q, III–R
(C) I–Q, II–P, III–R (D) I–Q, II–R, III–P

Common Data for Questions 4 and 5:

CREATE TABLE Emp (EId INT
Name CHAR(50)
mgr-Id : INT
SSNo: INT UNIQUE
DNo: INT
Salary: INT
Primary key (EId)
Foreign key DNo References Dept (DNo))

4. If a tuple is inserted into the table Emp, which violation would never occur?

(A) Key constraint
(B) Entity Integrity constraint
(C) Referential Integrity constraint
(D) Unique constraint

5. If a tuple value is updated in Emp table, which violations would never occur?

(A) Key constraint
(B) Referential Integrity constraint
(C) UNIQUE Constraint
(D) None of the above

6. Student (RNo, Name, Marks, Subject)
For each Subject, Retrieve the Subject, maximum marks in that subject.
In the SQL query which clause will not appear?

(A) SELECT
(B) GROUPBY
(C) FROM
(D) WHERE

7. Which of the following is NOT a Relational algebra operator used in basic queries?

(A) JOIN (B) PROJECT
(C) SELECT (D) LOCATE

8. What does the asterisk (∗) in SQL mean?

(A) It is a standard symbol used to start a query.
(B) It is a wild card symbol that requests inclusion of all attributes.
(C) It is an interruption symbol used to abort a query if it takes longer to process than a prescribed time length.
(D) None of the above

9. Consider the given functional dependencies

$R(A, B, C, D)$:
$FD = \{A \rightarrow B$
$C \rightarrow \text{B}$
$D \rightarrow B\}$

The given Relation is in which Normal Form?

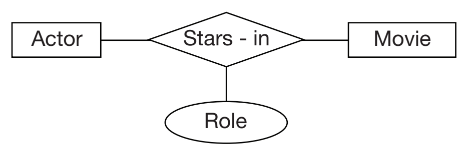
(A) 1 NF (B) 2 NF
(C) 3 NF (D) BCNF

10. For a Relation scheme R(ABC), Assume that all attributes are prime attributes, Then minimum '*R*' is in which Normal Form?

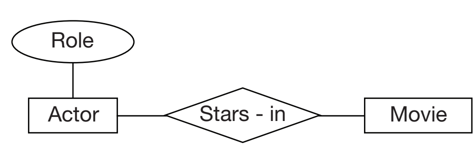
(A) 1 NF (B) 2 NF
(C) 3 NF (D) BCNF

11. Which of the following model, describes the fact that a role is stored for every pair of actor '*X*' and movie '*Y*' such that '*X*' starred in '*Y*'.

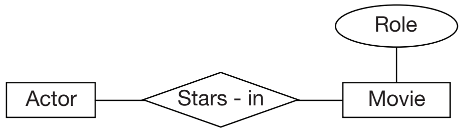
(A)



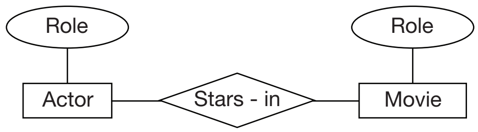
(B)



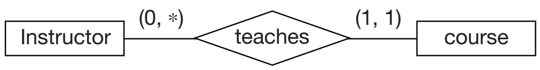
(C)



(D)



12. Consider the given ER-Diagram:



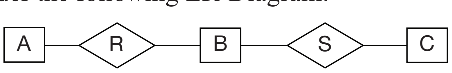
Which of the following is TRUE?
(A) one instructor teaches many courses, but each course is run by exactly one instructor.
(B) One instructor teaches atmost one course.
(C) An instructor may not take even a single course.
(D) One instructor teaches one course, but each course is run by many instructors.

13. Consider the given Functional dependencies.
For a Relation R(ABCDE):
$A \to B$
$B \to C$
$BC \to A$
$A \to D$
$E \to A$
$D \to E$
Which of the following is not a key?
(A) B (B) C
(C) D (D) E

14. Consider a Relation $R(ABCDE)$ with following functional dependencies:
$ABC \to DE$
$D \to AB$
What is the number of candidate keys for the Relation R?
(A) 0 (B) 1
(C) 2 (D) 3

15. Suppose relation $R(A, B)$ currently has tuples {(2, 3), (2, 4), (4, 5)} and Relation $S(B, C)$ currently has {(3, 6), (5, 7), (8, 9)}. What is the number of tuples in the result of the SQL query
SELECT * FROM R NATURAL OUTER JOIN S?
(A) 2 (B) 3
(C) 4 (D) 5

16. Consider the following ER-Diagram:



What is the minimum number of tables required to represent given ER-Diagram?
(A) 1 (B) 2
(C) 3 (D) 4

17. To find the EId of the Employees that are managed by people who are managed by the employee with EId 456.
Consider the following Queries:
I. SELECT E.EId
FROM Emp E, Emp F
WHERE E.MgrId = F.EId AND F.MgrId = 456
II. SELECT EId
FROM Emp
WHERE MgrId IN (SELECT EId
FROM Emp
WHERE MgrId = 456)
Which query will correctly get the desired set of Employee IDs?
(A) I only (B) II only
(C) Both I and II (D) Neither I nor II

18. Consider the following functional dependencies
$AB \to C$
$C \to D$
$AB \to D$
Which of the following is CORRECT minimal set?
(A) $A \to C$ $C \to D$
(B) $AB \to C$ $C \to D$
(C) $B \to C$ $C \to D$
(D) $AB \to C$ $AB \to D$

19. Consider the following functional dependencies:
$R(ABCD)$
$AB \to C$
$C \to A$
$D \to B$
$AB \to D$
What are the keys possible for Relation R?
(A) AC, BD, CD (B) AB, BC, CD
(C) AB, AD, BC, CD (D) AC, BC, BD

20. Sailor (Sid, Sname, Rating, age)
Reserves (Sid, bid)
Boats (bid, bname, color)
To select the names of sailors who have reserved all the boats, which Relational algebra operation is used specifically, to do the under lined part?
(A) OUTER JOIN (B) UNION
(C) DIVISION (D) EXCEPT

21. Student1 (RNo, Name, CNo, CName)
Student2 (RNo, Name, CNo, CName)
I. $\pi_{\text{Name}}\,(\sigma_{\text{CNO} = \text{'}C2\text{'}}$ (student1 – student2))
II. $\pi_{\text{Name}}\,(\sigma_{\text{CNO} = \text{'}C2\text{'}}$ (student2 – student1))
Which of the following is TRUE in most of the cases about Number of tuples appear in the result of I and II?
(A) I ≠ II (B) I < II
(C) I > II (D) I = II

22. Consider the following:
I. $\{P / \exists\, S \in$ student $\exists\, D \in$ Department (S.RNo = D.RNo. ∧ D. DNo. = 5 ∧ P.Sname = S.Sname)

II. $\{< S_N > / \exists\ S_R, S_N\ (< S_R, S_N > \in \text{student} \wedge \exists\ D_R, D_N\ (< D_R, D_N > \in \text{Department} \wedge S_R = D_R\ D_N = 5))\}$

Which of the following is TRUE about given expressions?

(A) I – Tuple Relational Calculus
II – Relational algebra

(B) I – Tuple Relational Calculus
II – Domain Relational Calculus

(C) I – Domain Relational Calculus
II – Tuple Relational Calculus

(D) I – Relational Algebra
II – Domain Relational Calculus

23. Consider 2 Relations *R* and *S*, If we want to Retrieve all the tuples from both *R* and *S* without losing any tuple, which Relational Algebra operator is used?

(A) NATURAL JOIN
(B) LEFT OUTER JOIN
(C) INNER JOIN
(D) FULL OUTER JOIN

24. Assume that table *A* has 5 columns, table *B* has 4 columns, one column is common in both the tables. What is the number of columns appear in the result of NATURAL JOIN, LEFT OUTER JOIN, FULL OUTER JOIN respectively?

(A) 8, 9, 9 (B) 8, 8, 9
(C) 8, 8, 8 (D) 8, 9, 8

25. Consider the following Query in English:

"Retrieve the names of students who scored more than 90% but whose age is not more than 15?"

Which Relational operator is compulsory in SQL?

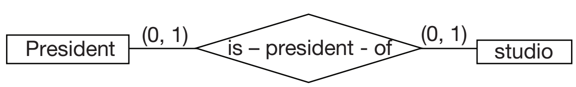
(A) INTERSECTION (B) NATURAL JOIN
(C) OUTER JOIN (D) SET-DIFFERENCE

Answer Keys

1. B	**2.** C	**3.** A	**4.** C	**5.** D	**6.** D	**7.** D	**8.** B	**9.** A	**10.** C
11. A	**12.** A	**13.** B	**14.** B	**15.** C	**16.** C	**17.** C	**18.** B	**19.** C	**20.** C
21. A	**22.** B	**23.** D	**24.** C	**25.** D					

Hints and Explanations

1.



Choice (B)

2. "*" may be used as maximum if there is no limit (0, *) means no restriction at all (general relationship)

– "A movie award goes exactly to one movie" (1, 1)
– A movie may be awarded multiple awards but may be none at all (0, *). Choice (C)

3. The correct match is I – R, II – P, III – Q.
Choice (A)

4. – If we insert some value which already exists, under primary key column, key constraint is violated.
– If we insert NULL value under primary key column Entity Integrity constraint is violated.
– If we insert some value which already exists under the column 'SSNO' which is declared as UNIQUE in the schema, UNIQUE constraint is violated.
Choice (C)

5. All violations are possible with updation operation. Refer above solution. Choice (D)

6. The query will be
SELECT Subject, MAX(Marks)
FROM Student
GROUPBY Subject Choice (D)

7. LOCATE is NOT a Relational algebra operator.
Choice (D)

8. It is a wild card symbol that requests inclusion of all attributes. Choice (B)

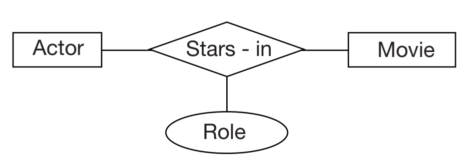
9. $A \to B$
$C \to B$
$D \to B$

L	M	R
ACD		B

$(ACD)^+ = \{ACDB\}$ Prime Attributes = ACD
Non prime Attributes = B
$A \to B$
$\downarrow$ Non prime Attribute
Partial Key
It violates 2NF.
$\therefore$ The Relation is in 1 NF. Choice (A)

10. If All attributes are prime attributes, then a Relation *R* is in minimum 3 NF. Choice (C)

11.



Describes the fact that a Role is stored for every pair of actor 'X' and 'Y' such that X starred in Y. Choice (A)

12. One instructor teaches many courses (0, ∗). Each course is run by exactly one Instructor (1, 1).
Choice (A)

13. $A \to B$
$B \to C$
$BC \to A$
$A \to D$
$E \to A$
$D \to E$

L	M	R
	ABCD E	

$A^+ = \{ABCDE\}$
$B^+ = \{BCADE\}$
$C^+ = \{C\}$
$D^+ = \{DEABC\}$
$E^+ = \{EABCD\}$
∴ 'C' is not the key. Choice (B)

14.

L	M	R
C	ABD	E

$C^+ = \{C\}\ x$
$CA^+ = \{CA\}$
$CB^+ = \{CB\}$
$CD^+ = \{CDABE\}$
Candidate key = CD Choice (B)

15.
R S

A	B
2	3
2	4
4	5

B	C
3	6
5	7
8	9

R NATURAL OUTER JOIN S

A	B	C
2	3	6
2	4	NULL
4	5	7
NULL	8	9

∴ 4-Tuples appear in the Result. Choice (C)

16. Minimum, for every entity one table is required. Since there are 3 entities A, B, C, we need minimum 3 tables.
Choice (C)

17. Both queries will correctly give the desired set of Employee Ids. Choice (C)

18. $AB \to C$
$C \to D$
$AB \to D$
Minimal cover:
$AB \to C$
$C \to D$ Choice (B)

19. $AB \to C$
$C \to A$
$D \to B$
$AB \to D$

L	M	R
	ABCD	

$A^+ = \{A\}$
$B^+ = \{B\}$
$C^+ = \{CA\}$
$D^+ = \{DB\}$
$AB^+ = \{ABCD\}$
$AC^+ = \{AC\}$
$AD^+ = \{ADBC\}$
$BC^+ = \{BCAD\}$
$BD^+ = \{BD\}$
$CD^+ = \{CDAB\}$
Keys are AB, AD, BC, CD. Choice (C)

20. If an SQL query contains "Select – all" term, DIVISION operation is used. Choice (C)

21. (Student1 – Student2) ≠ (Student2 – Student1) option (B) and option (C) depends on the number of tuples in first specified Relation. Choice (A)

22. Both Queries return the names of students Whose department number is 5.
I – Tuple Relational Calculus
II – Domain Relational Calculus Choice (B)

23. FULL OUER JOIN returns all the tuples of Both the tables. Choice (D)

24. Table A has 5 columns
Table B has 4 columns
One column is common to both the tables. In the Result of NATURAL JOIN, LEFT OUTER JOIN, FULL OUTER JOIN, duplicate columns are not allowed, (5 columns + 3 columns) = 8 columns. Choice (C)

25. The query will be as follows
SELECT name
FROM student
WHERE marks > 90
SET DIFFERENCE
SELECT name
FROM student
WHERE age > 15. Choice (D)

Chapter 1

Finite Automata and Regular Languages

LEARNING OBJECTIVES

- Fundamentals
- Languages
- Operations
- Finite state machine
- NFA with ε-moves
- Conversion of NFA to DFA
- Minimization of DFA
- Equivalence between NFA and DFA
- Mealy and Moore machines
- Equivalence of Moore and Mealy machine
- Regular languages
- Constructing FA for given RE
- Pumping lemma for regular sets
- Closure properties of regular sets
- Regular grammar

FUNDAMENTALS

Alphabet: An alphabet is a finite non-empty set of symbols.

Example: Portion of a calculator: {0, 1, 2, 3 … 9, ÷, =, –, +, ×, (,)}

Note: 1. At least one symbol is necessary.

2. 'Σ' denote Alphabet.

String: A string over an alphabet '*A*' is a finite ordered sequence of symbols from '*A*'. The length of string is number of symbols in string, with repetitions counted.

Example: If Σ = {0 – 9, ÷, =, –, +, × (,)} then Strings valid: 12 + 34, 90 × 10, (1 + 2) × (1 ÷ 3)

Strings Invalid: sin (45), log (10) etc. These strings are not valid because sin ( ), log ( ) are not defined over the alphabet set.

Note: Repetitions are allowed.
Length of |12 + 34| = 5(1, 2, +, 3, 4)

- The Empty string denoted by 'ε', is the (unique) string of length zero.

Note: Empty string, $\varepsilon \neq$ empty set, $\varnothing$.

- If S and T are sets of strings, then $ST = \{xy | x \in S \text{ and } y \in T\}$

Given an alphabet A,

$A^o = \{\varepsilon\}$

$A^{n+1} = A.A^n$

…

$$A^* = \bigcup_{n=0}^{\infty} A^n$$

Languages

- A language 'L' over Σ is any finite or infinite set of strings over Σ.
- The elements in L are strings – finite sequences of symbols.
- A language which does not contain any elements is called 'empty language'.

Note: Empty language, { } ≠ {ε}, empty string because { } = $\varnothing \neq \varepsilon$ i.e., Empty language resembles empty set i.e., $\varnothing$.

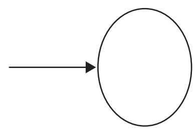
- A language L over an alphabet A is subset of A^* i.e., $L \subset A^*$.

Example 1: Language (L) for strings that consists of only 0's or only 1's and have an odd length over alphabet {0, 1} is

(A) {0, 1, 00, 11, 000, 111 …}
(B) {00, 11, 01, 10 …}
(C) {000, 101, 110, 111 …}
(D) {0, 1, 000, 111, 11111, 00000 …}

Solution: (D)
Only 0's → should have only 0's. It should not be combination of 0's and 1's.
Only 1's → should have only 1's. It should not be combination of 0's and 1's.
Odd length → only odd number of 0's or odd number of 1's i.e., length of string should be odd.

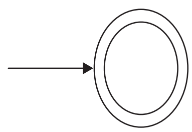
An Empty Languages An empty language is a language which does not accept any strings includinge. The Finite automata for empty language can be represented as



(i.e., One state, non-accepting and no transitions).

A language which only accepts (ε)

E: The language which only accepts 'ε' can be represented as



This machine accepts E – only.

Σ^***:** The set of all strings over an alphabet Σ will be denoted by Σ^*.

Σ^+: This will denote the set $\Sigma^* - \{\varepsilon\}$.

Ex: If $\Sigma = \{0, 1\}$ then

$\Sigma^* = \{\varepsilon, 0, 1, 00, 01, 10, 11, 000, 001, \ldots\}$

$\Sigma^+ = \{0, 1, 00, 01, 10, 11, 000, 001,\}$

Operations

Operations on strings

1. **Concatenation:** Combines two strings by putting one after other.

Example 2: Two strings are defined as x = java, y = script. The concatenation ($x.y$) of two strings results in ________.

(A) scriptjava (B) javascript
(C) jascriptva (D) scrijavapt

Solution: (B)

$x.y$ = java.script = javascript

Note: Concatenation of empty string with any other string gives string itself.

i.e., $x.\varepsilon = \varepsilon.x = x$

2. **Substring:** If 'w' is a string, then 'v' is a substring of 'w' if there exists string x and y such that $w = xvy$.

'x' is called 'prefix' and y is called suffix of w.

Example 3: String, w = 'gymnastics' is defined with prefix, x = '*gym*' and suffix, y = '*cs*'. The substring of the given string is ________

(A) nasti (B) mnas
(C) gymnastics (D) ics

Solution: (A)

Because, $w = xvy$

$\Rightarrow$ gymnastics = gymvcs

$\therefore v$ = nasti

3. **Kleen star operation:** Let 'w' be a string, w^* is set of strings obtained by applying any number of concatenations of w with itself, including empty string.

Example: $a^* = \{\varepsilon, a, aa, aaa, \ldots\}$

4. **Reversal:** If 'w' is a string, then w^R is reversal of string spelled backwards.

Rules:

- $x = (x^R)^R$
- $(xz)^R = z^R \cdot x^R$

Example 4: A string, x is defined as, x = butter. Then $(x^R)^R$ is ________

(A) butter (B) rettub
(C) butret (D) retbut

Solution: (A)

$x \longrightarrow$ butter

$x^R \longrightarrow$ rettub

$(x^R)^R \longrightarrow$ butter.

Operations on languages

1. **Union:** Given some alphabet Σ, for any two languages, L_1, L_2 over Σ, the union $L_1 \cup L_2$ of L_1 and L_2 is the language, $L_1 \cup L_2 = \{w \in \Sigma^* | w \in L_1 \text{ or } w \in L_2\}$
2. **Intersection:** Given some alphabet Σ, for any two languages L_1, L_2 over Σ, the intersection $L_1 \cap L_2$ of L_1 and L_2 is language, $L_1 \cap L_1 = \{w \in \Sigma^* | w \in L_1 \text{ and } w \in L_2\}$
3. **Difference:** Given some alphabet Σ, for any two languages L_1, L_2 over Σ, the difference $L_1 - L_2$ of L_1 and L_2 is language, $L_1 - L_2 = \{w \in \Sigma^* | w \in L_1 \text{ and } w \notin L_2\}$

Note: Difference is also called 'Relative Complement.'

A special case of difference is obtained when $L_1 = \Sigma^*$, in which case. Complement $\overline{L}$ of language, L is defined as, $\overline{L} = \{w \in \Sigma^* | \, w \notin L\}$

4. **Concatenation:** Given an alphabet Σ, for any two languages L_1, L_2 over Σ, the concatenation $L_1 \, L_2$ of L_1 and L_2 is language

$L_1L_2 = \{w \in \Sigma^* | \exists \, u \in L_1, \exists \, v \in L_2, w = uv\}$

Properties:

$L\varnothing = \varnothing = \varnothing L$

$L\,\{\varepsilon\} = L = \{\varepsilon\}$ L

$(L_1 \cup \{\varepsilon\})L_2 = L_1L_2 \cup L_2$

$L_1\,(L_2 \cup \{\varepsilon\}) = L_1L_2 \cup L_1$

$L^n\,L = LL^n = L^{n+1}$

Note: $L_1L_2 \neq L_2L_1$

Example 5: Let $L_1 = \{00, 11\}$, $L_2 = \{01, 10\}$. Then $L_1 o L_2$ = ________

(A) {00, 11, 01, 10}
(B) {0001, 0010, 1101, 1110}
(C) {0001, 0010, 11, 01, 10}
(D) {00, 1101, 1110, 11, 10}

Solution: (B)

$L_1 o L_2 = \{00, 11\} \text{ o } \{01, 10\} = \{00.01, 00.10, 11.01, 11.10\} = \{0001, 0010, 1101, 1110\}$

5. **Kleen * closure (L*):** Given an alphabet Σ, for any language L over Σ, the * closure L^* of L is language,

$L^* = U_{n \geq 0} L^n$

6. **Kleen + closure (L^+):** The kleen +closure, L^+ of L is the language, $L^+ = U_{n\geq 1} L^n$

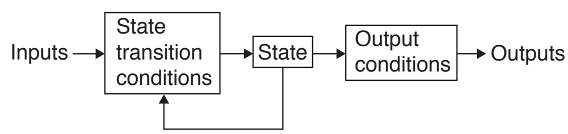
$L^* = L^0 \cup L^1 \cup L^2 \cup \ldots L^n \cup \ldots$
$L^+ = L^1 \cup L^2 \cup L^3 \ldots \cup L^n \cup \ldots$

Properties:

$\varnothing^* = \{\varepsilon\}$
$L^+ = L^*L$
$(L^*)^* = L^*$
$L^*\, L^* = L^*$

Finite State Machine (FSM)

- FSM is simplest computational model of limited memory computers.
- FSM is designed to solve decision problems i.e., to decide whether given input satisfies certain conditions.
- The next state and output of a FSM is a function of input and of current state.

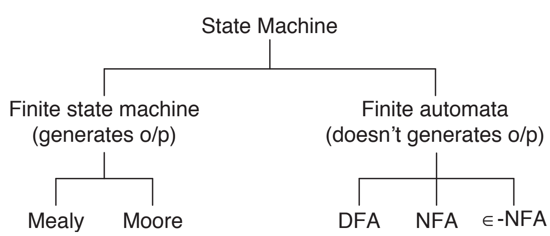


Types of FSM:

1. Melay machine.
2. Moore machine

Finite Automata (FA):

- FA is a state machine that comprehensively captures all possible states and transitions that a machine can take while responding to a stream (sequence) of input symbols.
- FA is recognizer of 'regular languages'.



Types of FA

1. Deterministic Finite Automata (DFA):

- DFA machine can exists in only one state at any given time.
- DFA is defined by 5-tuple: $\{Q, \Sigma, q_0, F, \delta\}$, where

$Q \rightarrow$ Finite number of states (elements)
$\Sigma \rightarrow$ Finite set of symbols (alphabets)
$q_o \rightarrow$ Start/Initial state
$F \rightarrow$ Set of final states.
$\delta \rightarrow$ Transition function, which is a mapping between

$$\delta: Q \times \Sigma \rightarrow Q.$$

How to use DFA:

Input: A word w in Σ^*
Question: Is w acceptable by DFA?

Steps:

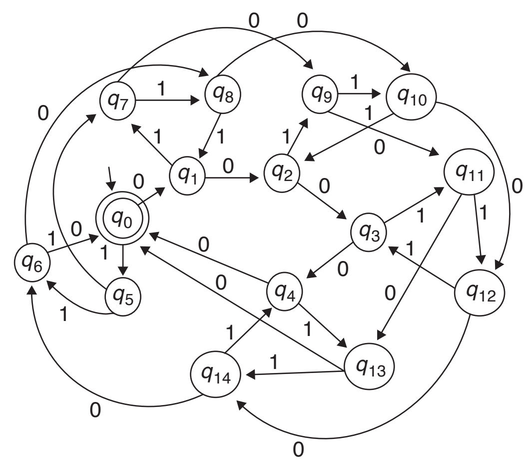
- Start at 'initial state', q_o.
- For every input symbol in sequence w, do.
- Compute the next state from current state, given the current input symbol in w and transition function.
- If after all symbols in 'w' are consumed, the current state is one of the final states (f) then accept 'w';
- Otherwise, reject w.

Transition diagram: State machines are represented by directed graphs called transition (state) diagrams.

- The vertices denoted by single circle represent the state and arcs labeled with input symbol correspond to transition.
- The final states are represented with double circles.

Transition Table: Transition function can be represented by tables.

Example 6: The following finite state machine accepts all those binary strings in which the numbers of 0's and 1's are respectively.



(A) Divisible by 3 and 2
(B) Odd and even
(C) Divisible by 5 and 3
(D) Divisible by 2 and 3

Solution: (C)
Number of 0's is divisible by 5.
Number of 1's is divisible by 3.

Table *Transition Table*

Current State	0	1
$\rightarrow q_0$	q_1	q_5
q_1	q_2	q_7
q_2	q_3	q_9
q_3	q_4	q_{11}
q_4	q_0	q_{13}
q_5	q_7	q_6
q_6	q_8	q_0
q_7	q_9	q_8
q_8	q_{10}	q_1

q_9	q_{11}	q_{10}
q_{10}	q_{12}	q_2
q_{11}	q_{13}	q_{12}
q_{12}	q_{14}	q_3
q_{13}	q_0	q_{14}
q_{14}	q_6	q_4

Note: Minimum number of states for k-divisibility is k-states.
In above example, $q_0 - q_{14} \to 15$ – states.
$\therefore \quad 5 \times 3 = 15$
The given binary strings have number of 0's divisible by 5 and number of 1's divisible by 3.

2. Non-deterministic finite Automata (NFA):

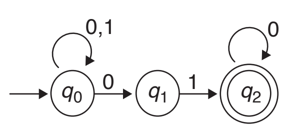
- The machine can exist in multiple states at the same time.
- Each transition function maps to a set of states.
- NFA is defined by 5-tuple: $\{Q, \Sigma, q_0, F, \delta\}$, where

$Q \to$ Finite number of states (elements)
$\Sigma \to$ Finite set of symbols. (Alphabets)
$q_o \to$ Start/Initial state
$F \to$ Set of final states.
$\delta \to$ Transition function which is a mapping between
$\delta = Q \times \Sigma \to 2^Q$

How to use NFA:
Input: a word w in Σ^*
Question: Is w accepted by NFA?
Steps:

- Start at 'start state' q_0.
- For every input symbol in the sequence, *w* does.
- Determine all possible next states from current state, given the current input symbol in *w* and transition function.
- If after all symbols in *w* are consumed, at least one of the current states is a final state then accept *w*.
- Otherwise, reject *w*.

Example 7: What is the language, *L* generated by the below NFA, given strings defined over alphabet, $\Sigma = \{0, 1\}$.



(A) Strings that end with '0'
(B) Strings that start with '0' and end with '0'
(C) Strings that contain '01' as substring
(D) Strings that contain '01' as substring and end with '0'

Solution: (D)

State	0	1
$\to q_0$	$\{q_0, q_1\}$	$\{q_0\}$
q_1	$\varnothing$	q_2
q_2	$\{q_2\}$	$\varnothing$

String: 0100100

$$q_0 \xrightarrow{0} \{q_0, q_1\}$$
$$q_0 \xrightarrow{0} q_0 \xrightarrow{1} q_0 \xrightarrow{0} \{q_0, q_1\}$$
$$q_0 \xrightarrow{0} q_0 \xrightarrow{1} q_0 \xrightarrow{0} q_0 \xrightarrow{0} \{q_0, q_1\}$$
$$\xrightarrow{q_0 1} q_0 \xrightarrow{0} q_0 \xrightarrow{0} \{q_0, q_1\} \text{ (Non-deterministic)}$$
$$q_0 \xrightarrow{0} q_0 \xrightarrow{1} q_0 \xrightarrow{0} q_0 \xrightarrow{0} \{q_0, q_1\}$$
$$q_1 \xrightarrow{1} q_2 \xrightarrow{0} q_2 \xrightarrow{0} q_2$$

Table 2 *Difference between NFA and DFA*

DFA	NFA
1. All transitions are deterministic i.e., each transition leads to exactly one state.	1. Transitions could be non-deterministic i.e., a transition could lead to a subset of states.
2. For each state, the transition on all possible symbols should be defined.	2. For each state, not all symbols necessarily have to be defined.
3. Accepts input if last state is in 'F'.	3. Accepts input if one of last states is in 'F'.
4. Practical implementation is feasible.	4. Practical implementation has to be deterministic (so needs conversion to DFA).

Relation between DFA and NFA

- A language '*L*' is accepted by a DFA if and only if it is accepted by a NFA.
- Every DFA is special case of a NFA.

Example 8: Let N_f and D_f denote the classes of languages accepted by non-deterministic finite automata and deterministic finite automata respectively. Which one of following is true?

(A) $D_f \subset N_f$ (B) $D_f \supset N_f$
(C) $D_f = N_f$ (D) $D_f \in N_f$

Solution: (C)
According to 'subset construction', every language accepted by NFA is also accepted by some DFA.
$\therefore \quad D_f = N_f$

NFA WITH $\in$-MOVES

- $\in$-transitions in finite automata allows a state to jump to another state without consuming any input symbol.

Conversion and Equivalence:

$\in$-NFA $\to$ NFA $\to$ DFA

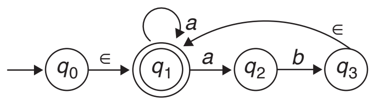
NFA without $\in$-moves:

- Two FA, $N_\in$ and N are said to be equivalent, if $L(N_\in) = L(N)$ i.e., any language described by some $N_\in$, there is an N that accepts the same language.
- For $N_\in = (Q, Z, \delta, q_0, F)$ and $N = (Q, \Sigma', \delta', q_0, F')$, Find
- $\delta'(q, a) = \in$-closure $(\delta(\in\text{-closure}(q), a))$

- $F' = \{F \cup \{q_0\}\}$, if $\in$-closure (q_0) contains a member of $F = F$, otherwise.

Note: When transforming $N_\in$ to N, only transitions are required to be changed and states remains same.

Example 9: Consider following NFA with $\in$-moves.



If given NFA is converted to NFA without $\in$-moves, which of following denotes set of final states?

(A) $\{q_0, q_1\}$ (B) $\{q_1, q_2\}$
(C) $\{q_1, q_2, q_3\}$ (D) $\{q_1\}$

Solution: Let $N = (Q, \Sigma^1, \delta^1, q_0, F^1)$
$F^1 = F \cup \{q_0\}$
ε-closure $(q_0) = \{q_0, q_1\}$
$\therefore F^1 = \{q_1\} \cup \{q_0, q_1\} = \{q_0, q_1\}$
Conversion $N_\in \rightarrow N$:
To compute, δ^1
$\in$-closure $(q_0) = \{q_0, q_1\}$, $\in$-closure $(q_3) = \{q_3, q_1\}$
$\delta^1(q_0, a) = \{q_1, q_2\}$, $\delta^1(q_0, b) = \varnothing$, $\delta^1(q_2, a) = \varnothing$.
$\delta^1(q_1, a) = \{q_1, q_2\}$, $\delta^1(q_1, b) = \varnothing$, $\delta^1(q_2, b) = \{q_1, q_3\}$
$\delta^1(q_3, a) = \{q_1, q_2\}$, $\delta^1(q_3, b) = \varnothing$

Table 3 *Transition Table*

State \ Input	a	b
$\rightarrow q_0$	$\{q_1, q_2\}$	$\varnothing$
q_1	$\{q_1, q_2\}$	$\varnothing$
q_2	$\varnothing$	$\{q_1, q_3\}$
q_3	$\{q_1, q_2\}$	$\varnothing$

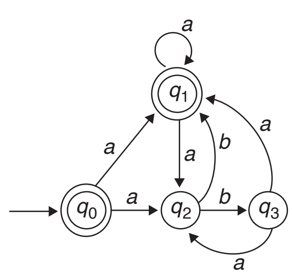


Figure 1 Transition diagram

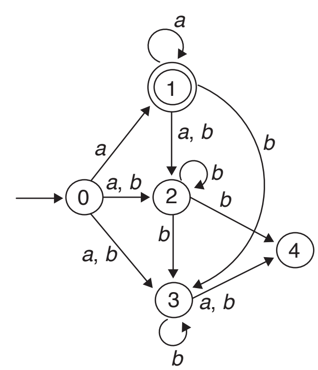
Conversion of NFA to DFA

Let a NFA be defined as, $N = (Q_N, \Sigma, \delta_N, q_0, F_N)$
The equivalent DFA, $D = (Q_D, \Sigma, \delta_D, q_0, F_D)$ where:
Step I: $Q_D = 2^{Q_N}$; i.e., Q_D is set of all subsets of Q_N i.e., it is power set of Q_N.
Step II: F_D is set of subsets S of Q_N such that $S \cap F_N \neq \varnothing$. i.e., F_D is all sets of N's states that include atleast one accepting state of N.
Step III: For each set, $S \leq Q_N$ and for each input symbol a in Σ: $\delta_D(S, a) = \cup_{P \in S} \delta_N(P, a)$

That is, to compute $\delta_D(S, a)$, look at all states P in S, see what states N goes to starting from P on input a, and take the union of all those states.

Note: For any NFA, N with 'n' states, the corresponding DFA, D can have 2^n states.

Example 10: What is the number of final states in DFA constructed from the given NFA?



(A) 1 (B) 2
(C) 3 (D) 4

Solution:

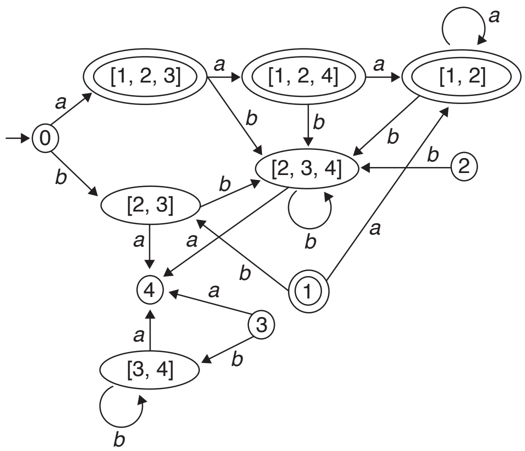
Table 4 *Transition Table of NFA*

State \ Input	a	b
$\rightarrow 0$	{1, 2, 3}	{2, 3}
1	{1, 2}	{2, 3}
2	$\varnothing$	{2, 3, 4}
3	{4}	{3, 4}
4	$\varnothing$	$\varnothing$

Table 5 *Transition Table of DFA*

State \ Input	a	b
$\rightarrow$0	[1, 2, 3]	[2, 3]
1	[1, 2]	[2, 3]
2	$\varnothing$	[2, 3, 4]
3	4	[3, 4]
4	$\varnothing$	$\varnothing$
[1, 2]	[1, 2]	[2, 3, 4]
[2, 3]	[4]	[2, 3, 4]
[3, 4]	[4]	[3, 4]
[1, 2, 3]	[1, 2, 4]	[2, 3, 4]
[1, 2, 4]	[1, 2]	[2, 3, 4]
[2, 3, 4]	[4]	[2, 3, 4]

Hence final states in obtained DFA is '4'.
DFA is: Choice (D)

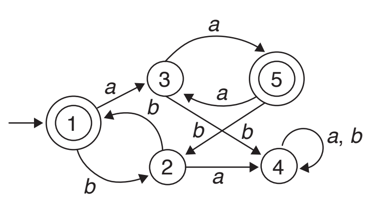


Minimization of DFA

Given a DFA, $M = (Q, \Sigma, \delta, q_0, F)$, we construct a reduced DFA, $M' = (Q', \Sigma', \delta', q'_0, F')$ as follows

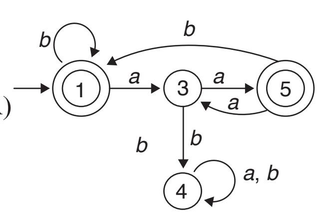
1. Remove all inaccessible states. All states that are unreachable from the initial state are removed.
2. Consider all pairs of states (p, q), If $p \in F$ and $q \in F$ or vice versa mark the pair (p, q) as distinguishable.
3. Repeat until no previously unmarked pairs are marked. For all pairs (p, q) and all $a \in \Sigma$, compute $\delta(p, a) = p_a$ and $\delta(p, q) = q_a$. If the pair (p_a, q_a) is marked as distinguishable mark (p, q) as distinguishable.
4. Find the sets of all indistinguishable states, say $\{q_i, q_j, \cdots q_k\}$, $\{q_\ell, q_m, \cdots q_n\}$, etc. For each set $\{q_i, q_j, \ldots q_k\}$ of such indistinguishable states, create a state labelled $ij \ldots k$ for M.
5. For each transition rule of M of the from $\delta(q_r, q) = q_p$, find the sets to which q_r and q_p belong. If $q_r \in \{q_i, q_j, \ldots q_k\}$ and $q_p \varepsilon \{q_\ell, q_m, \cdots q_n\}$, add a rule to δ: $\delta'(ij \ldots k, a) = \ell m \ldots n$.

Example 11: A DFA with alphabet $\Sigma = \{a, b\}$ is given below:

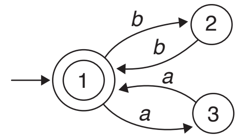


Which of the following is valid minimal DFA which accepts same language as given DFA?

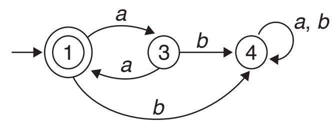
(A)



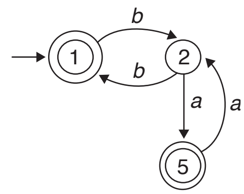
(B)



(C)



(D)



Solution: (B)

Initially, $\{1, 5\}$, $\{2, 3, 4\}$

Depending on next states and inputs, the partitions of states can be as: $\{\{1, 5\}, \{2\}, \{3\}, \text{and } \{4\}\}$

Since, 1 to 5 have same transition, unite $\{1, 5\}$

State 4 is dead state $\to$ It has transition only to itself. Since, $\{2\}$, $\{3\}$ are singletons, they exist.

$\therefore$ States in minimized DFA are $\{1, 2, \text{and } 3\}$

$\{1\} \to \{1, 5\}$

For transitions, since $1 \xrightarrow{a} 3$, $1 \xrightarrow{b} 2$ in given DFA, in minimized DFA, transitions are added from $1 \xrightarrow{a} 3$, $1 \xrightarrow{b} 2$. Also, since $2 \xrightarrow{b} 1$, $3 \xrightarrow{a} 1$ in given DFA, the minimized DFA, transitions are added from $2 \xrightarrow{b} 1$, $3 \xrightarrow{a} 1$.

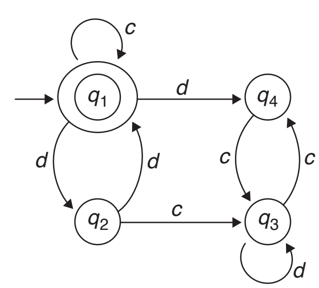
Equivalence Between NFA and DFA

There is a DFA_D for any NFA_N i.e., $L(D) = L(N)$.

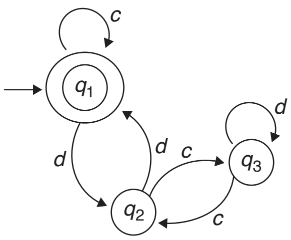
Construction:

- In DFA or NFA, whenever an arrow is followed, there is a set of possible states. This set of states is a subset of Q.
- Track the information about subsets of states that can be reached from initial state after following arrows.
- Consider each subset of states of NFA as a state of DFA and every subset of states containing a final state as a final state of DFA.

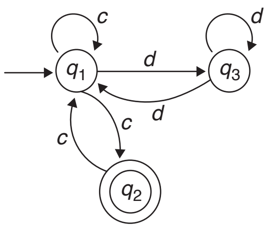
Example 12: Which of following is equivalent DFA for the NFA given below:



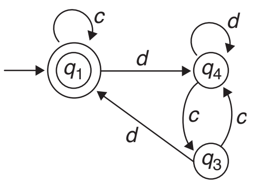
(A)



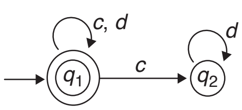
(B)



(C)



(D)



Solution: (A)

Table 6 *Transition Table of NFA*

δ	***c***	***d***
$\rightarrow q_1$	q_1	$\{q_2, q_4\}$
q_2	q_3	q_1
q_3	q_4	q_3
q_4	q_3	$\varnothing$

Table 7 *Transition Table of DFA*

δ	***c***	***d***
$\rightarrow q_1$	q_1	q_2
q_2	q_3	q_1
q_3	q_2	q_1

Table 8 *Common Table*

δ	***c***	***d***
(q_1, q_1)	(q_1, q_1)	(q_2, q_4, q_2)
(q_2, q_2)	(q_3, q_3)	(q_1, q_1)
(q_3, q_3)	(q_4, q_2)	(q_3, q_3)
(q_4)	q_3	$\varnothing$

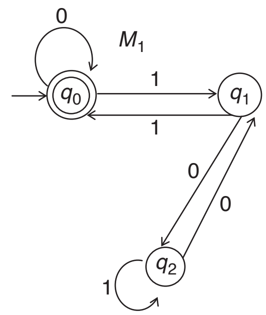
Equivalence of Finite Automatas:

- Two automatas A and B are said to be equivalent if both accept exactly the same set of input strings.
- If two automatas M_1 and M_2 are equivalent then

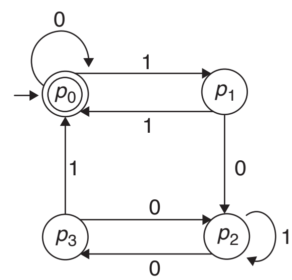
(i) If there is a path from the start state of M_1 to a final state of M_1 labeled $a_1a_2 \ldots a_k$ then there is a path from the start state of M_2 to the final state of M_2 labeled $a_1a_2\ldots a_k$.

(ii) If there is a path from the start state of M_2 to a final state M_2 labeled $b_1b_2 \ldots b_i$ then there is a path from the start state of M_1 to the final state of M_1 labeled $b_1b_2 \ldots b_i$.

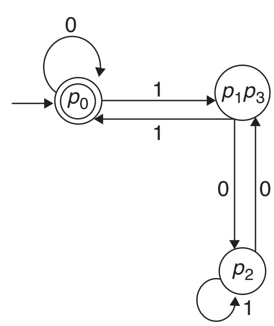
Example:



M_2:



In M_2, states p_1 and p_3 are equivalent (as both are reaching either final or non-final states with same input). After minimizing M_2, we will get



$\therefore$ M_1 and M_2 are equivalent.

Union: The union of two languages L and M is the set of strings that are in both L and M.

Ex: $L = \{0, 1\}$, $M = \{111\}$

$L\ U\ M = \{0, 1{,}111\}$.

Concatenation: The concatenation of Languages L and M is the set of strings that can be formed by taking any string in L and concatenating it with any string in M.

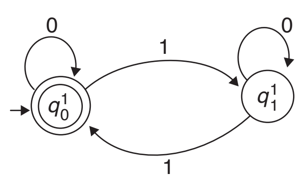
Example: $L = \{0, 1\}$, $M = \{\varepsilon, 010\}$

$LM = \{0, 1, 0010, 1010\}$.

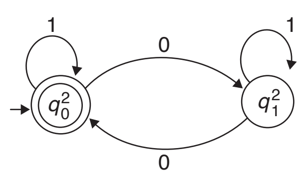
Closure, Star or Kleen star of a language L:
Kleen star is denoted as L^*. It represents the set of strings that can be formed by taking any number of strings from L with repetition and concatenating them. It is a Unary operator.
L^0 is the set; we can make selecting zero strings from L.
$L^0 = \{\varepsilon\}$
L^1 is the language consisting of selecting one string from L.
L^2 is the language consisting of concatenations selecting two strings from L.
…
L^* is the union of L^0, L^1 , …L^∞.
Ex: $L = \{0,10\}$
$L^* = \{0,00,000,10,010, \ldots\}$

Intersection:
Let two DFAs M_1 and M_2 accept the languages L_1 and L_2.
$M_1 = (Q_1, \Sigma, \delta_1, q_0^1, .F_1)$
$M_2 = (Q_2, \Sigma, \delta_2, q_0^2, F_2)$
The intersection of M_1 and M_2 can be given as
$M = (Q_1, \Sigma, \delta, q_0\ F)$
Q = Pairs of states, one from M_1 and one from M_2 i.e.,
$Q = \{(q_1, q_2) \mid q_1 \in Q_1 \text{ and } q_2 \in Q_2\}$
$Q = Q_1 \times Q_2$.
$q_0 = (q_0^1, q_0^2)$
$\delta\ (q_i^1\ q_j^2), x) = (\delta_1(q_1^1, x), \delta_2(q_j^2, x))$
$F = \{(q_1, q_2) \mid q_1, \in F_1 \text{ and } q_2 \in F_2\}$

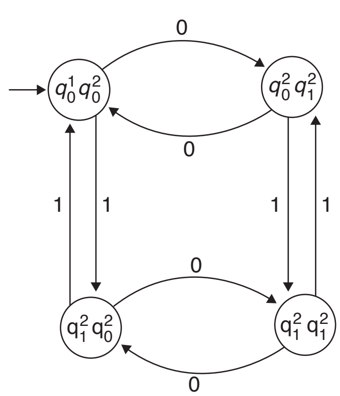
Example:
M_1: Strings with even number of 1's.



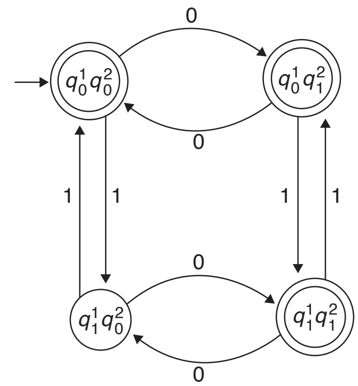
M_2: Strings with odd number of 0's.



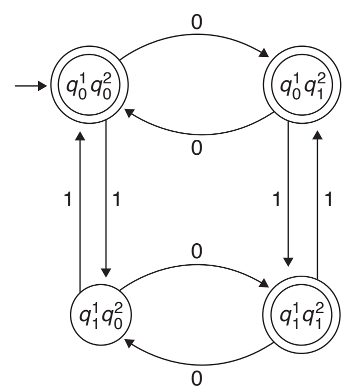
$M_1 \cap M_2$: Strings with even number of 1's and odd number of 0's.



Union of M_1 and M_2:



Difference: The difference of L_1 and L_2 can be given as $L_1 - L_2$ with $M = (Q, \Sigma, \delta, q_0, F)$.
$Q = Q_1 \times Q_2$
$q_0 = (q_0^{\ 1}, q_0^{\ 2})$
$\delta((q_i^{\ 1}, q_j^{\ 2}), x) = (\delta_1\ (q_i^{\ 1}, x), \delta_2(q_j^{\ 2}, x))$
$F = \{(q_1, q_2) \mid q_1, \in F_1 \text{ and } q_2 \notin F_2\}$



Reversing a DFA:

- M is a DFA which recognizes the language L.
- M^R will accept the language L^R.

To construct M^R:

- Reverse all transitions
- Turn the start state to final state
- Turn the final states to start state.
- Merge states and modify the FA,

such that the resultant contain a single start state.

Mealy and Moore Machines

Moore Machine

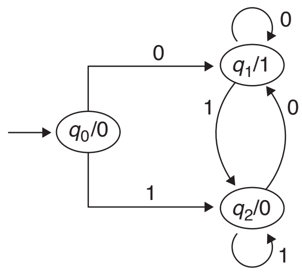
A moore machine is a finite state machine, where outputs are determined by current state alone.

A Moore machine associates an output symbol with each state and each time a state is entered, an output is obtained simultaneously. So, first output always occurs as soon as machine starts.

Moore machine is defined by 6-tuples:
$(Q, \Sigma, \delta, q_0, \Delta, \lambda)$, where
$Q \rightarrow$ Finite set of states
$\Sigma \rightarrow$ Finite set of input symbols
$\Delta \rightarrow$ It is an output alphabet
$\delta \rightarrow$ Transition function, $Q \times \Sigma \rightarrow Q$ (state function)
$\lambda \rightarrow$ Output function, $Q \rightarrow \Delta$ (machine function)
$q_0 \rightarrow$ Initial state of machine

Note: The output symbol at a given time depends only on present state of moore machine.

Example 13: The language generated by the following moore machine is:



(A) 2's complement of binary number.
(B) 1's complement of binary number.
(C) Has a substring 101.
(D) Has a substring 110.

Solution: (B)
Binary number: 1011
1's complement: 0100

$$q_0 \xrightarrow{1/0} q_2, \xrightarrow{0/1} q_1 \xrightarrow{1/0} q_2 \xrightarrow{1/0} q_2$$

$1 \rightarrow 0,\ 0 \rightarrow 1,\ 1 \rightarrow 0,\ 1 \rightarrow 0$

Mealy Machine

- A mealy machine is a FSM, where outputs are determined by current state and input.
- It associates an output symbol with each transition and the output depends on current input.
- Mealy machine is defined on 6-tuples: $(Q, \Sigma, \delta, q_0, \Delta, \lambda)$, where

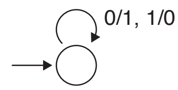
Q – Finite set of states.
Σ – Finite set of input symbols.
δ – $(Q \times \Sigma \rightarrow Q)$ is transition function.
$q_0 \rightarrow q_0 \in Q$ is initial state.
$\Delta \rightarrow$ Finite set of output symbols.
$\lambda \rightarrow$ Output function, $\lambda(Q \rightarrow \Delta)$

Note: In Moore machine, for input string of length n, the output sequence consists of $(n + 1)$ symbols.

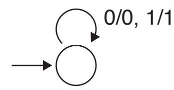
In Mealy machine, for input string of length n, the output sequence also consists of 'n' symbols.

Example 14: Let $(\text{Me})^2$ mean that given a Mealy machine, an input string is processed and then output string is immediately fed into the machine (as input) and reprocessed. Only this second resultant output is considered as the final output of $(\text{Me})^2$. If final output string is same as original input string then $(\text{Me})^2$ has an identity property. Consider following machines.

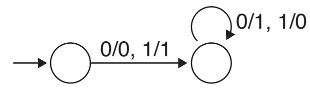
(i)



(ii)



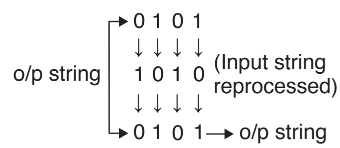
(iii)



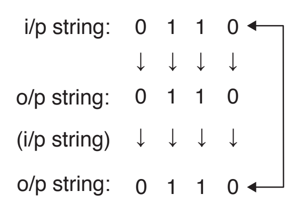
Which of above machines have identity property?
(A) (i) only
(B) (i) and (ii) but not (iii)
(C) (i) and (iii) but not (ii)
(D) All have identity property

Solution: (D)

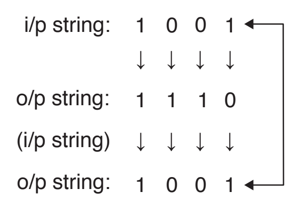
(i) Consider i/p string



(ii)



(iii)



Equivalence of Moore and Mealy machine

(a) Mealy machine equivalent to Moore machine:
If $M_1 = (Q, \Sigma, \Delta, \delta, \lambda, q_0)$ is a Moore machine, then there is a Mealy machine M_2 equivalent to M_1.

Proof: Let $M_2 = (Q, \Sigma, \Delta, \delta, \lambda^1, q_0)$ and define $\lambda^1(q, a)$ to be $\lambda(\delta(q, a))$ for all states q and input symbol 'a'.

Then M_1 and M_2 enter the same sequence of states on the same input, and with each transition M_2 emits the o/p that M_1 associates with the state entered.
Let us consider Mealy Machine

Present State	Next State			
	$a = 0$		$a = 1$	
	Input State	Output	Input State	Output
$\rightarrow q_1$	q_3	0	q_2	0
q_2	q_1	1	q_4	0
q_3	q_2	1	q_1	1
q_4	q_4	1	q_3	0

To convert the Mealy machine to Moore machine,

- We look into the next state column for any state, say q_i and determine the number of different outputs associated with q_i in next column.
- Split q_i into several different states, the number of such states being equal to the number of different outputs associated with q_i.

Present State	Next State			
	$a = 0$		$a = 1$	
	Input State	Output	Input State	Output
$\rightarrow q_1$	q_3	0	q_{20}	0
q_{20}	q_1	1	q_{40}	0
q_{21}	q_1	1	q_{40}	0
q_3	q_{21}	1	q_1	1
q_{40}	q_{41}	1	q_3	0
q_{41}	q_{41}	1	q_3	0

- The pair of states and outputs in the next state column can be rearranged as:

Present state	Next State $a = 0$	Next State $a = 1$	output
$\rightarrow q_1$	q_3	q_{20}	1
q_{20}	q_1	q_{40}	0
q_{21}	q_1	q_{40}	1
q_3	q_{21}	q_1	0
q_{40}	q_{41}	q_3	0
q_{41}	q_{41}	q_3	1

Moore machine equivalent to Mealy machine

Let $M_1 = (Q, \Sigma, \Delta, \delta, \lambda, q_0)$ be a Mealy machine. Then there is a machine M_2 equivalent to M_1

Proof: Let $M_2 = (QX\Delta, \Sigma, \Delta, \delta^1, \lambda^1, [q_0, b_0])$, where b_0 is an arbitrary selected member of Δ.

That is, the states of M_2 are pairs $[q, b]$ consisting of a state of M_1 and output symbol, Define δ^1 $([q, b], a) = [\delta(q, a), \lambda, (q, a)]$ and λ^1 $([q, b]) = b$.

The second component of a state $[q, b]$ of M_2 is the output made by M_1 on some transition into state q.

Only the first components of M_2's states determine the moves made by M_2.

Every induction on 'n' shows that if M_1 enters states $q_0, q_1 \ldots q_n$ on inputs $a_1, a_2 \ldots a_n$ and emits output $b_1, b_2, \ldots b_n$ then M_2 enters states $[q_0, b_0], [q_1, b_1] \ldots [q_n, b_n]$ and emits outputs $b_0, b_1 \ldots b_n$.

Let us consider the Moore machine

Present State	Next State $a = 0$	Next State $a = 1$	Output
$\rightarrow q_0$	q_3	q_1	0
q_1	q_1	q_2	1
q_2	q_2	q_3	0
q_3	q_3	q_0	0

- To convert Moore into Mealy machine, we must follow the reverse procedure of converting Mealy machine into Moore machine.
- For every input symbol we form, the pair consisting of the next state and the corresponding output and reconstruct the table for Mealy machine.
- For example, the state q_3 and q_1 in the next state column should be associated with outputs 0 and 1, respectively.

The Transition table for Mealy machine is:

Present state	Next State			
	$a = 0$		$a = 1$	
	state	output	state	output
$\rightarrow q_0$	q_3	0	q_1	1
q_1	q_1	1	q_2	0
q_2	q_2	0	q_3	0
q_3	q_3	0	q_0	0

Regular Languages

The set of regular languages over an alphabet Σ is defined recursively as below. Any language belonging to this set is a regular language over Σ.

Definition of set of regular languages

- Basis clause: $\varnothing$, $\{\varepsilon\}$, $\{a\}$ for any symbol $a \in \Sigma$, are regular languages.
- Inductive clause: If L_r and L_s are regular languages, then $L_r \cup L_s$, $L_r \cdot L_s$, L_r^* are regular languages.
- External clause: Nothing is a regular language, unless it is obtained from above two clauses.

Regular language: Any language represented by regular expression(s) is called a regular language.

Ex: The regular expression a^* denotes a language which has $\{\varepsilon, a, aa, aaa, \ldots\}$

Regular expression

- Regular expressions are used to denote regular languages.
- The set of regular expressions over an alphabet Σ is defined recursively as below. Any element of that set is a regular expression.

- Basis clause: $\varnothing$, $\in$, a are regular expression corresponding to languages $\varnothing$, $\{\in\}$, $\{a\}$ respectively where a is an element of Σ.
- Inductive clause: If r and s are regular expression corresponding to languages L_r and L_s then $(r + s)$, (rs) and (r^*) are regular expressions corresponding to the languages $L_r \cup L_s$, $L_r \cdot L_s$ and L_r^* respectively.
- External clause: Nothing is a regular expression, unless it is obtained from above two clauses.

Closure property of regular expressions The iteration or closure of a regular expression R, written as R^* is also a regular expression.

Ex: $\Sigma = \{a\}$ then a^* denotes the closure of Σ.

$a^* = \{\varepsilon, a, aa, aaa, \ldots\}$

Conventions on regular expressions

1. The operation '*' has highest precedence over concatenation, which has precedence over union (+).
   i.e., $RE\ (a + (b(c^*))) = a + bc^*$
2. The concatenation of K r's, where r is a regular expression is written as r^k. The language corresponding to r^k is L_r^k. Where L_r is language corresponding to regular expression r i.e., $rr = r^2$
3. r^+ is a regular expression to represent L_r^+

Note: A regular expression is not unique for a language i.e., regular language corresponds to more than one regular expression.

Example 15: Give regular expression for set of strings which either have 'a' followed by some b's or all b's also containing 'ε'.

(A) $b^* + ab^*$ (B) $a^* + ba^*$
(C) $(\varepsilon) + (\varepsilon + a)\ b^+$ (D) $b^* + ab^* + \varepsilon$

Solution: (C)

The regular expression is, $r = ab^+ + b^+ + \varepsilon = b^+(a + \varepsilon) + \varepsilon$.

Identity rules for regular expressions:

1. $\varnothing + R = R$
2. $\varnothing \cdot R = R\varnothing = \varnothing$
3. $\varepsilon R = R\varepsilon = R$
4. $\varnothing^* = \varepsilon$ and $\varepsilon^* = \varepsilon$
5. $R + R = R$
6. $RR^* = R^*\ R = R^+$
7. $\varepsilon + RR^* = R^*$ and $\varepsilon + R^*\ R = R^*$
8. $(R^*)^* = R^*$
9. $R^*\ R^* = R^*$
10. $\varepsilon + R^* = R^*$
11. $(R + \varepsilon)^* = R^*$
12. $R^*(\varepsilon + R)^* = (\varepsilon + R)^*\ R^* = R^*$
13. $R^*\ R + R = R^*\ R$
14. $(P + Q)R = PQ + QR$ and $R(P + Q) = RP + RQ$
15. $(P + Q)^* = (P^*\ Q^*)^* = (P^* + Q^*)^*$
16. $(PQ)^*\ P = P\ (QP)^*$
17. R is given as, $R = Q + RP$ has unique solution, $R = QP^*$. This is Arden's theorem.
18. $(P + Q)^* = (P^* + Q) = (P + Q^*)$

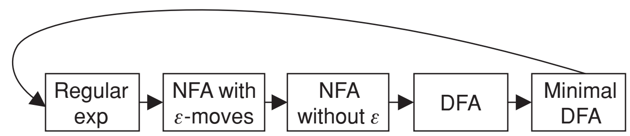
Example 16: If r_1 and r_2 are regular expressions denoting languages L_1 and L_2 respectively then which of following is false?

(A) $(r_1)|\ (r_2)$ is regular expression denoting $L_1 \cup L_2$.
(B) $(r_1)\ (r_2)$ is regular expression denoting $L_1 \cdot L_2$.
(C) $\varnothing$ is not a regular expression.
(D) $\{r_1\}^*$ is regular expression denoting L_1^*.

Solution: (C)

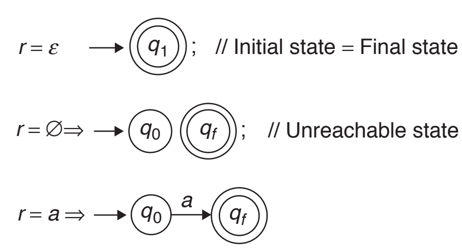
CONSTRUCTING FA FOR GIVEN RE

- Relationship between FA and RE.



Identities:

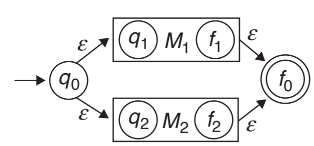
Basis:



Induction:

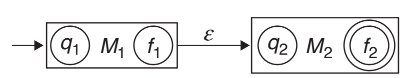
- **Union:** $L(r) = L\ (r_1) + L\ (r_2)$ i.e., $L\ (M) = L\ (M_1) \cup L\ (M_2)$

Let $M_1 = (Q_1, \Sigma_1, \delta_1, q_1, \{f_1\})$, $M_2 = (Q_2, \Sigma_2, \delta_2, q_2, \{f_2\})$ with $L\ (M_1) = L\ (r_1)$ and $L\ (M_2) = L\ (r_2)$, then $M = (Q_1 \cup Q_2 \cup \{q_0, f_0\}, \Sigma_1 \cup \Sigma_2, \delta, q_0, \{f_0\})$



- **Concatenation:**

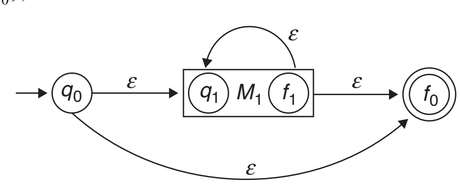
$L(r) = L\ (r_1) \cdot L\ (r_2)$ i.e., $L\ (M) = L\ (M_1) \cdot L\ (M_2)$



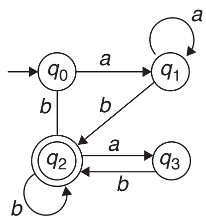
- **Closure:**

$L(r) = L(r)^*$ i.e., $L\ (M) = L\ (M_1)^*$

Let $M_1 = (Q_1, \Sigma_1, \delta_1, q_1, \{f_1\})$ then $L\ (M) = (Q_1 \cup \{q_0, f_0\}, \Sigma_1, \delta, q_0, \{f_0\})$



Example 17: The regular expression generated by the given FA.



(A) $(a + ba^*)\ b^*$ (B) $(aa^*b + bb^*)\ b^*$
(C) $(b + ab^*)\ a^*$ (D) $(ab + ba)^*$

Solution: (B)
q_2 is final state which is obtained with input symbol only 'b'. So, (C) or (D) is not true.
In (A) $\rightarrow$ ba^* is not defined in given *FA*. Instead bb^* is defined.

Pumping Lemma for Regular Sets

Theorem Let 'L' be an arbitrary regular language. Then there exists a positive integer, P with following property:

Given an arbitrary member, w of L having length at least P (i.e., $|w| \geq P$), w can be divided into 3-parts, $w = xyz$ $\exists$

- $|y| \geq 1$ (the middle part is non-empty)
- $|xy| \leq P$ (the first two parts have length atmost P)
- For each, $i \geq 0$, $xy^iz \in L$ (removing or repeating the middle part produces member of L)

Proof Let L be an arbitrary regular language. Then there is a *FA*, say M that decides L.
Let P be the number of states of M.
Let w be an arbitrary member of L, having length 'n' with $n \geq P$.
Let $q_0, q_1, \ldots q_n$ be states that M on input w. That is, for each i, after reading the first i symbols of w, M is at q_i.
q_0 is initial state of M. Also, since $w \in L$, q_n is a final state of M.
Let $x = w_1 \ldots w_c$, $y = w_{c+4} \ldots w_d$, $z = w_{d+1} \ldots w_n$. Then:

- $|y| \geq 1$
- $|xy| \leq P$
- M transitions from q_0 to q_c on x.
- M transitions from q_c to q_c on y.
- M transitions from q_c to q_n on z.

Thus, for every $i \geq 0$, M transitions from q_0 to q_n on xy^iz and so, xy^iz is a member of L.

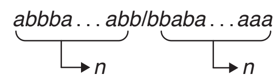
Note:

- Pumping lemma is used to verify that given language is not regular.
- Pumping lemma follows pigeon hole principle.

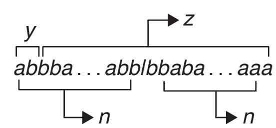
Example 18: The language, L is defined as:
$L = \{w_1w_2 : w_1, w_2 \in \{a, b\}^*, |w_1| = |w_2|\}$. Is the language regular?

(A) Regular
(B) Not regular
(C) Cannot be determined
(D) None of these

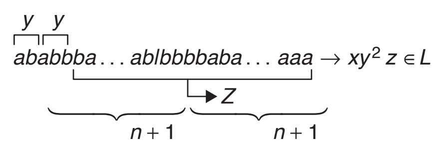
Solution: (A)
Fix pumping length, $K = 2$
For every proper strings in L, $(2n \geq 2)$



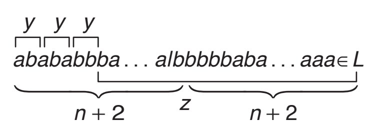
- Split in x, y, z with desired properties.



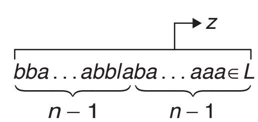
- Let $x = \varepsilon$, y = first two symbols, z = rest.



- xy^3z:



- $xy^oz \rightarrow$



$\therefore$ For every $i \geq 0$, $xy^iz \in L$. Hence given language is regular.

Closure Properties of Regular Sets

1. **Union:** If L and M are regular languages, LUM is regular language closed under union.
2. **Concatenation and Kleen closure:** If L and M are regular languages, L.M is regular language and L^* is also regular.
3. **Intersection:** $L \cap M$ is regular, if L and M are regular languages.
4. **Difference:** $L - M$ contains strings in 'L' but not M, where L and M are regular languages.
5. **Complementation:** The complement of language L is $\Sigma^*\!-\!L$.

Note: Since Σ^* is surely regular, the complement of a regular language is always regular. Where Σ^* is a universal language.

6. **Homomorphism:** If L is a regular language, h is homomorphism on its alphabet then $h\,(L) = \{h\,(w)\ |w$ is in $L\}$ is also a regular language.

Regular grammar

- **Grammar:** Generative description of a language.
- **Automaton:** Analytical description.
- A grammar is a 4-tuple, G = (V, Σ, R, S) where V: alphabet (variable) (non-terminals)

$\Sigma \subseteq V$ is set of terminal symbols.
$R \subseteq (V^+ \times V^*)$ is a finite set of production rules.
$S \in V - \Sigma$ is start symbol.

Notation

- Elements of $V - \Sigma$: $A, B, \ldots$
- Elements of Σ: $a, b \ldots$
- Rules $(\alpha, \beta) \in R$: $\alpha \to \beta$ or $\alpha \xrightarrow[G]{} \beta$
- Start symbol is written as S.
- Empty word: ε

Example 19: The regular expression that describe the language generated by grammar, $G = (\{S, A, B\}, \{a, b\}, S, \{S \to Aab, A \to Aab|B, B \to a\}$

(A) $(ab)^* a$
(B) $aab(ab)^*$
(C) $ab^* aa$
(D) $(a + ba)^*$

Solution: (B)
$S \to Aab \to Aab\ ab \to A\ ab\ abab \to Bababab$
$\to aababab \to aab(ab)^*$

Union of two Regular languages:
If L_1 and L_2 are two languages then
$L_1 \cup L_2 = \{w/w \in L_1 \text{ or } w \in L_2\}$
The union of two regular languages is also a regular language.
Let $M_1 = (Q_1, \Sigma, \delta_1, q_1, f_1)$
$M_2 = (Q_2, \Sigma, \delta_2, q_2, f_2)$
$M = M_1 U M_2$ can be given as
$M = (Q, \Sigma, \delta, q_0, f)$.
Where $Q = \{(r_1, r_2) \mid r_1 \in Q_1 \text{ and } r_2 \in Q_2\}$
i.e., Q is the Cartesian product of sets Q_1 and Q_2.
Σ is the alphabet, is the same in M_1 and M_2.
$\Sigma = \Sigma_1 \cup \Sigma_2$.
δ is the transition function given as:
$\delta(r_1, r_2), a = (\delta_1(r_1, a)\ \delta_2(r_2, a))$.
q_0 is the pair (q_1, q_2).
F is the set of pairs in which either member is an accept state of M_1 or M_2.
$F = \{(r_1, r_2) \mid r_1 \in F_1 \text{ or } r_2 \in F_2\}$

Types of Grammars

- Type 0: Unrestricted, recursively enumerable languages.
- Type 1: Context-sensitive grammar.
- Type 2: Context free grammar.
- Type 3: Regular grammar.

Type 0: Recursively enumerable grammar: (Turing Machine) (TM):

Every production rule is of form: $\alpha \to \beta$, where α and β are in $(V \cup T)^*$, i.e., there can be any strings of terminals and non-terminals (no-restriction).

Type 1: Context-sensitive Grammar: (Linear bounded automaton) (LBA):

Every production rule is of form, $\alpha \to \beta$ are in $(V \cup T)^*$ and $\alpha \neq \varepsilon$ and $|\beta| \geq |\alpha|$ i.e., any strings of terminals and non-terminals and length of string that can appear on RHS of production must be greater than or equal to length of string that can appear on LHS of production.

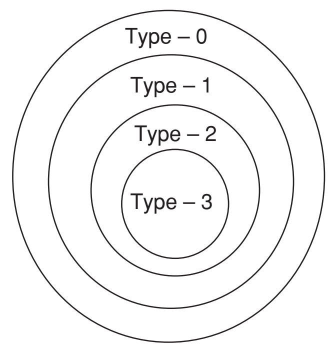
Type 2: Context-free grammar: (Push down automaton) (PDA):

Every production rule is of form, $A \to \alpha$ where α is in $(V \cup T)^*$ i.e., LHS of rule is single non-terminal and RHS can be any string of terminals and non-terminals.

Type 3: Regular grammar: (Finite automaton) (FA):

Every production is of form, $A \to aB$ or $A \to a$ where A and $B \in V$ and $a \in T$. That is, LHS of rule is non-terminal and RHS can be terminal (or) terminal followed by non-terminal.

Relationship between types of grammar:



- Regular sets are properly contained in CFL (Context Free Languages).
- The CFL's not containing empty string ε, are properly contained in CSL. (Context sensitive language).
- The CSL's are properly contained in Recursively enumerable languages.
- RG $\subset$ CFG $\subset$ CSL $\subset$ REG

Left-linear Grammar:
All productions have form: $A \to Bx$ or $A \to x$

Right-linear Grammar:
All productions have the form: $A \to xB$ or $A \to x$.

Note:

- The regular grammars characterize the regular sets i.e., a language is regular if and only if it has a left-linear grammar or if and only if it has a right-linear grammar.
- If L has a regular grammar, then L is a regular set.
- If L is a regular set, then L is generated by some left-linear grammar and by some right-linear grammar.

Arden's theorem: Let P and Q be two regular expressions over Σ. If P does not contain 'ε' then the following equation in R, namely $R = Q + RP$ has a unique solution given by $R = QP^*$.

Arden's Theorem to obtain regular expression from given transition diagram: The following steps are used to find the RE recognized by transition system.

The following assumptions are made regarding the transition system.

(i) The transition graph does not have ε-moves
(ii) It has only one initial state, q_o.
(iii) The states in the transition diagram are $q_o, q_1, q_2, \ldots q_n$.
(iv) Q_i, the regular expression represents the set of strings accepted by a system even though q_i is the final state.
(v) ${}^{a}ij$ denotes the regular expression representing the set of labels of edges from q_i to q_j. When there is no such edge ${}^{a}ij = \phi$.

We will get the following set of equations.

$$Q_1 = Q_1\alpha_{11} + Q_2\alpha_{12} + \ldots Q_n\alpha_{n1} + \varepsilon$$
$$Q_2 = Q_1\alpha_{12} + Q_2\alpha_{22} + \ldots Q_n\alpha_{n2}$$
$$\vdots$$
$$Q_n = Q_1\alpha 1n + Q_2\alpha_{2n} + \ldots Q_n\alpha_{nn}.$$

By Repeatedly applying substitutions and Arden's theorem, we can express Q_i in terms of α_{ij}'s.

For getting the set of strings recognized by the transition system, we have to take the union of all Q_i's corresponding to final states.

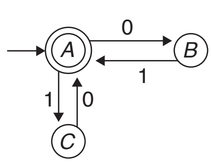
Construction of Regular Grammar from FA

Step I: Associate suitable variables like A, B, C … with states of automata.

Step II: Obtain the productions of the grammar as: If $\delta(A, a) = B$ then add production $A \to aB$ to list of productions of grammar, if B is a final state, then add either $A \to a$ or $B \to \varepsilon$, to list of productions of grammar.

Step III: The variable associated with initial state of automata is start symbol of grammar.

Example 20: Regular grammar generating language accepted by below automata is



(A) $A \to 0B|1C|\varepsilon$
$B \to 1A$
$C \to 0A$
(B) $A \to 1B|0C|\varepsilon$
$B \to 1A$
$C \to 0A$
(C) $A \to B|C|\varepsilon$
$B \to 1$
$C \to 0$
(D) $A \to 0A|1B|\varepsilon$
$B \to 1C$
$C \to 0A$

Solution: (A)
$A \to 0B$, $A \to 1C$, $B \to 1A$, $C \to 0A$
$\therefore$ A is final state, $A \to \varepsilon$

$\therefore A \to 0B\|1C\|\varepsilon$		$A \to 0B\|1C$
$B \to 1A$	(or)	$B \to 1A\|1$
$C \to 0A$		$C \to 0A\|0$

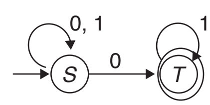
Construction of FA from given regular grammar

Given a regular grammar, G; a regular expression specifying $L(G)$ can be obtained directly as follows:

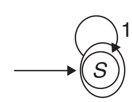
- Replace the '$\to$' symbol in productions of grammar by '=' symbol, to get set of equations.
- Solve the set of equations obtained above to get the value of variable, S, where S is start symbol of grammar, result is regular expression specifying $L(G)$.

Example 21: The Regular grammar and *FA* for given regular expression $\phi^* 1^* U\,(0\phi)^*$ is ____

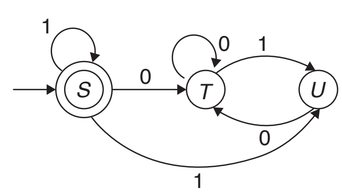
(A) $S \to 0S|1S|0$
$T \to 1T|\varepsilon$



(B) $S \to 1S|\varepsilon$

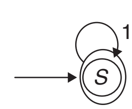


(C) $S \to 0T|1S|\varepsilon$
$T \to 0T|1U|\varepsilon$
$U \to 0T|1S$



(D) Cannot be determined

Solution: (B)
$\varnothing^*\,1^* \cup (0\varnothing)^* = \varnothing^* \cdot 1^* \cup \varnothing^* = \varepsilon \cdot 1^* \cup \varepsilon = 1^*.$



Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Find a regular expression for
   $L = \{uvu: u, v \in \{a, b\}^*, |u| = 2\}$
   (A) $(ab)^*a(ab)^*$
   (B) $(aa)^*ab(aa)^*$
   (C) $aa(a + b)^*bb + bb(a + b)^*aa$
   (D) $aa(a + b)^*aa + ab(a + b)^* ab + ba (a + b)^* ba + bb (a + b)^*bb$
2. Consider the regular expression, $R = 10 + (0 + 11)0^* 1$. The minimum number of states in any DFA accepting this regular expression is:
   (A) 5 (B) 4
   (C) 3 (D) 6
3. The following DFA accepts the set of all strings over $\{a, b\}$ that

   (A) Contains number of b's divisible by 3.
   (B) Contain number of a's and b's divisible by 3
   (C) Contain number of b's congruent to 3 modulo 4.
   (D) Contain any number of a's and b's
4. Consider the grammar, $S \rightarrow SS/a$. To get string of n terminals, the number of productions to be used is
   (A) n^2 (B) n
   (C) 2^{n+1} (D) $2n–1$
5. The language L is defined as, $L = \{a^i\, b^j\, c^{2j} |\ i \geq 0, j \geq 0\}$. Is this language L regular?
   (A) Yes (B) No
   (C) Cant be determined (D) None of these
6. The language, L is defined by set of strings over $\{a, b\}^*$ in which number of a's is a perfect cube. What is the nature of language, L?
   (A) Regular (B) Non-regular
   (C) Cant be determined (D) None of these
7. The language, L is defined over $\Sigma = \{0 – 7\}$. The string include 7, 16, 43, 61, 223, … The language generated is:
   (A) Alternate odd and even numbers
   (B) Octal representation of a number
   (C) Divisible by 7.
   (D) Octal representation of a number divisible by 7.
8. The language L, is defined as set of strings that start and end with equal number of a's and contain any number of b's. The grammar $L(G)$ for language L is defined with productions as:
   (A) $S \rightarrow aBa$
   $B \rightarrow \varepsilon|bB$
   (B) $S \rightarrow aB$
   $B \rightarrow a|bB$
   (C) $S \rightarrow aT|bS$
   $T \rightarrow aT|bT|a|b$
   (D) $S \rightarrow B|aSa$
   $B \rightarrow \varepsilon|bB$
9. If the regular set A is represented by $A = ((01)^*1^*)^*$. And the regular set B is represented by $B = (01 + 1)^*$, which of the following is true?
   (A) $A \subset B$
   (B) $B \subset A$
   (C) $A = B$
   (D) A and B are incomparable
10. The language, L that is generated over $\Sigma = \{0, 1\}$ for regular expression $L(r) = (0 + 10)^*\, 1\, (1 + 10)^*$
   (A) Any string whose number of 1's length is greater than or equal to 3.
   (B) Any string that has no substring 110.
   (C) Any string that has no substring 00 after first 11.
   (D) Any string that has only one occurrence of substring 010.
11. The R.E $L(r) = (a^+b^*)\ U\ \varepsilon$. Is the grammar with productions generated over non-terminals $\{S, A\}$ ambiguous?
   (A) Yes (B) No
   (C) Can't be determined (D) None
12. The number of states in the obtained Moore machine while converting the given mealy to Moore are:

   (A) 5 (B) 6
   (C) 4 (D) 7
13. The language L is defined as $L = \{0^i 1^j / i \neq j\}$ over $\{0, 1, 2\}$, $A = \{0^i\ 1^j / i \geq 0, j \geq 0\}$ and $B = \{0^i\ 1^j / i = j\}$. For language, L to be non-regular. What should be relation between A, B, L?
   (A) $B = (A \cup L)^c$ (B) $B = A \cup L$
   (C) $B = A \cap \overline{L}$ (D) $B = A^c$
14. Which of following grammars are unambiguous?
   (A) $S \rightarrow (S)\ S|[S]\ S|\varepsilon$ (B) $S \rightarrow S(S)S|\varepsilon$
   (C) $S \rightarrow aS|Sa|a$ (D) $S \rightarrow a|Sa|bSS|Ssb|SbS$

15. What will be number of final states obtained in DFA for language $L = \{w/w$ contains at least two 0's and atmost one 1$\}$ over $\Sigma = \{0, 1\}$.

(A) 2 (B) 1
(C) 3 (D) 4

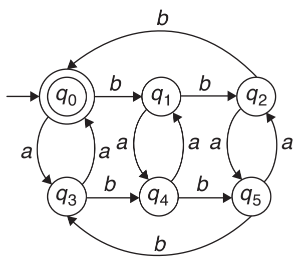
Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Which of the following Regular expression is equal to given regular expression: $(b + aa^* b) + (b + aa^*b)(a + ba^* b)^* (a + ba^* b)$

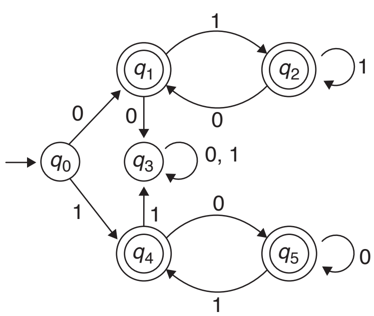
(A) $Ab (b + baa^*)$ (B) $a^*b (a + ba^* b)$
(C) $a^* b (a + ba^* b)^*$ (D) $ab (b + aa^*b)^*$

2. The following DFA accepts set of all strings over $\{a, b\}$ that contain



(A) Number of a's even and number of b's odd.
(B) Consecutive a's and b's
(C) Contain bbb as substring
(D) Number of a's even and number of b's divisible by three.

3. The regular language $L(r)$ for the given FSM is:

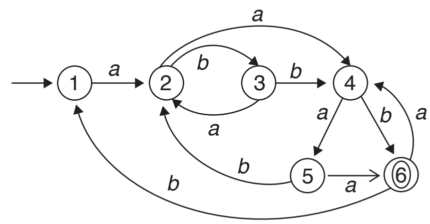


(A) It can start with zero followed by any number of 1's but no two consecutive 0's.
(B) It can start with 1, followed by any number of 0's but no two consecutive 1's.
(C) It is a combination of 0's and 1's but no two consecutive 0's or 1's.
(D) Both (A) and (B).

4. The language, L is defined as a set of non-palindromes over $\{a, b\}$. Is L regular?

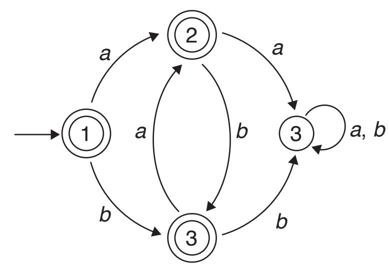
(A) Yes (B) No
(C) Cannot be determined (D) None of above

5. The DFA, for language, L over $\Sigma = \{a, b\}$ is given below. What will be number of states in minimized DFA.



(A) 4 (B) 6
(C) 2 (D) 3

6. The minimal DFA given below is defined for language, $L = \{w \in \{a, b\}^*\}$ over $\Sigma = \{a, b\}$. The 'L' is:



(A) Strings that contain equal number of a's and b's that have adjacent characters same.
(B) Contains adjacent characters same
(C) No two adjacent characters are same
(D) Starts and ends with same character that have adjacent character same.

7. The regular grammar $L(G)$ contains productions, P for language, $L = \{w \in \{a, b\}^* /$ there is at least one a$\}$ are:

(A) $S \to aS|bS|a|aT$
$T \to aT|bT|a|b$
(B) $S \to aS|bS|\varepsilon$
(C) $S \to aBb|bB$
$B \to a|b$
(D) $S \to bB$
$B \to b|\varepsilon$

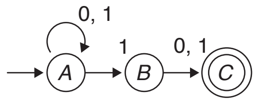
8. The regular expression for a language is defined as $((a^* b)^* (bc^*)^*)$. The total number of final states obtained in both NFA and DFA are respectively:

(A) 4, 2 (B) 1, 3
(C) 1, 5 (D) 2,3

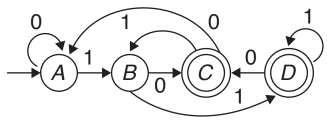
9. The language, L is defined as $\{w/w$ has n occurrences of 0's where n mod 5 is 3$\}$ over $\Sigma = \{0, 1\}$. The number of final states obtained in the DFA for L is:

(A) 4 (B) 5
(C) 1 (D) 2

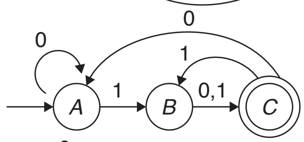
10. Which of the following is an equivalent DFA for the following NFA?



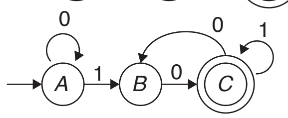
(A)



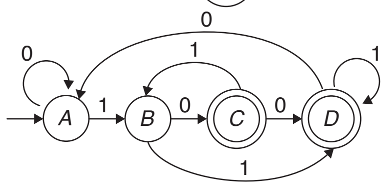
(B)



(C)



(D)



11. A regular grammar over alphabet $\Sigma = \{a, b, c, d\}$ whose language, is set of strings that contain exactly two b's is:

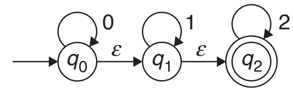
(A) $S \to aS|bS|cS|dA$
$A \to aA|bA|cA|dA|\varepsilon$

(B) $S \to aS|cS|dS|bB$
$B \to aB|cB|dB|bC,$
$C \to aC|cC|dC|\varepsilon$

(C) $S \to aS|bS|cS|dA$
$A \to aA|bB|cC$
$B \to b$
$C \to c$

(D) None of above

12. The following NFA contains ε-moves with 5, transitions. If this NFA with ε-moves is converted to NFA without ε-moves, what will be total number of transitions in obtained NFA?



(A) 5 (B) 4
(C) 6 (D) 3

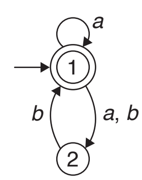
13. The regular expression, $r = (a + b)^*$. One more regular expression which represents same regular expression 'r' is:

(A) $a^* + b^*$ (B) $a^* \cdot b^*$
(C) $a^*(ba^*)^*$ (D) $(a + b)^* (a + b)$

14. The Regular grammar, $L(G)$ is defined for L with productions as $S \to Aab$, $A \to Aab|aB$, $B \to a$. What is Language generated by $L(G)$?

(A) Containing alternative a's and b's
(B) Containing alternative a's and b's, begins with an 'a' and ends with a 'b'.
(C) 'aa' followed by at least one set of alternating ab's.
(D) Consecutive aa's followed by 'b'.

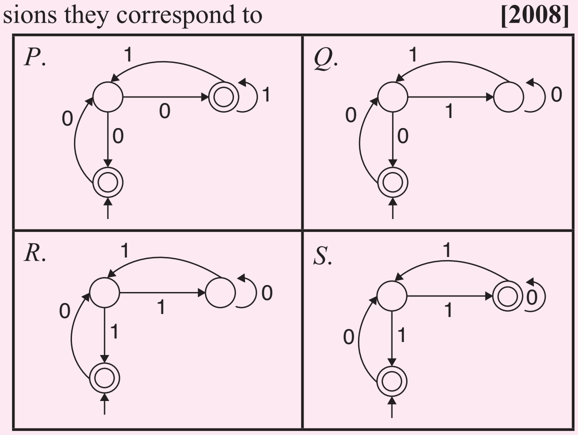
15. The number of final states in DFA after converting the NFA given below is:



(A) 4 (B) 2
(C) 3 (D) 1

Previous Years' Questions

1. Match the following NFAs with the regular expressions they correspond to **[2008]**



1. $\in + 0(01^*1 + 00)^*01^*$
2. $\in + 0(10^*1 + 00)^*0$
3. $\in + 0(10^*1 + 10)^*1$
4. $\in + 0(10^*1 + 10)^*10^*$

(A) P–2, Q–1, R–3, S–4
(B) P–1, Q–3, R–2, S–4
(C) P–1, Q–2, R–3, S–4
(D) P–3, Q–2, R–1, S–4

2. Which of the following are regular sets?

I. $\{a^n b^{2m} \mid n \geq 0, m \geq 0\}$
II. $\{a^n b^m \mid n = 2m\}$
III. $\{a^n b^m \mid n \neq m\}$
IV. $\{xcy \mid x, y \in \{a, b\}^*\}$ **[2008]**

(A) I and IV only (B) I and III only
(C) I only (D) IV only

3. Which one of the following languages over the alphabet $\{0, 1\}$ is described by the regular expression: $(0 + 1)^*0(0 + 1)^*0(0 + 1)^*$? **[2009]**

(A) The set of all strings containing the substring 00.
(B) The set of all strings containing atmost two 0's.
(C) The set of all strings containing at least two 0's.

(D) The set of all strings that begin and end with either 0 or 1.

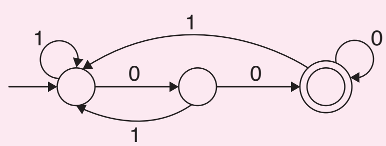
4. Which one of the following is FALSE? **[2009]**
(A) There is a unique minimal DFA for every regular language.
(B) Every NFA can be converted to an equivalent PDA.
(C) Complement of every context-free language is recursive.
(D) Every non-deterministic PDA can be converted to an equivalent deterministic PDA.

5. Match all items in Group 1 with correct options from those given in Group 2. **[2009]**

Group 1		Group 2	
P.	Regular expression	1.	Syntax analysis
Q.	Pushdown automata	2.	Code generation
R.	Dataflow analysis	3.	Lexical analysis
S.	Register allocation	4.	Code optimization

(A) P–4, Q–1, R–2, S–3
(B) P–3, Q–1, R–4, S–2
(C) P–3, Q–4, R–1, S–2
(D) P–2, Q–1, R–4, S–3

6.



The above DFA accepts the set of all strings over {0, 1} that **[2009]**
(A) Begin either with 0 or 1
(B) End with 0
(C) End with 00
(D) Contain the substring 00.

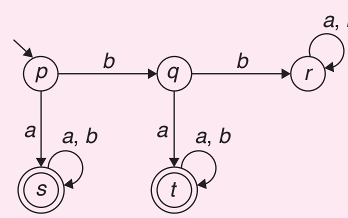
7. Let $L = \{w \in (0 + 1)^* \mid w$ has even number of 1's$\}$, i.e., L is the set of all bit strings with even number of 1's. Which one of the regular expressions below represents L? **[2010]**
(A) $(0^*10^*1)^*$
(B) $0^*(10^*10^*)^*$
(C) $0^*(10^*1^*)^*0^*$
(D) $0^*1(10^*1)^*10^*$

8. Consider the languages $L_1 = \{0^i1^j \mid i \neq j\}$. $L_2 = \{0^i1^j \mid i = j\}$, $L_3 = \{0^i1^j \mid i = 2j + 1\}$. $L_4 = \{0^i1^j \mid i \neq 2j\}$. Which one of the following statements is true? **[2010]**
(A) Only L_2 is context free
(B) Only L_2 and L_3 are context free
(C) Only L_1 and L_2 are context free
(D) All are context free

9. Let w be any string of length n in $\{0, 1\}^*$. Let L be the set of all substrings of w. What is the minimum number of states in a non-deterministic finite automaton that accepts L? **[2010]**
(A) n-1
(B) n
(C) n+1
(D) 2^{n-1}

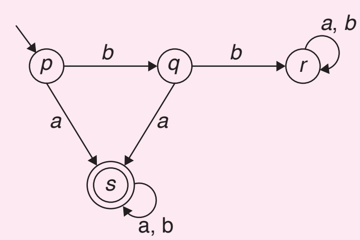
10. Let P be a regular language and Q be a context-free language such that $Q \subseteq P$ (For example let P be the language represented by the regular expression p^*q^* and Q be $\{p^nq^n\}$ $n \in N\}$, Then which of the following is ALWAYS regular? **[2011]**
(A) $P \cap Q$
(B) $P - Q$
(C) $\Sigma^* - P$
(D) $\Sigma^* - Q$

11. A deterministic finite automaton (DFA) D with alphabet $\Sigma = \{a, b\}$ is given below.

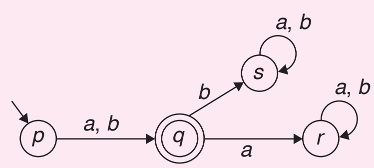


Which of the following finite state machines is a valid minimal DFA which accepts the same language as D? **[2011]**

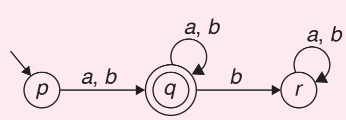
(A)



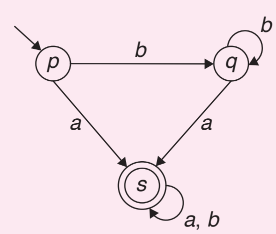
(B)



(C)

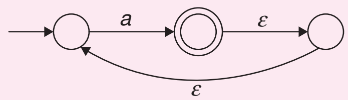


(D)



12. Given the language $L = \{ab, aa, baa\}$, which of the following strings are in L^*? **[2012]**
(1) *abaabaaabaa*
(2) *aaaabaaaa*
(3) *baaaaabaaaab*
(4) *baaaabaa*
(A) 1, 2 and 3
(B) 2, 3 and 4
(C) 1, 2 and 4
(D) 1, 3 and 4

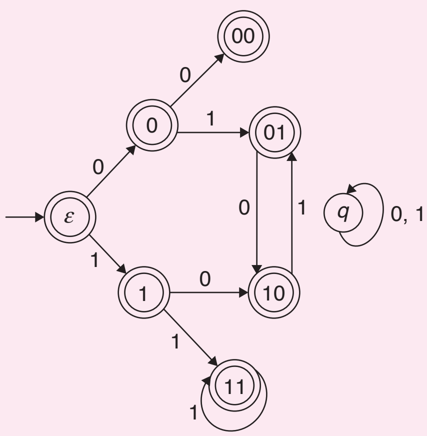
13. What is the complement of the language accepted by the NFA shown below?



Assume $\Sigma = \{a\}$ and ε is the empty string. **[2012]**

(A) $\varnothing$ (B) $\{\varepsilon\}$
(C) a^* (D) $\{a, \varepsilon\}$

14. Consider the set of strings on {0, 1} in which, every substring of 3 symbols has atmost two zeros. For example, 001110 and 011001 are in the language, but 100010 are not. All strings of length less than 3 are also in the language. A partially completed DFA that accepts this language is shown below.



The missing arcs in the DFA are **[2012]**

(A)

	00	01	10	11	q
00	1	0			
01				1	
10	0				
11			0		

(B)

	00	01	10	11	q
00		0			1
01		1			
10				0	
11		0			

(C)

	00	01	10	11	q
00		1			0
01		1			
10			0		
11		0			

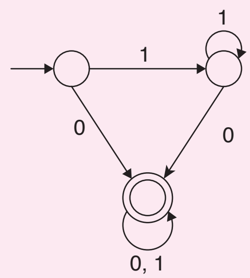
(D)

	00	01	10	11	q
00		1			0
01				1	
10	0				
11			0		

15. Consider the languages $L_1 = \Phi$ and $L_2 = \{a\}$. Which one of the following represents $L_1 L_2^* U L_1^*$? **[2013]**

(A) $\{\in\}$ (B) Φ
(C) a^* (D) $\{\in, a\}$

16. Consider the DFA A given below

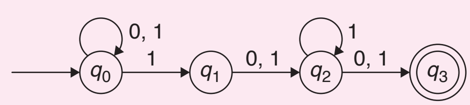


Which of the following are FALSE?

1. Complement of $L(A)$ is context-free.
2. $L(A) = L((11^*0 + 0)(0 + 1)^*0^*1^*)$
3. For the language accepted by A, A is the minimal DFA.
4. A accepts all strings over {0, 1} of length at least 2. **[2013]**

(A) 1 and 3 only (B) 2 and 4 only
(C) 2 and 3 only (D) 3 and 4 only

17. Consider the finite automaton in the following figure. **[2014]**



What is the set of reachable states for the input string 0011?

(A) $\{q_0, q_1, q_2\}$ (B) $\{q_0, q_1\}$
(C) $\{q_0, q_1, q_2, q_3\}$ (D) $\{q_3\}$

18. If $L_1 = \{a^n | n \geq 0\}$ and $L_2 = \{b^n | n \geq 0\}$, consider the statements **[2014]**

(I) $L_1 \cdot L_2$ is a regular language
(II) $L_1 \cdot L_2 = \{a^n b^n | n \geq 0\}$

Which one of the following is CORRECT?

(A) Only (I) (B) Only (II)
(C) Both (I) and (II) (D) Neither (I) nor (II)

19. Let $L_1 = \{w \in \{0, 1\}^* | w$ has at least as many occurrences of (110)'s as (011)'s}. Let $L_2 = \{w \in \{0, 1\}^* | w$ has at least

as many occurrences of (000)'s as (111)'s}. Which one of the following is TRUE? **[2014]**

(A) L_1 is regular but not L_2
(B) L_2 is regular but not L_1
(C) Both L_1 and L_2 are regular
(D) Neither L_1 nor L_2 are regular

20. The length of the shortest string NOT in the language (over $\Sigma = \{a, b\}$) of the following regular expression is ______. **[2014]**

$a^*b^*(ba)^*a^*$

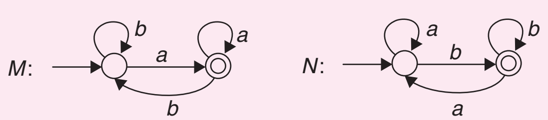
21. Let Σ be finite non-empty alphabet and let 2^{Σ^*} be the power set of Σ^*. Which one of the following is TRUE? **[2014]**

(A) Both 2^{Σ^*} and Σ^* are countable
(B) 2^{Σ^*} is countable and Σ^* is uncountable
(C) 2^{Σ^*} is uncountable and Σ^* is countable
(D) Both 2^{Σ^*} and Σ^* are uncountable

1. $\varepsilon + 0\,(01^*\,1 + 00)^*\,01^*$
2. $\varepsilon + 0\,(10^*\,1 + 00)^*\,0$
3. $\varepsilon + 0\,(10^*\,1 + 10)^*\,1$
4. $\varepsilon + 0\,(10^*\,1 + 10)^*\,10^*$

(A) $P-2, Q-1, R-3, S-4$
(B) $P-1, Q-3, R-2, S-4$
(C) $P-1, Q-2, R-3, S-4$
(D) $P-3, Q-2, R-1, S-4$

22. Consider the DFAs M and N given above. The number of states in a minimal DFA that accepts the language $L(M) \cap L(N)$ is _______ **[2015]**



23. The number of states in the minimal deterministic finite automaton corresponding to the regular expression $(0 + 1)^*(10)$ is ______ **[2015]**

24. Which of the following languages is/are regular? **[2015]**

L_1: $\{wxw^R | w, x \in \{a, b\}^*$ and $|w|, |x| > 0\}$, w^R is the reverse of string w

L_2: $\{a^nb^m | m \neq n$ and $m, n \geq 0\}$

L_3: $\{a^pb^qc^r | p, q, r \geq 0\}$

(A) L_1 and L_3 only
(B) L_2 only
(C) L_2 and L_3 only
(D) L_3 only

25. Consider the alphabet $\Sigma = \{0, 1\}$, the null/empty string λ and the sets of strings X_0, X_1 and X_2 generated by the corresponding non-terminals of a regular grammar. X_0, X_1 and X_2 are related as follows

$X_0 = 1X_1$
$X_1 = 0X_1 + 1X_2$
$X_2 = 0X_1 + \{\lambda\}$

Which one of the following choices precisely represents the strings in X_0? **[2015]**

(A) $10(0^* + (10)^*)1$
(B) $10(0^* + (10)^*)^*1$
(C) $1(0 + 10)^*1$
(D) $10(0 + 10)^*1 + 110(0 + 10)^*1$

26. Let L be the language represented by the regular expression $\Sigma^*\ 0011\ \Sigma^*$ where $\Sigma = \{0, 1\}$. What is the minimum number of states in a DFA that recognizes $\overline{L}$ (complement of L)? **[2015]**

(A) 4
(B) 5
(C) 6
(D) 8

27. Which of the following languages is generated by the given grammar? **[2016]**

$S \rightarrow aS \mid bS \mid \varepsilon]$

(A) $\{a^n\,b^m \mid n, m \geq 0\}$
(B) $\{w \in \{a, b\}^* \mid$ w has equal number of a's and b's$\}$
(C) $\{a^n \mid n \geq 0\}\ U\ \{b^n \mid n \geq 0\}\ U\ \{a^nb^n \mid n \geq 0\}$
(D) $\{a, b\}^*$

28. Which of the following decision problems are undecidable? **[2016]**

I. Given NFAs N_1 and N_2, is $L(N_1) \cap L(N_2) = \Phi$?
II. Given a CFG $G = (N, \Sigma, P, S)$ and a string $x \in \Sigma^*$, does $x \in L(G)$?
III. Given CFGs G_1 and G_2, is $L(G_1) = L(G_2)$?
IV Given a TM M, is $L(M) = \Phi$?

(A) I and IV only
(B) II and III only
(C) III and IV only
(D) II and IV only

29. Which one of the following regular expressions represents the language: *the set of all binary strings having two consecutive 0's and two consecutive 1s?* **[2016]**

(A) (0+1)* 0011 (0+1)* + (0+1)* 1100 (0+1)*
(B) (0+1)* (00(0+1)*11 + 11 (0+1)*00) (0+1)*
(C) (0+1)* 00 (0+1)* + (0+1)* 11 (0+1)*
(D) 00 (0+1)* 11 + 11 (0+1)* 00

30. The number of states in the minimum sized **DFA** that accepts the language defined by the regular expression (0+1)* (0+1) (0+1)* is ______ . **[2016]**

31. Language L_1 is defined by the grammar: $S_1 \rightarrow aS_1b \mid \in$
Language L_2 is defined by the grammar: $S_2 \rightarrow abS_2 \mid \in$

Consider the following statements:
P:L_1 is regular
Q:L_2 is regular
Which one of the following is TRUE? **[2016]**
(A) Both P and Q are true
(B) P is true and Q is false
(C) P is false and Q is true
(D) Both P and Q are false

32. Consider the following two statements:

I. If all states of an NFA are accepting states then the language accepted by the NFA is Σ^*.

II. There exists a regular language A such that for all languages B, A $\cap$ B is regular.

Which one of the following is **CORRECT**? **[2016]**
(A) Only **I** is true
(B) Only **II** is true
(C) Both **I** and **II** are true
(D) Both **I** and **II** are false

33. Consider the language L given by the regular expression $(a + b)^*b\ (a + b)$ over the alphabet $\{a, b\}$. The smallest number of states needed in a deterministic finite-state automaton (DFA) accepting L is ________. **[2017]**

34. The minimum possible number of states of a deterministic finite automaton that accepts the regular language $L = \{w_1aw_2 | w_1, w_2 \in \{a, b\}^*, |w_1| = 2, |w_2| \geq 3\}$ is ___________. **[2017]**

35. Let δ denote the transition function and $\hat{\delta}$ denote the extended transition function of the $\in$-NFA whose transition table is given below:

δ	$\in$	a	b
$\rightarrow q_0$	$\{q_2\}$	$(q_1\}$	$\{q_0\}$
q_1	$\{q_2\}$	$\{q_2\}$	$\{q_3\}$
q_2	$\{q_0\}$	$\varnothing$	$\varnothing$
q_3	$\varnothing$	$\varnothing$	$(q_2\}$

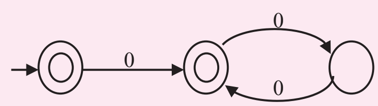
Then $\hat{\delta}\ (q_2, aba)$ is **[2017]**
(A) $\varnothing$ (B) $\{q_0, q_1, q_3\}$
(C) $\{q_0, q_1, q_2\}$ (D) $\{q_0, q_2, q_3\}$

36. Let N be an NFA with n states. Let k be the number of states of a minimal DFA which is equivalent to N. Which one of the following is necessarily true? **[2018]**
(A) $k \geq 2^n$ (B) $k \geq n$
(C) $k \leq n^2$ (D) $k \leq 2^n$

37. Given a language L, define L^i as follows:

$$L^0 = \{\varepsilon\}$$
$$L^i = L^{i-1}.\ L \text{ for all } i > 0$$

The order of a language L is defined as the smallest k such that $L^k = L^{k+1}$. Consider the language L_1 (over alphabet 0) accepted by the following automaton.



The order of L_1 is ______. **[2018]**

Chapter 2

Context Free Languages and Push Down Automata

LEARNING OBJECTIVES

- *Context free grammar*
- *Context free language*
- *Ambiguity in context free grammars*
- *Removing ε-productions*
- *Removing unit productions*
- *Normal forms*
- *Chomsky's normal form*
- *Greiback normal form*
- *Closure properties of CFL's*
- *Push down automata*
- *PDAs accepting by final state and empty stack are equivalent*
- *Converting CFG to PDA*
- *Deterministic PDA*

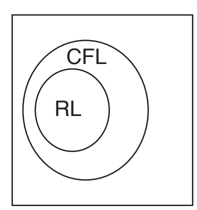
Context Free Grammar

- A context free grammar (CFG) is a finite set of variables (non-terminals) each of which represents a language. The language represented by variables is described recursively in terms of each other. The primitive symbols are called terminals.
- The rules relating variables are called productions. A typical production states that the language associated with a given variable contains strings that are formed by concatenating strings from languages of certain other variables.
- CFG is a collection of three things;
  An alphabet Z of letters called terminals.
  A set of symbols called non-terminals, one of which is a start symbol, S.
  A finite set of productions of the form:
  One terminal $\to$ finite set of terminals and/or non-terminals.
- A CFG is defined as: $G = (V, T, P, S)$
  Where
  $V \to$ Finite set of variables (non-terminals)
  $T \to$ Finite set of terminals (symbols)
  $P \to$ Finite set of productions, each, production is of the form,
  $A \to \alpha, A \in V, \alpha \in (V \cup T)^*$
  $S \to$ Start symbol

Context Free Language (CFL)

The language generated by CFG is a set of all strings of terminals that can be produced from start symbols, using the productions as substitutions. A language generated by a CFG is called context free language (CFL).

Note: Every regular grammar is context free, so a regular language (RL) is also context free.
Family of RL's is proper subset of CFL's.
i.e., RL $\subset$ CFL

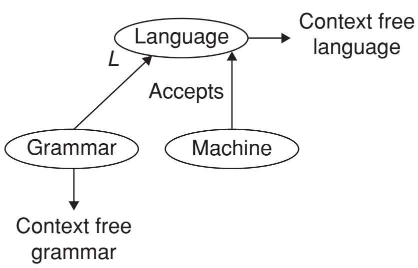


Solved Examples

Example 1: What is the language that is generated by CFG, $G = S \to AB|A \to +/–|B \to CB/C|C \to 0/1/2/ \dots 9$.
(A) Set of all rational numbers
(B) Set of all integers
(C) Set of all natural numbers
(D) Set of all complex numbers

Solution: (B)
$S \to AB|A \to +/–|B \to CB/C|C \to 0/1/2/ \dots 9$
Consider-18 (integer)

$S \rightarrow AB$
$\rightarrow -B$
$\rightarrow -CB$
$\rightarrow -1B$
$\rightarrow -18$



Ambiguity in Context Free Grammars

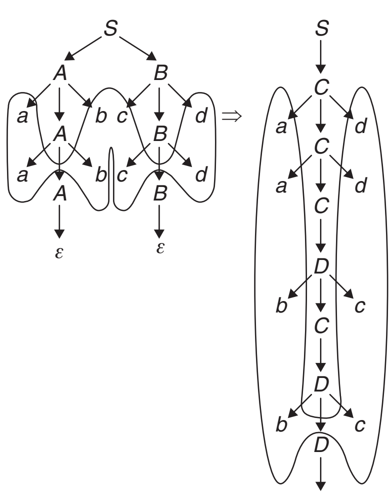
A CFG, G is called ambiguous if there is $w \in L(G)$ such that w has (at least) two different parse trees with respect to G.

Example 2: The language, $L = \{a^n\ b^n\ c^m\ d^m / n \geq 0,\ m \geq 0\} \cup \{a^n b^m c^m d^n / n \geq 0,\ m \geq 0\}$ is designed in CFG, G. The Grammar is
(A) Ambiguous
(B) Unambiguous
(C) Cannot be determined
(D) None of above

Solution: (A)
CFG G for given language L is:

$S \rightarrow AB|C$
$A \rightarrow aAb|\varepsilon$
$B \rightarrow cBd|\varepsilon$
$C \rightarrow aCd|$D
$D \rightarrow bDc|\varepsilon$

It's an inherently ambiguous grammar.
Consider string, aabbccdd



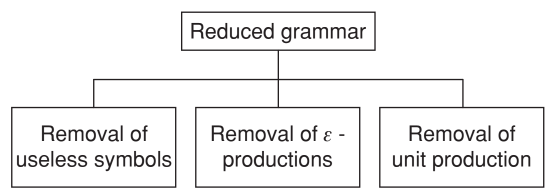
Note:
- A context free language with property that all grammars that generate it are ambiguous is inherently ambiguous.
- Inherently ambiguous grammars cannot convert to unambiguous grammars.

Minimization of Context Free Grammar

- Grammar may consist of some extra symbols (non-terminals). Having extra symbols unnecessarily increases the length of grammar.
- Simplification of grammar means reduction of grammar.

The properties of reduced grammar are:

1. Each variable (non-terminal) and each terminal of G appears in the derivation of some word in L.
2. There should not be any production as $X \rightarrow Y$ where X and Y are non-terminals.
3. If ε is not in language L, then there need not be production $X \rightarrow \varepsilon$.



Removal of Useless Symbols

- Any symbol is useful when it appears on right hand side, in the production rule and generates some terminal string. If no such derivation exists, then it is supposed to be a useless symbol.
- A symbol P is useful, if there exists some derivation

$$S^* \Rightarrow \alpha PB \text{ and } \alpha PB \overset{*}{\Rightarrow} W$$

Then P is said to be useful symbol.

Example 3: A grammar G', is generated by removing useless symbols from G defined below. The obtained G' contains productions:

$S \rightarrow aA|bB$
$A \rightarrow aA|a$
$B \rightarrow bB$
$D \rightarrow ab|Ea$
$E \rightarrow aC|d$

(A) $S \rightarrow aA$
$A \rightarrow aA|a$
(B) $S \rightarrow aS|bA|C$
$A \rightarrow a$
$C \rightarrow aCd$
(C) $S \rightarrow aA|bB$
$A \rightarrow aA|a$
$B \rightarrow bB$
(D) Cannot remove useless symbols

Solution:

$S \rightarrow aA \rightarrow aaA \rightarrow aaaA \rightarrow aaaa$ ✓

$B \rightarrow bB \rightarrow bbB \rightarrow bbbB \rightarrow bbbbB$ ..... (string cannot be generated)

$\therefore$ B is useless

D and E cannot be generated from 'S'. So, eliminate. Hence G' contains

$\therefore$ $S \rightarrow aA$

$A \rightarrow aA|a$

Removing ε-Productions

A production of the form $A \rightarrow \varepsilon$ is called an ε-production. If A is a non-terminal and $A \rightarrow (^*)\ \varepsilon$, then A is called a 'nullable non-terminal'. So eliminate such productions without changing meaning of grammar.

Example 4: The grammar, G is given below. The CFG generated after eliminating ε-production is:

$S \rightarrow ABC$
$A \rightarrow BC|a$
$B \rightarrow bAC|\in$
$C \rightarrow cAB|\in$

(A) $S \rightarrow ABC|AB|BC|CA$
$A \rightarrow BC|B|C$
$B \rightarrow bAC|bA|bC$
$C \rightarrow cAB|cA|cB$

(B) $S \rightarrow ABc$
$A \rightarrow BC$
$B \rightarrow bAC$
$C \rightarrow cAB$

(C) $S \rightarrow ABC|BC|AC|AB|A|B|C$
$A \rightarrow BC|B|C|a$
$B \rightarrow bAC|bA|bC|b$
$C \rightarrow cAB|cA|cB|c$

(D) None of these

Solution (C)

$B \rightarrow \in, C \rightarrow \in$

$\Rightarrow$ $A \rightarrow \in$

$\therefore$ Remove ε-productions and obtained CFG is Choice (C).

Removing Unit Productions

- A production of form $A \rightarrow B$, where A and B are both non-terminals, is called a 'unit production'.
- Presence of unit production in a grammar increases the cost of derivation.

Example 5: The total number of productions obtained by removing unit production from the Grammar,

$A \rightarrow PQ$
$P \rightarrow 0$
$Q \rightarrow R|1$
$R \rightarrow S$
$S \rightarrow W|1R$
$W \rightarrow 2|P1$

(A) 9 (B) 2
(C) 3 (D) 5

Solution: (A)

$A \rightarrow PQ$

$Q \rightarrow R \rightarrow S \rightarrow W \rightarrow 2$

$\Rightarrow$ $Q, R, S \rightarrow$ Unit production

$A \rightarrow PQ$

$P \rightarrow 0$

$Q \rightarrow R|1$
$\quad\downarrow$

$\Rightarrow$ $Q \rightarrow 2|P1|1R|1$ (substitute the production of R, S, W)

$\therefore$ $A \rightarrow PQ$

$P \rightarrow 0$

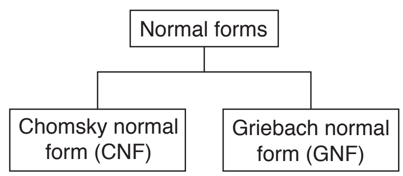
$Q \rightarrow 2|\ P1|\ 1R|\ 1$

$R \rightarrow 2|\ P1|\ 1R$

$\therefore$ 9 – Productions

Normal Forms

- It is necessary to have a grammar in some specific form so, grammar normalization is needed.



That is, There should be fixed number of terminals and non-terminals, in CFG.

Chomsky's Normal Form (CNF)

- A context free grammar (CFG), $G = (V, \Sigma, R, S)$ is said to be in CNF, if and only if every rule in R is of one of the following forms
  1. $A \rightarrow a$, for some $A \in V$ and some $a \in \Sigma$
  2. $A \rightarrow BC$, for some $A \in V$ and $B, C \in V \cup \{S\}$
  3. $S \rightarrow \varepsilon$
- Every rule either replaces a variable by a single character or by a pair of variables except the start symbol and the only rule that can have the empty word as it's right hand side must have start symbol as it's left hand side.

Note: Every parse tree for a grammar in CNF must be a binary tree and the parse tree for any non-empty word cannot have any leaves labeled with ε in it.

Transforming of a grammar to CNF

- In order to construct the grammar G in CNF that is equivalent to a given grammar G, first identify how exactly G can violate the rules for a CNF. Since CNF only restricts the rules in G, see only at R. The 'bad' cases of rules are:
- $A \rightarrow uSv$ where $A \in V$ and $u, v \in (V \cup \Sigma)^*$. The start symbol must not appear on the right-hand side of any rule. This is called 'start symbol rule'.

- **To remove 'start symbol rule',** add a new symbol, so make it the start symbol in new grammar G_1, and add the single rule $S_0 \to S$ to R to get the rules for G_1. Since S_0 does not appear in any rules, the new grammar has no start symbol rules.
  - $A \to \varepsilon$ where $A \in V \cup \{S\}|$. The only symbol that can be replaced by the word is start symbol. This is called 'ε-rules'.
- **To remove 'ε-rules',** identify all variables that can yield the empty string, either directly or indirectly.

  These variables are 'nullable'. Remove all direct rules $A \to \varepsilon$ from the grammar and fix up the grammar by removing all occurrences of nullable variables from the right hand sides of all rules.

  $A \to B$ where $A, B \in V$. The only rules involving variables on the right-hand side must have exactly two of them. This is called 'unit rules'.
- **To remove 'Unit rules',** identify a set of unit pairs. These are pairs of symbols (A, B), where $A \overset{*}{\Rightarrow} B$. Then remove all unit rules by copying right-hand sides. If there is a rule $A \to B$, (A, B) is a unit pair. Then, if there is a rule $B \to W$, derive W from A by $A \to B$, $B \to W$. To remove the unit rule and still generate an equivalent grammar, add the right-hand side W to the rules for A directly, $A \to W$.

  $A \to W$ where $A \in V$, $W \in (V \cup \Sigma)^*$ and W contains at least one character and at least one variable. The only rules where character appear on right-hand side must have exactly one character as right-hand side. This is called 'mixed rules'.
- **To remove 'mixed rules',** Let $A \to W \in R_3$ is a mixed rules. Then write W as $W = V_0\, C_1 V_1 \ldots V_{n-1} C_n V_n$, where $C_i \in \Sigma$ are occurrences of characters, and the $V_i \in V^*$ are strings of only variables. Then add a new symbol, C_i to V_4 for every character C_i and add the rules $C_i \to c_i$ to R_4. Finally define $W^1 := V_0\, C_1\, V_1 \ldots V_{n-1}\, C_n\, V_n \in V^*$ and add rules $A \to W'$ to R_4. If the rule $A \to W$ is part of the derivation for some word, replace that single rule by applying rule $A \to W'$ first and then replacing all C_i by c_i using their respective rules.

  $\boxed{A \to w}$ Where $A \in V$ and $W \in (V \cup \Sigma)^*$ with $|w| > 2$. Rules must have one symbol (character) or two variables (two variables as right hand side). These are called long rules.
- **To remove 'long rules',** Let $A \to B_1 \ldots B_n$ be a long rule, i.e., $n > 2$. B_i is all variables. Break up every single long rule, into several 'short' rules, by introducing new 'helper variables' and splitting right hand side from left to right: add new symbols $A_1, \ldots A_{n-2}$ to set of variables and add following rules to R_5: $A \to B_1 A_1, A_1 \to B_2 A_2, \ldots A_{n-2} \to B_{n-1} B_n$.

Example 6: Consider grammar, $G = S \to ASB$, $A \to aAS|a|\varepsilon$, $B \to SbS|A|bb$. The CNF generated contains ____ non-terminals.

(A) 5 (B) 6
(C) 9 (D) 11

Solution: (C)

Add new start state:

$S_0 \to S$
$S \to ASB$
$A \to aAS|a|\varepsilon$
$B \to SbS|A|bb$

Eliminate ε-rules

$A \to \varepsilon$:
$S_0 \to S$
$S \to ASB|SB$
$A \to aAS|a|aS$
$B \to SbS|A|bb|\varepsilon$

Eliminate $B \to \varepsilon$:
$S_0 \to S$
$S \to ASB|SB|S|AS$
$A \to aAS|a|aS$
$B \to SbS|A|bb$

Remove Unit rules:

$B \to A$:
$S_0 \to S$
$S \to ASB|SB|S|AS$
$A \to aAS|a|aS$
$B \to SbS|bb|aAS|a|aS$

$S \to S$:
$S_0 \to S$
$S_0 \to ASB|SB|AS$
$A \to aAS|a|aS$
$B \to SbS|bb|aAS|a|aS$

$S_0 \to S$:
$S_0 \to ASB|SB|AS$
$S \to ASB|SB|AS$
$A \to aAS|a|aS$
$B \to SbS|bb|aAS|a|aS$

Replace rules which have more than two symbols:

$S_0 \to ASB$: $S_0 \to AU_1$ and $U_1 \to SB$
$\therefore S_0 \to AU_1|SB|\,AS$
$S \to AU_1|SB|\,AS$
$A \to aAS|a|aS$
$B \to SbS|bb|aAS|a|aS$
$U_1 \to SB$

$A \to aAS \Rightarrow A \to aU_2$ and $U_2 \to AS$ and $B \to SbS$
$\Rightarrow B \to SU_3$ and $U_3 \to bS$
$\therefore S_0 \to AU_1|SB|AS$
$S \to AU_1|SB|\,AS$
$A \to aU_2|a|aS$
$B \to SU_3|bb|aU_2|a|aS$
$U_1 \to SB$
$U_2 \to AS$
$U_3 \to bS$

Eliminate rules which have terminals and variables or two terminals.

Let $V_1 \to a$, $V_2 \to b$
$\therefore S_0 \to AU_1|AS|SB$
$S \to AU_1|SB|AS$
$A \to V_1U_2|a|V_1S$

$B \rightarrow SU_3|V_2V_2|V_1U_2|a|V_1S$
$U_1 \rightarrow SB$
$U_2 \rightarrow AS$
$U_3 \rightarrow V_2S$
$V_1 \rightarrow a$
$V_2 \rightarrow b$
$\therefore$ Nine non-terminals.

Greiback Normal Form (GNF)

- A CFG, $G = (V, T, R, S)$ is said to be in GNF, if every production is of form $A \rightarrow a\alpha$ where $a \in T$, $\alpha \in V^*$, i.e., α is a string of zero or more variables.
- Left recursion in R can be eliminated by following schema: If $A \rightarrow A\alpha_1 |A\alpha_2| \ldots |A\alpha_r|\beta_1|\beta_2| \ldots |\beta_s$, then replace the above rules by
  (i) $A \rightarrow \beta_i|\beta_iZ$, $1 \leq i \leq s$
  (ii) $Z \rightarrow \alpha_i|\ \alpha_iZ$, $1 \leq i \leq r$
- If $G = (V, T, R, S)$ is a CFG, then another CFG, $G_1 = (V_1, T, R_1, S)$ can be constructed in GNF $\exists$ $L(G_1) = L(G) - \{\varepsilon\}$.

The step wise algorithm is as follows:

1. Eliminate null production, unit productions and useless symbols from the grammar G and then construct a $G^1 = (V^1, T, R^1, S)$ in CNF generating the language $L(G^1) = L(G) - \{\varepsilon\}$.
2. Rename the variables like $A_1, A_2, \ldots A_n$ starting with $S = A_1$.
3. Modify the rules in R^1, so that if $A_i \rightarrow A_j\gamma \in R^1$ then $j > i$.
4. Starting with A_1 and proceeding to A_n, can be obtained as:
   (a) Assume that productions have been modified so that for $1 \leq i \leq k$, $A_i \rightarrow A_j\gamma \in R^1$ only if $j > i$
   (b) If $A_k \rightarrow A_j\gamma$ is a production with $j < k$, generate a new set of productions substituting for A_j, the body of each A_j production.
   (c) Repeating (b) atmost $k - 1$ times, obtains rules of the form $A_k \rightarrow A_p\gamma$, $p \geq k$.
   (d) Replace rules $A_k \rightarrow A_k\gamma$ by removing left-recursion.
5. Modify the $A_i \rightarrow A_j\gamma$ for $i = n - 1, n - 2, \ldots 1$ in desired form at same time change z production rules.

Example 7: A grammar G is defined with rules $S \rightarrow XA|BB$, $B \rightarrow b|SB$, $X \rightarrow b$, $A \rightarrow a$. The normalized GNF of G contains ____ productions.

(A) 17 (B) 19
(C) 5 (D) 16

Solution: (B)

1. The Grammar, G is already in CNF.
2. Re-label with variables
   S with A_1
   X with A_2
   A with A_3
   B with A_4
   Grammar, G now is:
   $A_1 \rightarrow A_2A_3|A_4A_4$
   $A_4 \rightarrow b|A_1A_4$
   $A_2 \rightarrow b$
   $A_3 \rightarrow a$
3. Identify all productions which do not conform to any of the types listed below:
   $A_i \rightarrow A_j\, x_k \ \exists\, j > i$
   $Z_i \rightarrow A_j\, x_k \ \exists\, j \leq n$
   $A_i \rightarrow a\, x_k \ \exists\, x_k \in V^*$ and $a \in T$
4. $A_4 \rightarrow A_1\, A_4 \ldots$ identified
5. $A_4 \rightarrow A_1\, A_4|b$
   To eliminate A_1, use substitution rule, $A_1 \rightarrow A_2\, A_3|A_4A_4$
   $\therefore$ $A_4 \rightarrow A_2\, A_3\, A_4|A_4\, A_4A_4|b$
   Substitute $A_2 \rightarrow b$
   $\therefore$ $A_4 \rightarrow b\, A_3\, A_4|A_4\, A_4\, A_4|b$
   $A_4 \rightarrow A_4\, A_4\, A_4$ is left recursive. So, remove left recursion i.e., $A_4 \rightarrow b\, A_3\, A_4|b|bA_3A_4Z|bZ$
   $Z \rightarrow A_4A_4|A_4\, A_4Z$
6. Now, $G = A_1 \rightarrow A_2\, A_3|A_4A_4$
   $A_4 \rightarrow b\, A_3\, A_4|b|b\, A_3\, A_4\, Z|b\, Z$
   $Z \rightarrow A_4\, A_4|A_4\, A_4Z$
   $A_2 \rightarrow b$
   $A_3 \rightarrow a$
7. A_1, Z are not in GNF. So,
   For $A_1 \rightarrow A_2A_3|A_4A_4$:
   Substitute for A_2 and A_4 to convert it to GNF
   $A_1 \rightarrow b\, A_3|\ b\, A_3\, A_4\, A_4|b\, A_4|b\, A_3\, A_4\, Z\, A_4|b\, Z\, A_4$
   For $Z \rightarrow A_4\, A_4|A_4\, A_4\, Z$
   substitute for A_4 to convert it to GNF
   $Z \rightarrow b\, A_3\, A_4\, A_4|b\, A_4|b\, A_3\, A_4\, Z\, A_4|b\, Z\, A_4|b\, A_3\, A_4\, A_4\, Z|b\, A_4\, Z|b\, A_3\, A_4\, Z\, A_4\, Z|b\, Z\, A_4\, Z$
   $\therefore$ Final GNF is:
   $A_1 \rightarrow b\, A_3|b\, A_3\, A_4\, A_4|b\, A_4|\ b\, A_3\, A_4\, Z\, A_4|b\, Z\, A_4$
   $A_4 \rightarrow b\, A_3\, A_4|b|b\, A_3\, A_4\, Z|b\, Z$
   $A_2 \rightarrow b$
   $A_3 \rightarrow a$
   $Z \rightarrow b\, A_3\, A_4\, A_4|b\, A_4|b\, A_3\, A_4\, Z\, A_4|b\, Z\, A_4|b\, A_3\, A_4\, A_4\, Z|\ b\, A_4\, Z|b\, A_3\, A_4\, Z\, A_4\, Z|b\, Z\, A_4\, Z$
   $\therefore$ 19 productions.

Pumping Lemma for Context Free Languages

Let 'L' be context free language. There exists some integer, m $\exists$ $\forall$w in L, with $|w| \geq m$, $w = uvxyz$ with $|vxy| \leq m$ and $|vy| \geq 1$ $\exists$ $u\, v^i\, x\, y^i\, z \in L$ $\forall$ $i = 0, 1, 2, 3, \ldots$

Note: Pumping lemma is used to show that a language is Not context free.

Example 8: The language $\{a^n\, b^m\, c^n\, d^{(n+m)}: m, n \geq 0\}$ is

(A) Regular
(B) Context free but not regular
(C) Neither context free nor regular
(D) Cannot be determined

Solution: (C)

$L = \{a^n b^m c^n d^{(n+m)}: m, n \geq 0\}$

Clearly, L is not regular because, number of a's and number of b's must be known to compute number of d's.

'L' is not context free because, Let $w = a^M b^M c^M d^{2M}$. Clearly neither v nor y can cross regions and include more than one letter, since if that happened; letters obtained will be out of order when pumped.

So, consider cases, where v and y fall within a single region. Consider 4-regions corresponding to a, b, c and d.

(1, 1) $\rightarrow$ change number of a's and they won't match c's any more.

(1, 2) $\rightarrow$ If v is not empty, change a's and they won't match with c's. If y is non-empty, number of b's changed won't have right number of d's.

(1, 3), (1, 4) $\rightarrow$ ruled out. $\because$ $|v\,x\,y| \leq M$

(2, 2) $\rightarrow$ Change number of b's and they won't match right number of d's.

(2, 3) $\rightarrow$ If v is non-empty, change number of b's without changing number of d's. If y is not empty, change c's and they'll no longer match a's.

(2, 4) $\rightarrow$ ruled out $\because$ $|v\,x\,y| \leq M$

(3, 3) $\rightarrow$ Change number of c's and they won't match a's.

(3, 4) $\rightarrow$ If v is not empty change c's and they won't match a's. If y is not empty, change d's without changing b's.

(4, 4) $\rightarrow$ change d's without changing a's or b's.

$\therefore$ L is not context free.

Closure Properties of CFL's

1. **CFL's are closed under union:** For CFL's L_1, L_2 with CFG's G_1, G_2 and start variables S_1, S_2. The grammar of Union $L_1 \cup L_2$ has new start symbol S and additional production $S \rightarrow S_1 | S_2$
2. **CFL's are closed under concatenation:** For CFL's L_1, L_2 with CFG's G_1, G_2 and start variables S_1, S_2. The grammar of concatenation L_1L_2 has new start variables S and additional production: $S \rightarrow S_1\, S_2$
3. **CFL's are closed under star operation:** For CFL L, with CFG G and start variable S. The grammar of the start operation L^* has new start variable S_1 and additional production:

$$S_1 \rightarrow S\, S_1 | \varepsilon$$

4. **CFL's are not closed under intersection:** If L_1, L_2 are two context free languages, $L_1 \cap L_2$ not necessarily be context free.
5. **CFL's are not closed under complement:** If L is context free language, $\overline{L}$ not necessarily be context free.
6. **Intersection of CFL's and regular language: (regular closure):** If L_1 is a CFL and R_2 is a regular language then $L_1 \cap L_2$ is a CFL.

Example 9: The language, $L_1 = \{a^n\, b^n : n \geq 0\}$ and $L_2 = \{a^{100}\, b^{100}\}$. The relation $L_1 \cap \overline{L_2}$ is ______

(A) Regular
(B) Context free
(C) Regular but not context fee
(D) Cannot be determined

Solution: (B)

$L_1 = \{a^n\, b^n : n > 0\}$ is context free

$L_2 = \{a^{100}\, b^{100}\}$ is regular

$\overline{L_2} = \{(a+b)^*\} - \{a^{100}b^{100}\}$ is regular

$\{a^n\, b^n\}$ context free

$\overline{L_2} = \{(a+b)^*\} - \{a^{100}b^{100}\}$ is regular

$\{a^n b^n\} \cap \overline{L_2}$ $\rightarrow$ context free

$\{a^n b^n\} \cap \overline{L_2} = \{a^n b^n : n \neq 100,\ n \geq 0\} = L$ is context free:

Table 1 *Comparing Regular and Context free Languages:*

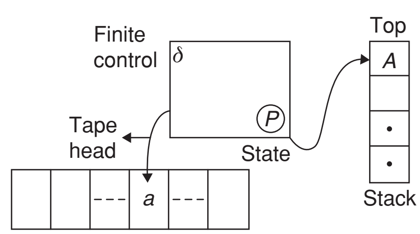
Regular Language	CFL
Regular expression or regular grammar	Context free grammar
Recognize the language	Parses the language
These are DFSA's	These are NDPDA's
Minimize FSA's	Find deterministic grammar.
Closed under: Concatenation Union Kleen star Complement Intersection	Closed under: Concatenation Union Kleen star

Push Down Automata (PDA)

A push down automata is merely a finite automata with a stack added to it.

PDA is used to generate context free language.

The stack allows for unbounded memorization.



Input tape: The tape is divided into finitely many cells. Each cell contains a symbol in an alphabet, Σ.

Stack: The stack head always scans the top symbol of the stack. It performs two basic operations.

- Push: Add a new symbol at the top
- Pop: Read and remove the top symbol

Tape head: The head scans at a cell on the tape and can read a symbol on the cell. In each move, the head can move to the right cell.

Finite control: The finite control has finitely many states which form a set Q. For each move, the state is changed according to the evaluation of transition function.

A PDA is defined as: $P = (Q, \Sigma, \Gamma, \delta, q_0, z_0, F)$

Where Q: set of States

Σ: Input alphabet

Γ: Stack symbol

δ: Transition function

q_0: Start state

z_0: Initial stack top symbol

F: Final/accepting states

Transition functions δ: $Q \times \Gamma \times \Sigma \Rightarrow Q \times \Gamma$

Q: Old state

Γ: Stack top

Σ: Input symbol

Q: New state, Γ: New stack top

PDA's instantaneous description (IDs): A PDA has a configuration at any given instance: (q, w, y)

$q \rightarrow$ current state

$w \rightarrow$ remainder of input (i.e., unconsumed part)

$y \rightarrow$ current stack contents as a string from top to bottom of the stack.

If $\delta(q, a, x) = \{P, A\}$ is a transition, then following are also true:

- $(q, a, x) \vdash (P, \varepsilon, A)$
- $(q, aw, xB) \vdash (p, w, AB)$

Note: 1. $\rightarrow$: Turnstile notation and represents one move.

2. $\vdash^*$: represents sequence of moves.

Principles about IDs:

1. If for a PDA, $(q, x, A) \vdash^* (p, y, B)$, then for any string $w \in \Sigma^*$ and $\gamma \in \Gamma^*$, it is also true that: $(q, xw, A\gamma) \vdash^* (p, yw, B\gamma)$
2. If for a PDA, $(q, xw, A) \vdash^* (p, yw, B)$, then it is also true that: $(q, x, A) \vdash^* (p, y, B)$

Acceptance by PDA: There are two types of PDAs that one can design:

- Those that accept by final state or
- Those that accept by empty stack

PDAs that accept by final state: For a PDA, P, the language accepted by P, denoted by $L(P)$ by final state, is:

$$\{w | (q_0, w, z_0) \vdash^* (q, \in, A)\} \exists q \in F$$

PDAs that accept by empty stack: For a PDA P, the language accepted by P, denoted by $N(P)$ by empty stack, is:

$$\{w | (q_0, w, z_0) \vdash^* (q, \varepsilon, \varepsilon)\}, \text{ for any } q \in Q.$$

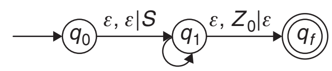
Example 10: Consider the grammar $S \rightarrow aTb | b, T \rightarrow Ta | \varepsilon$. The PDA constructed contains _____ states.

(A) 4 (B) 3 (C) 5 (D) 2

Solution: (B)

$S \rightarrow aTb|b$

$T \rightarrow Ta|\varepsilon$



$\varepsilon, S|aTb$

$\varepsilon, T|Ta$

$\varepsilon, S|b$

$\varepsilon, T|\varepsilon$

$a, a|\varepsilon$

$b, b|\varepsilon$

Let $S \rightarrow q_0, T \rightarrow q_1$

Consider string "aab" $S \rightarrow aTb \rightarrow aTab \rightarrow aab$

$\delta(q_0, aab, z_0) \vdash \delta(q_0, \varepsilon\, aab, z_0)$

$\vdash \delta(q_1, aab, q_0 z_0)$

$\vdash \delta(q_1, aab, aTb\, z_0)$

$\vdash \delta(q_1, ab, Tbz_0)$

$\vdash \delta(q_1, ab, aTbz_0)$

$\vdash \delta(q_1, b, Tbz_0)$

$\vdash \delta(q_1, b, \in bz_0)$

$\vdash \delta(q_1, b, bz_0)$

$\vdash \delta(q_1, \in, z_0)$

$\vdash \delta(q_f, \in) \rightarrow$ acceptance

PDAs accepting by final state and empty stack are equivalent:

$P_F \rightarrow$ PDA accepting by final state,

$P_F = (Q_F, \Sigma, \Gamma, \delta_F, q_0, z_0, F)$

$P_N \rightarrow$ PDA accepting by empty stack

$P_N = (Q_N, \Sigma, \Gamma, \delta_N, q_0, z_0)$

- For every P_N, $\exists P_F \exists L(P_F) = L(P_N)$
- For every P_F, $\exists P_N \exists L(P_N) = L(P_F)$

Converting CFG to PDA

The PDA simulates the left most derivation on a given w, and upon consuming it fully it either arrives at acceptance (by empty stack) or non-acceptance.

The steps to convert CFG to PDA are:

1. Push right hand side of the production on to stack, with left most symbol at the stack top.
2. If stack top is the left most variable, then replace it by all its productions (each possible substitution will represent a distinct path taken by non-deterministic PDA (NPDA).
3. If stack top has a terminal symbol and if it matches with the next symbol in the input string, then pop it. Follow from step-1 again to complete all productions.

Example 11: The CFG, G of a language L is $S \rightarrow AB$, $A \rightarrow aAb|\varepsilon$, $B \rightarrow cB/\varepsilon$. The PDA generated by G contains _____ states.

(A) 5 (B) 4 (C) 3 (D) 1

Solution: (C)

$S \rightarrow AB$
$A \rightarrow aAb|\varepsilon$
$B \rightarrow cB|\varepsilon$
$\Rightarrow \delta(q_0, w, S) = (q_1, AB)$
$\delta(q_1, w, A) = (q_1, aAb)$
$\delta(q_1, \varepsilon, A) = \delta(q_1, \varepsilon)$
$\delta(q_1, w, B) = (q_1, cB)$
$\delta(q_1, \varepsilon, B) = \delta(q_2, \varepsilon) \rightarrow$ accept
$\therefore$ $\{q_0, q_1, q_2\}$ 3-states.

Converting a PDA into a CFG

Given: $G = (V, T, P, S)$ Initial stack symbol (S) same as start variable in grammar
Output: $P_N = (\{q\}, T, V \cup T, \delta, q, S)$, where δ is

- If q_0 is start state in PDA and q_n is final state of PDA then $[q_0, z, q_n]$ becomes a start state of CFG. Here z represents stack symbol.
- The production rule for the ID of the form $\delta(q_i, a, z_0) = (q_{i+1}, z_1, z_2)$ can be obtained as:

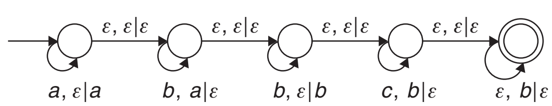
$$\delta(q_i, z_0, q_{i+k}) \rightarrow a(q_{i+1}, z_1, q_m)\ (q_m, z_2, q_{i+k})$$

Where q_{i+k}, q_m represents the intermediate staes, z_0, z_1, z_2 are stack symbols and a is input symbol.

- The production rule for the ID of the form $\delta(q_i, a, z_0) = (q_{i+1}, \varepsilon)$ can be converted as

$$(q_i, z_0, q_{i+1}) \rightarrow a$$

Example 12: The PDA, P for language L is generated as:



The CFG for P is:

(A) $S \rightarrow S_1S_2$
$S_1 \rightarrow aS_2b$
$S_2 \rightarrow c|\varepsilon$
(B) $S \rightarrow S_1bc$
$S_1 \rightarrow a|\varepsilon$
(C) $S \rightarrow S_1S_2$
$S_1 \rightarrow aS_1b|\varepsilon$
$S_2 \rightarrow bS_2|bS_2c|\varepsilon$
(D) $S \rightarrow aS_1c$
$S_1 \rightarrow b|\varepsilon$

Solution: (C)
The language, L generated by given PDA is

$$L = \{a^n\, b^n\, b^m\, c^p : m \geq p \text{ and } n, p \geq 0\}$$

It can be generated by following rules:

$$S \rightarrow S_1S_2$$

$S_1 \rightarrow aS_1b|\varepsilon \rightarrow S_1$ generates $a^n\, b^n$
$S_2 \rightarrow bS_2|bS_2c|\varepsilon \rightarrow S_2$ generates $b^m\, c^p$

Deterministic PDA (Deterministic CFL)

$$\left\{\begin{array}{c}\text{Deterministic}\\ \text{context free}\\ \text{languages}\\ \text{(DPDA)}\end{array}\right\} \subseteq \left\{\begin{array}{c}\text{Context-free}\\ \text{Languages}\\ \text{PDAs}\end{array}\right\}$$

- Every DPDA is also a PDA.
- A context free language 'L' accepted by PDA may or may not be accepted by DPDA.

A PDA, $M = (Q, \Sigma, \Gamma, \delta, q_0, F)$ is deterministic if there is no configuration for which M has choice of more than one move. That is, it must satisfy the following conditions:

1. For any $q \in Q$, $a \in \Sigma\varepsilon$ and $s \in \Gamma\, \varepsilon$, the set $\delta(q, a, s)$ has almost one element. (Doesn't allow two or more transitions from same state).
2. For any $q \in Q$, and $s \in \Gamma\varepsilon$, if $\delta(q, \varepsilon, s) \neq \phi$, then $\delta(q, a, s) = \phi$ for every $a \in \Sigma$ and $\delta(q, a, \varepsilon) = \phi$ for all $a \in \Sigma\varepsilon$.
3. For any $q \in$ Q and $a \in \Sigma$, if $(q, a, \varepsilon) \neq \phi$, then $\delta(q, a, s) = \phi$ for all $s \in \Gamma$ and $\delta(q, \varepsilon, t) = \phi$ for all $t \in \Gamma_{\varepsilon.}$
4. For any $q \in Q$, if $\delta(q, \varepsilon, \varepsilon) \neq \phi$, then $\delta(q, a, t) = \phi$ for all $a \in \Sigma\varepsilon$ and $t \in \Gamma_\varepsilon$ (except when $a = \varepsilon$, $t = \varepsilon$).

Rule-2 says that if there is a transition from state q that reads character, s from stack but doesn't read other input, other transitions from q, that don't read stack are not allowed and other transitions from q that read s from the stack and read the input are not allowed either.

Rule-3 says that if there is a transition from state q that reads character a, but doesn't read stack, other transitions from q that don't read the input are not allowed and other transitions from q that read 'a' from input and read the stack are not allowed either.

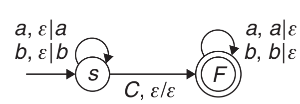
Rule-4 says that if there is a transition from q that doesn't read either input or stack, all other transitions from q are not allowed.

Example 13: A language, L is defined as: $L = \{wcw^R : w \in (a, b)^*\}$. What is Nature of language L?

(A) CFL and DCFL (B) Only CFL
(C) Only DCFL (D) None of these

Solution: (A)

$$L = \{x = wcw^R \text{ for } w \in (a, b)^*\}$$



Clearly, obtained PDA is also DPDA in sense; there is no choice in transitions.

$\therefore$ Hence L is CFL and DCFL.

Exercises

Practice Problems 1

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Consider the grammar, $G = (V, \Sigma, R, S)$ where $V = \{a, b, S, A\}$, $\Sigma = \{a, b\}$, $R = \{S \to AA, A \to AAA, A \to a, A \to bA, A \to Ab\}$ How many strings can be generated by $L(G)$ that can be produced by derivations of four or fewer steps?

(A) 5 (B) 10 (C) 14 (D) 8

2. Consider the following languages L_1, L_2 and L_3:

$L_1 = \{a^n b^m c^{n+m} | n, m \geq 0\}$

$L_2 = \{a^n b^{n+1} c^{n+2} | n \geq 0\}$

$L_3 = \{a^n b^n c^m | n, m \geq 0\}$

Which of following statement is true?

(A) L_1, L_2, L_3 are context free languages
(B) L_1, L_2 are context free but not L_3
(C) L_1, L_3 are context free but not L_2
(D) L_1, L_2, L_3 are not context free languages.

3. The language, $L = \{b_i \# b_{i+1} : b_i$ is i in binary, $i \geq 1\}$ is:

(A) Regular
(B) Context free
(C) Regular and context free
(D) Neither context free nor Regular

4. The CFG, $G : A \to BAB|B|\varepsilon$, $B \to 00|\varepsilon$. The CFG is normalized using CNF. The obtained G', contains ___ rules.

(A) 11 (B) 14 (C) 12 (D) 13

5. The language $L = \{0^{2^i} : i \geq 1\}$ is:

(A) Context free
(B) DCFL
(C) Both CFL and DCFL
(D) Not context free language

6. The context free grammar, G is defined with production rules $S \to EcC'|aAE|AU$, $A \to aA|\varepsilon$, $B \to bB|\varepsilon$, $C' \to cC'|\varepsilon$, $E \to aEc|F$, $F \to bFc|\varepsilon$, $U \to aUc|V$, $V \to bVc|bB$ What is the language generated by L?

(A) $L = \{a^n b^m c^k : k \neq n + m\}$
(B) $L = \{a^n b^m c^k : k = n + m\}$
(C) $L = \{a^n b^m c^k : k > n + m\}$
(D) $L = \{a^n b^m c^k : k < n + m\}$

7. Consider the grammar, $G \equiv S \to abScB|\varepsilon$, $B \to bB|b$. What language does it generate?

(A) $L(G) = \{(ab)^n (cb)^m | n = m\}$
(B) $L(G) = \{a^n b^n (cb)^m | n \neq m\}$
(C) $L(G) = \{(ab)^n (cb^m)^n | n \geq 0, m > 0\}$
(D) $L(G) = \{\{ab)^n (cb^m)^n | n \geq 0, m \geq 0\}$

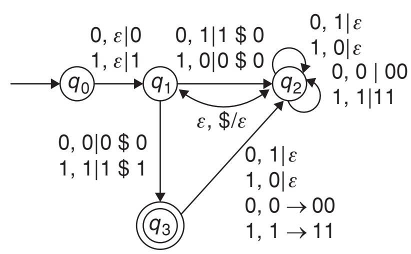
8. The language, $L = \{0^i 1^j 2^k | i \neq j$ or $j \neq k\}$. The CFG, G generated by L contains ___ rules.

(A) 23 (B) 20
(C) 21 (D) 19

9. The DPDA constructed to accept language, L with property $L = L_1 \cup L_2$ where $L_1 = \{10^n 1^n | n > 0\}$, $L_2 = \{110^n 1^{2n} | n > 0\}$ contains ___ states.

(A) 4 (B) 5
(C) 6 (D) 7

10. The PDA is designed as:



What is the language generated by the above PDA?

(A) Binary strings that have same number of 0's and 1's.
(B) Binary strings that start with 00 and end with 11 and have same number of 0's and 1's.
(C) Binary strings that start and end with the same symbol and have same number of 0's and 1's.
(D) Binary strings that start with 11 and end with 00 and have same number of 0's and 1's.

11. The language, $L = (ba^{m_1}ba^{m_2}b \cdots ba^{m_n} : n \geq 2, m_1, \ldots m_n \geq 0$ and $m_i \neq m_j$ for some $i, j)$. What is nature of 'L'?

(A) Regular
(B) Context free but not regular
(C) Regular but not context free
(D) Neither context free nor regular

12. Two languages L_1, L_2 are defined as:

$L_1 = \{a^i b^j c^k : i, j, k \geq 0, i = j\}$

$L_2 = \{a^i b^j c^k : i, j, k \geq 0, j = k\}$ which of following statements are true?

(i) $L_1 \cap L_2$ is context free
(ii) $L_1 \cap L_2 = \{a^n b^n c^n | n \geq 0\}$
(iii) L_1, L_2 are context free
(iv) Only L_1 is context free

(A) All are true (B) (i), (ii) are true
(C) (iii), (iv) are true (D) (ii), (iii) are true

13. The language generated by grammar:

$S \to Te|Ue$, $T \to cTd|cT|\varepsilon$, $U \to cUd|Ud|dd$. is

(A) $L = \{c^n d^m e : m \geq n\}$
(B) $L = \{c^n d^m e : m = n\}$
(C) $L = \{c^m d^n e^m : m \geq n + 2\}$
(D) None of these

14. Remove null productions, useless symbols from the following grammar result in:

$S \to ABC$

$A \to aBC$

$B \to C|\varepsilon$

$C \to cd|DCF$

$D \to dD|\varepsilon$

$E \to eFE$
$F \to eC$

(A) $S \to ABC|AC$
$A \to aBC|aC$
$B \to C$
$C \to cd|DCF|CF$
$D \to dD|d$
$F \to eC$

(B) $S \to aBCc$
$A \to aBC$
$B \to cD|dDEF|dEF$
$C \to cD|dDEF|dEF$
$F \to eB$
$D \to dD|d$
$E \to eFE|e$

(C) $S \to aBCBC|aBC$
$B \to cD|dDEF|dEF$
$F \to eB$
$C \to dD|d$
$D \to e$
$F \to CD|dDEF$

(D) None of these

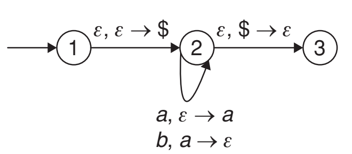
15. Let the language L_1, L_2 are defined as: L_1: $\{a^i\ b^{2i}\ c^j |\ i, j \geq 0\}$, $L_2 = \{a^i\ b^{2i}\ a^i |\ i \geq 0\}$. Which of following is true?
(A) L_1, L_2 are context free
(B) Only L_1 is context free
(C) Only L_2 is context free
(D) Neither L_1 nor L_2 is context free

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Consider the alphabet $\Sigma = \{a, b, c, (,), \cup, ^*, \phi\}$. Then context free grammar that generates all strings in Σ^* that are regular expressions over $\{a, b\}$ is:
(A) $S \to S^*|a|b|SS$
(B) $S \to \phi|a|b|S$
(C) $S \to \phi|a \cup b|S^*$
(D) $S \to \phi|S^*|a|b|(S)|S \cup S|SS$

2. The PDA for language, L is designed below. The CFG generated contains _____ productions.



(A) 5 (B) 4
(C) 3 (D) 6

3. The language, L generated by the following grammar, $S \to SS|\ AAA|\varepsilon$, $A \to aA|\ Aa|\ b$ is
(A) $(a^*\ b^*)^*$ (B) $(a^*\ b^*\ b^*\ a^*)^*$
(C) $a^*\ b^*\ a^*$ (D) $(a^*\ b\ a^*\ b\ a^*\ b\ a^*)^*$

4. The grammar, G is defined with rules $S \to S_1|S_2$, $S_1 \to S_1b|Ab|\varepsilon$, $A \to aAb|\ ab$, $S_2 \to S_2a|\ Ba|\varepsilon$, $B \to bBa|\ ba$. The CNF is applied on G. The obtained grammar, G' contains ____ rules.
(A) 24 (B) 23
(C) 21 (D) 20

5. The language, $L = \{b^{n^2} : n \geq 1\}$ is:
(A) CFL but not DCFL
(B) DCFL but not CFL
(C) Only DCFL
(D) Not CFL

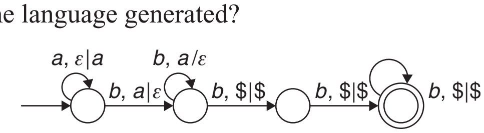
6. Consider the grammar, $G = S \to aSc|B$, $B \to bBc|\varepsilon$ The language, L generated by G is
(A) $L = \{a^n\ b^m\ c^k: k = n + m\}$
(B) $L = \{a^n\ b^m\ c^k: k \neq n + m\}$
(C) $L = \{a^n\ b^m\ c^k: k > n + m\}$
(D) $L = \{a^n\ b^m\ c^k: k < n + m\}$

7. The grammar, G is defined with productions: $S \to 0A|1B$, $A \to 0AA|1S|1$, $B \to 1BB|0S|0$
The grammar, G_2 is defined with productions: $S \to AB|aaB$, $A \to a|Aa$, $B \to b$
Which grammar is/are ambiguous?
(A) Only G_1
(B) Only G_2
(C) Both G_1 and G_2
(D) Both G_1 and G_2 are unambiguous

8. The language, $L_1 = \{0^n\ 1^n |\ n > 0\}$ and $L_2 = \{0^n\ 1^{2n} |\ n > 0\}$. The CFG generated for $L_1 \cup L_2$ is:
(A) $S \to 0\ A\ 1|0\ A\ 1\ 1$
$A \to 0|1|\varepsilon$
(B) $S \to 0\ A\ 1\ 1$
$A \to 0|1|\varepsilon$
(C) $S \to 0\ A\ 1|0\ B\ 1\ 1$
$A \to 0\ A\ 1|\varepsilon$
$B \to 0\ B\ 1\ 1|\varepsilon$
(D) $S \to 0\ A\ 1\ 1|0\ 1\ 1$
$A \to 0|1|\varepsilon$

9. The NPDA constructed to accept language, L with property, $L = L_1 \cup L_2$, where $L_1 = \{1^n\ 0^n |\ n > 0\}$, $L_2 = \{0^n\ 1^{2n} |\ n \geq 0\}$ contains _____ final states.
(A) 3 (B) 1
(C) 2 (D) 4

10. The DPDA for language, L is designed below. What is the language generated?



(A) $L = \{a^n b^m : m = n\}$
(B) $L = \{a^n b^m : m = n + 2\}$
(C) $L = \{a^n b^m : m \geq n + 2\}$
(D) $L = \{a^n b^m : m \leq n + 2\}$

11. The CFG, G is defined with rules: $S \to AB|CD$, $A \to A00|\varepsilon$, $B \to B11|1$, $C \to C00|0$, $D \to D11|\varepsilon$. The language generated by G is
(A) $L = \{0^n\ 1^n | n \geq 0\}$
(B) $L = \{0\ 0^n\ 1\ 1^n | n > 0\}$
(C) $L = \{0^n\ 1^m | n + m \text{ is odd}\}$
(D) $L = \{0^n\ 1^m | n + m \text{ is even}\}$

12. The languages, L_1, L_2, L_3 are defined as: $L_1 = \{a^n\ b^m\ c^{n+m} | n, m \geq 0\}$, $L_2 = \{a^n\ b^n\ c^m | n, m \geq 0\}$, $L_3 = \{a^n\ b^n\ c^{2n} | n \geq 0\}$, Which of the following statements are true?
(i) L_1, L_2 are context free
(ii) L_1, L_3 are context free
(iii) $L_3 = L_1 \cap L_2$
(iv) L_1, L_3 are context free but not L_2
(A) (i), (ii) (B) (i), (iii)
(C) (ii), (iii) (D) (iii), (iv)

13. The language, L_1 and L_2 are defined as $L_1 = \{a^n\ b^n : n \geq 0$ and n is not a multiple of $5\}$ and $L_2 = \{0^n \# 0^{2n} \# 0^{3n} | n \geq 0\}$. Which of following is true?
(A) L_1 and L_2 are context free
(B) Only L_1 is context free
(C) Only L_2 is context free
(D) Neither L_1 nor L_2 is context free

14. The language, L_1 and L_2 are defined as $\overline{L_1} = \{(0^n 1^n)^m | m, n > 0\}$, $L_2 = \{0^n\ 1^n\ 0^n\ 1^n | n \geq 0\}$ which of following is true?
(A) L_1 and L_2 are context free
(B) Only $\overline{L_1}$ is context free
(C) Only L_2 is context free
(D) Neither L_1 nor L_2 is context free

15. The language L_1, L_2 are defined as $L_1 = \{0^i\ 1^i\ 0^j\ 1^j | i, j > 0\}$, $L_2 = \{1^k\ 0^i\ 1^i\ 0^j\ 1^j\ 0^k | i, j, k > 0\}$. Which of following is true?
(A) L_1 and L_2 are context free
(B) Only L_1 is context free
(C) Only L_2 is context free
(D) Neither L_1 nor L_2 is context free

Previous Years' Questions

1. Match the following: **[2008]**

E. Checking that identifiers are declared before their use	P. $L = \{a^n b^m c^n d^m | n \geq 1, m \geq 1\}$
F. Number of formal parameters in the declaration of a function agrees with the number of actual parameters in use of that function	Q. $X \to XbX|XcX|dXf|g$
G. Arithmetic expressions with matched pairs of parentheses	R. $L = \{wcw | w \in (a|b)^*\}$
H. Palindromes	S. $X \to bXb|cXc|\varepsilon$

(A) E − P, F − R, G − Q, H − S
(B) E − R, F − P, G − S, H − Q
(C) E − R, F − P, G − Q, H − S
(D) E − P, F − R, G − S, H − Q

2. Consider the languages L_1, L_2 and L_3 as given below.
$L_1 = \{0^p\ 1^q | p, q \in N\}$,
$L_2 = \{0^p\ 1^q | p, q \in N \text{ and } p = q\}$ and
$L_3 = \{0^p\ 1^q\ 0^r | p, q, r \in N \text{ and } p = q = r\}$. Which of the following statements is NOT TRUE? **[2011]**
(A) Push Down Automata (PDA) can be used to recognize L_1 and L_2.
(B) L_1 is a regular language.
(C) All the three languages are context free
(D) Turing machines can be used to recognize all the languages.

3. Which of the following problems are decidable? **[2012]**
(1) Does a given program ever produce an output?
(2) If L is a context free language, then, is $\overline{L}$ also context free?
(3) If L is a regular language, then, is $\overline{L}$ also regular?
(4) If L is recursive language, then, is $\overline{L}$ also recursive?
(A) 1, 2, 3, 4 (B) 1, 2
(C) 2, 3, 4 (D) 3, 4

4. Consider the following languages.
$L_1 = \{0^p\ 1^q\ 0^r | p, q, r \geq 0\}$
$L_2 = \{0^p\ 1^q\ 0^r | p, q, r \geq 0, p \neq r\}$
Which one of the following statements is **FALSE**? **[2013]**
(A) L_2 is context-free
(B) $L_1 \cap L_2$ is context-free
(C) Complement of L_2 is recursive
(D) Complement of L_1 is context-free but not regular

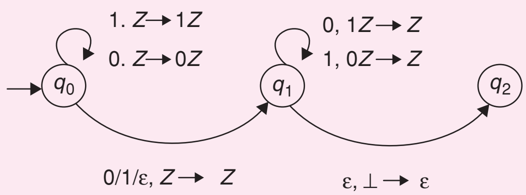
5. Which one of the following is **TRUE**? **[2014]**
(A) The language $L = \{a^n\ b^n | n \geq 0\}$ is regular
(B) The language $L = \{a^n | n \text{ is prime}\}$ is regular
(C) The language $L = \{w | w$ has $3k + 1b$'s for some $k \in N$ with $\Sigma = \{a, b\}\}$ is regular
(D) The language $L = \{ww | w \in \Sigma^*$ with $\Sigma = \{0, 1\}\}$ is regular.

6. Consider the following languages over the alphabet $\Sigma = \{0, 1, c\}$.
$L_1 = \{0^n\ 1^n | n \geq 0\}$
$L_2 = \{wcw^r | w \in \{0, 1\}^*\}$
$L_3 = \{ww^r | w \in \{0, 1\}^*\}$

Here w^r is reverse of the string w. Which of these languages are deterministic context-free languages? **[2014]**

(A) None of the languages
(B) Only L_1
(C) Only L_1 and L_2
(D) All the three languages

7. Consider the NPDA $<Q = \{q_0, q_1, q_2\}, \Sigma = \{0, 1\}, \Gamma = \{0, 1, \perp\}, \delta, q_0, \perp, F = \{q_2\}>$, where (as per usual convention) Q is the set of states, Σ is the input alphabet, Γ is the stack alphabet, δ is the state transition function, q_0 is the initial state, $\perp$ is the initial stack symbol, and F is the set of accepting states. The state transition is as follows:



Which one of the following sequences must follow the string 1011 00 so that the overall string is accepted by the automation? **[2015]**

(A) 10110 (B) 10010
(C) 01010 (D) 01001

8. Which of the following languages are context-free? **[2015]**

$L_1 = \{a^m b^n a^n b^m \mid m, n \geq 1\}$
$L_2 = \{a^m b^n a^m b^n \mid m, n \geq 1\}$
$L_3 = \{a^m b^n \mid m = 2n + 1\}$

(A) L_1 and L_2 only (B) L_1 and L_3 only
(C) L_2 and L_3 only (D) L_3 only

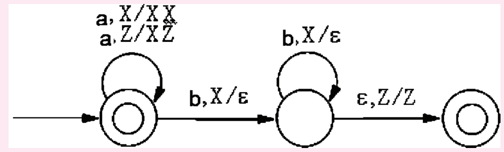
9. Consider the following context-free grammars:

G_1: $S \rightarrow aS|B$, $B \rightarrow b|bB$
G_2: $S \rightarrow aA|bB$, $A \rightarrow aA|B|$ ε, B $|bB$ε

Which one of the following pairs of languages is generated by G_1 and G_2, respectively? **[2016]**

(A) $\{a^m b^n \mid m > 0$ or $n > 0\}$ and $\{a^m b^n \mid m > 0$ and $n > 0\}$
(B) $\{a^m b^n \mid m >$ 0and $n > 0\}$ and $\{a^m b^n \mid m > 0$ or $n \geq 0\}$
(C) $\{a^m b^n \mid m \geq 0$ or $n > 0\}$ and $\{a^m b^n \mid m > 0$ and $n > 0\}$
(D) $\{a^m b^n \mid m \geq 0$ and $n > 0\}$ and $\{a^m b^n \mid m > 0$ or $n > 0\}$

10. Consider the transition diagram of a PDA given below with input alphabet $\Sigma = \{a, b\}$ and stack alphabet $= \{X,Z\}$. Z is the initial stack symbol. Let L denote the language accepted by the PDA.



Which one of the following is TRUE? **[2016]**

(A) $L = \{a^n b^n \mid n \geq 0\}$ and is not accepted by any finite automata.
(B) $L = \{a^n \mid n \geq 0) \cup \{a^n b^n \mid n \geq 0\}$ and is not accepted by any deterministic PDA.
(C) L is not accepted by any Turing machine that halts on every input.
(D) $L = \{a^n | n \geq 0\} \cup \{a^n b^n | n \geq 0\}$ and is deterministic context-free.

11. Consider the following languages:

$L_1 = \{a^n b^m c^{n+m} : m, n \geq 1\}$
$L_2 = \{a^n b^n c^{2n} : n \geq 1\}$

Which one of the following is TRUE? **[2016]**

(A) Both L_1 and L_2 are context - free.
(B) L_1 is context - free while L_2 is not context - free
(C) L_2 is context - free while L_1 is not context - free.
(D) Neither L_1 nor L_2 is context - free.

12. Consider the following context-free grammar over the alphabet $\Sigma = \{a, b, c\}$ with S as the start symbol:

$S \rightarrow abScT \mid abcT$
$T \rightarrow bT \mid b$

Which one of the following represents the language generated by the above grammar? **[2017]**

(A) $\{(ab)^n(cb)^n \mid n \geq 1\}$
(B) $\{(ab)^n cb^{m_1} cb^{m_2} \ldots cb^{m_n} \mid n, m_1, m_2, \ldots, m_n \geq 1\}$
(C) $\{(ab)^n(cb^m)^n \mid m, n \geq 1\}$
(D) $\{(ab)^n(cb^n)^m \mid m, n \geq 1\}$

13. If G is a grammar with productions

$$S \rightarrow SaS \mid aSb \mid bSa \mid SS \mid \in$$

Where S is the start variable, then which one of the following strings is not generated by G? **[2017]**

(A) *abab* (B) *aaab*
(C) *abbaa* (D) *babba*

14. Consider the context-free rammers over the alphabet $\{a, b, c\}$ given below. S and T are non-terminals.

$$G_1: S \rightarrow aSb|T, T \rightarrow cT|\in$$
$$G_2: S \rightarrow bSa|T, T \rightarrow cT|\in$$

The language $L(G_1) \cap L(G_2)$ is **[2017]**

(A) Finite
(B) Not finite but regular
(C) Context-Free but not regular
(D) Recursive but not context-free.

15. Consider the following languages over the alphabet $\Sigma = \{a, b, c\}$.

Let $L_1 = \{a^n b^n c^m | m, n \geq 0\}$ and $L_2 = \{a^m b^n c^n | m, n \geq 0\}$. Which of the following are context-free languages? **[2017]**

I. $L_1 \cup L_2$
II. $L_1 \cap L_2$

(A) I only (B) II only
(C) I and II (D) Neither I nor II

16. Let L_1, L_2 be any two context-free languages and R be any regular language. Then which of the following is/are CORRECT? **[2017]**

I. $L_1 \cup L_2$ is context-free.
II. $\overline{L_1}$ is context-free.
III. $L_1 - R$ is context-free.
IV. $L_1 \cap L_2$ is context-free.

(A) I, II and IV only (B) I and III only
(C) II and IV only (D) I only

17. Identify the language generated by the following grammar, where S is the start variable. **[2017]**

$$S \to XY$$
$$X \to aX|a$$
$$Y \to aYb|\in$$

(A) $\{a^m b^n | m \geq n, n > 0\}$ (B) $\{a^m b^n | m \geq n, n \geq 0\}$
(C) $\{a^m b^n | m > n, n \geq 0\}$ (D) $\{a^m b^n | m > n, n > 0\}$

18. Consider the following languages.

$L_t = \{a^p \mid p \text{ is a prime number}\}$
$L_2 = \{a^n b^m c^{2m} | n \geq 0, m \geq 0\}$
$L_3 = \{a^n b^n c^{2n} | n \geq 0\}$
$L_4 = \{a^n b^n \mid n \geq 1\}$

Winch of the following are CORRECT? **[2017]**

I. L_1 is context-free but not regular.
II. $L_2$is not context-free.
III. $L_3$is not context-free but recursive.
IV. L_4 is deterministic context-free.

(A) I, II and IV only (B) II and III only
(C) I and IV only (D) III and IV only

19. Consider the following languages:

I. $\{a^m b^n c^p d^q \mid m + p = n + q$, where $m, n, p, q \geq 0\}$
II. $\{a^m b^n c^p d^q \mid m = n$ and $p = q$, where $m, n, p, q \geq 0\}$
III. $\{a^m b^n c^p d^q \mid m = n = p$ and $p \neq q$, where $m, n, p, q \geq 0\}$
IV. $\{a^m b^n c^p d^q \mid mn = p + q$, where $m, n, p, q \geq 0\}$

Which of the languages above are context-free? **[2018]**

(A) I and IV only (B) I and II only
(C) II and III only (D) II and IV only

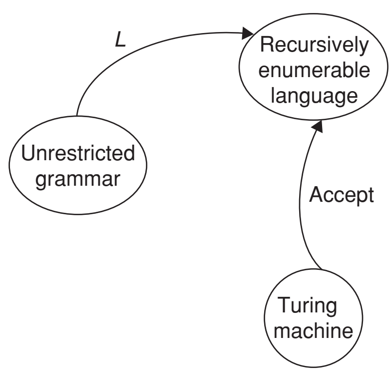
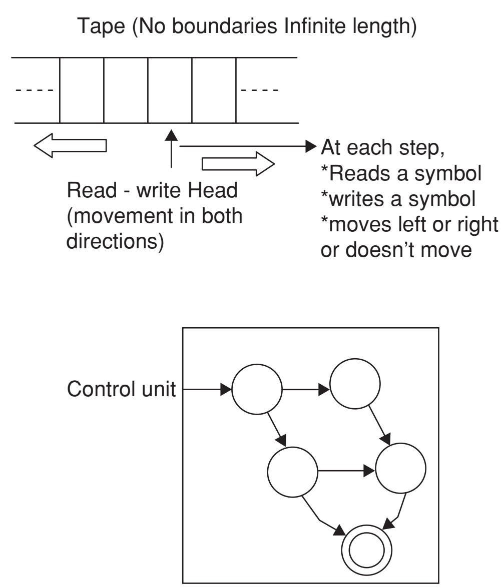
- *Church's hypothesis*
- *Halting problem*
- *Post's correspondence problem*
- *7 P problems*
- *NP problems*
- *NP – complete problem*
- *NP – hard problem*
- *Closure properties of formal languages*

Turing Machines



A Turing machine is a kind of state machine, which is much more powerful in terms of languages it can recognize. At any time, the machine is in any one of the finite number of states. Instructions for a turing machine include the specification of conditions, under which the machine will make transitions from one state to other.

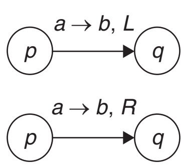
Model of Turing Machine



- A TM (turing machine) consists of Tape, Head, control unit.
- **Tape:** A tape is divided into a sequence of numbered cells, Each cell contains a symbol and cells that have not been written before are assumed to be filled with a blank symbol (B). The set of symbols of tape is denoted by Γ. The tape is assumed to be arbitrarily extensible to the left as well as to the right.
- **Head:** In a single step, a tape head reads the contents of a cell on the tape (reads a symbol), replaces it with some other characters (writes a symbol) and repositions itself to the next cell to the right or to the left of the one it has just read or does not move (moves left or right or does not move).
- **Control unit:** The reading from the tape or writing into the tape is determined by the control unit. It contains a finite set of states, Q. The states are:
  1. Initial state, q_0
  2. Halt state, h: This is state in which TM stops all further operations. There can be one or more halt states in a TM.
  3. Other states.

Note: A TM on entering the halt state stops making moves and whatever string is there on the tape, will be taken as the output, irrespective of whether the position of head is at the end or in the middle of the string on the tape.

Transition Diagram of TM



Reads a symbol
writes a symbol
Move Right (R)
Move Left (L)
No Move (N)

Specification of TM

5-Tuple specification:
TM = (state1, Read symbol, write symbol, $L/R/N$, state 2).
7 - Tuple specification of TM:
A TM, M is represented as a 7-tuple:
$M = (Q, \Sigma, \Gamma, \delta, q_0, B, h)$ where
$Q \rightarrow$ Finite set of states
$\Sigma \rightarrow$ Finite set of non-blank symbols
$\Gamma \rightarrow$ Set of tape characters
$q_o \rightarrow q_o \in Q$, initial state
$B \rightarrow$ Blank character
$h \rightarrow h \subseteq Q$, final state
$\delta \rightarrow$ Transition function, $Q \times \Gamma \rightarrow Q \times \Gamma\ x\ \{L, R, N\}$

String classes in TM

Every TM, over the alphabet Σ, divides set of input string w into three classes:

1. **Accept (TM):** It is the set of all strings $w \in \Sigma^* \ni$ if the tape initially contains w and the TM is then run, then TM ends in a halt state.
2. **LOOP (TM):** It is the set of all strings, $w \in \Sigma^* \ni$ if the tape initially contains w and the TM is then run, then the TM loops forever (infinite loop).
3. **Reject (TM):** It is the set of all strings $w \in \Sigma^* \ni$, any of the following 3-cases arise.

Case I: There may be a state and a symbol under the tape head, for which δ does not have a value.

Case II: If the head is reading the left most cell (i) containing the symbol x, the state of TM is say q, then δ (q, x) suggests a move to the left of the current cell. However as there is no cell to the left, no move is possible.

Case III: If TM enters an infinite loop or if a TM rejects a given string w, because of above two cases, TM crashes (terminates unsuccessfully).

Languages Accepted by a TM

- The language accepted by TM is the set of accepted strings $w \in \Sigma^*$.
- Formally, let $M = (Q, \Sigma, \Gamma, \delta, q_0, B, h)$ be a TM. The language accepted by M denoted by $L(M)$ is defined as, $L(M)$ = $\{w/w \in z^*$ and if $w = a_1 \ldots a_n$ then, $(q_o, \varepsilon, a_1, a_2, \ldots a_n)$ $(h, b, \ldots, b_{i-1}, b_j\, b_n)$ for some $b_1, b_2 \ldots b_n \in N^* \ni\}$

  $L(M) = \{W: q_o\ w \vdash^* x_1 h x_2\}$
- There are three types of turing machine related languages:
  1. **Turing Acceptable language:** A language, L over some alphabet is said to be turing acceptable language if there exists a TM, $M \ni L = L(M)$
  2. **Turing Decidable Language:** A language L over Σ i.e., $L \subseteq \Sigma^*$ is said to be turing decidable, if both languages, L and its complement $\Sigma^* - L$ are turing acceptable.
  3. **Recursively Enumerable Language:** A language L is recursively enumerable, if it is accepted by a TM.

Example 1: Let M be a turing machine has $M = (Q, \Gamma, \Sigma, \delta, S, B, F)$ with $Q = \{q_o, q_1, q_2, q_3, q_4\}$, $\Gamma = \{a, b, X, Y, \#\}$, $\Sigma = \{a, b\}$, $S = q_0$, $B = \#$, δ given by:

	a	b	X	Y	#
q_0	(q_1, X, R)	–	–	(q_3, Y, R)	
q_1	(q_1, a, R)	(q_2, Y, L)	–	(q_1, Y, R)	
q_2	(q_2, a, L)	–	(q_0, X, R)	(q_2, Y, L)	
q_3	–	–	–	(q_3, Y, R)	$(q_4, \#, R)$
q_4	–	–	–	–	–

Which of following is true about M?
(A) M halts on L having 'baa' as substring
(B) M halts on L having 'bab' as substring
(C) M halts on $L = \{a^n b^n / n \geq 1\}$
(D) M halts on L not having 'bbaa' as substring.

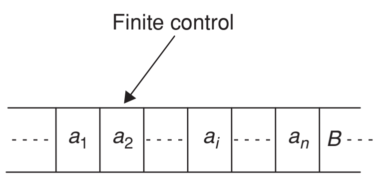
Solution: (C)
M accepts $a^n b^n$.

Example: *aaabbb*

$(q_0, \in, aaabbb)$	$\rightarrow$	$(q_1, XXXYY, b)$
$(q_1\ X, aabbb)$	$\rightarrow$	$(q_2\ XXXY, YY)$
$(q_1, Xa, abbb)$	$\rightarrow$	$^{1}(q_2, XXX, YYY)$
(q_1, Xaa, bbb)	$\rightarrow$	$(q_2, XY, XYYY)$
$(q_1, Xa, aYbb)$	$\rightarrow$	(q_0, XXX, YYY)
$(q_2, X, aaYbb)$	$\rightarrow$	$(q_3, XXXY, YY)$
$(q_2, \in, XaaYbb)$	$\rightarrow$	$(q_3, XXXYY, Y)$
$(q_o, X, aaYbb)$	$\rightarrow$	$(q_3, XXXYYY, \in)$
$(q_1, XX, aYbb)$	$\rightarrow$	$(q_4, XXXYYY\#, \in)$

Types of Turing Machines

Two-way infinite turing machine

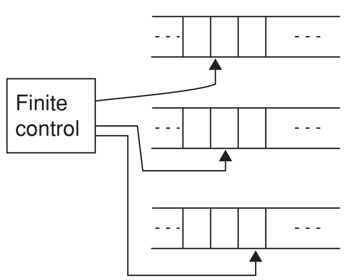


- A TM with a two-way infinite tape is denoted by $M = (Q, \Sigma, \Gamma, \delta, q_o, B, F)$, as in original model.
- The tape is infinite to the left as well as to the right.

If $\delta(q, x) = (p, Y, L)$ then $q\ x\ \alpha \vdash_m pBY$. The tape, is infinte towards left.

If $\delta\ (q, x) = (p, B, R)$ then $q\ x\ \alpha \vdash_m, p\alpha$ the is infinite towards right.

Multiple turing machines



- A multiple TM consists of a finite control with k tape heads and k-tapes, each tape is infinite in both directions, on a single move, depending on the state of the finite control and the symbol scanned by each of tape heads, the machine can,
  - change state
  - print new symbol on each of the cells scanned by its tape head
  - move each of its tape heads, independently, one cell to the left or right or keep it stationary.
- Initially, the input appears on the first tape and other tapes are blank.

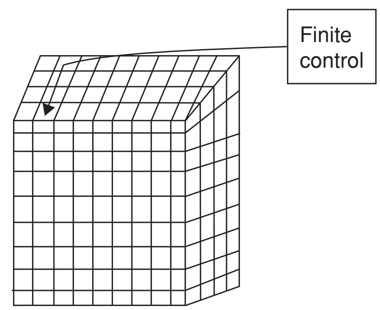
Non-deterministic turing machines

- A non-deterministic turing machine is a device with a finite control and a single one way infinite tape.
- For a given state and a tape symbol scanned by the tape head, the machine has a finite number of choices for next move.

Note: Non-deterministic TM is not permitted to make a move in which the next state is selected from one choice, and the symbol printed and direction of head motion are selected from other choices.

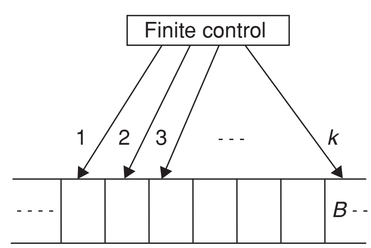
- The non-deterministic TM accepts its input if any sequence of choices of moves leads to an accepting state.

Multi-dimensional TM's



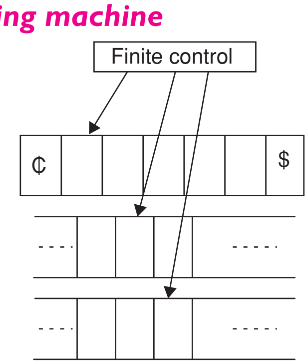
- The tape consists of a k-dimensional array of cells infinite in all 2k directions, for some fixed k.
- Depending on the state and the symbol scanned, the device changes it's state, prints a new symbol and moves its tape head in one of the $2k$ directions, either positively or negatively, along one of the k-axes.

Multihead TM



- A K-head TM has some fixed 'K' number of heads. The heads are numbered from 1 through k, and a move of the TM depends on the state and on the symbol scanned by each head.

Offline turing machine



- An offline TM is a multi tape TM, whose input tape is read only. The input is surrounded by end markers, ¢ on left and \$ on right. The TM is not allowed to move the input tape head off the region between ¢ and \$.

Multi stack machine

- A deterministic two stack machine is a deterministic TM with a read only input and two storage tapes.

Note:

- All these types of TM's does not add any language accepting power and all these are equivalent to the basic model.
- Any language accepted by a 2-PDA can be accepted by some TM and any language accepted by a TM can be accepted by some 2-PDA. Accepting power of a TM = accepting power of a computer.
- Any language accepted by a PDA with n stacks ($n \geq 2$), can also be accepted by some TM.

Example 2: Consider the following statement about L:

1. L is accepted by multi-tape turing machine M_1.
2. L is also accepted by single tape turing machine M_2.

Which of following statement is correct?

(A) Acceptance by M_2 is slower by $O(n^2)$
(B) Acceptance of M_2 is slower by $O(n)$
(C) Acceptance of M_2 is faster by $O(n)$
(D) Acceptance of M_2 is faster by $O(n^2)$

Solution: (A)
While simulating multi-tape TM on a single tape TM the head has to move at least $2k$ cells per move, where k is the number of tracks on single tape TM. Thus for k moves, $\sum_{i=1}^{k} 2i = 2k^2$.
Which means quadratic slow down?
Thus, acceptance of multi-tape is faster by $O(n^2)$.

Universal turing machine

A Universal turing machine is a turing machine that can simulate an arbitrary turing machine on arbitrary input.

- The machine consists of an input output relation to the machine computes.
- The input is given in binary form on the machine tape and the output consists of the contents of the tape when the machine halts.
- The contents of the tape will change based on the Finite State Machine (FSM) inside the TM.
- The problem with TM is that a different machine will be constructed for every new computation to be performed.
- A UTM can simulate any other machine.

Combining turing machines

If TM_1 and TM_2 are turing machines, then we can combine these machines and create a Turing machine which will first behave like TM_1 and TM_2.

To combine two turing machines follow below steps:

1. Change all states in TM_2, so that they do not conflict with the state names in TM_1.
2. Change all halts in TM_1's transition table to the new name of the start state of TM_2.
3. Append TM_2's transition table to the foot of TM_1's transition table.

- If TM_1 and TM_2 are combined in this way, we will write it as $TM_1 \rightarrow TM_2$.

So this new machine starts off in the initial state of TM_1, operates as per TM_1 until TM_1 would halt then it launches TM_2 and operates a TM_2, until TM_2 would halt.

Recursively Enumerable languages

- A language L over the alphabet Σ is called 'recursively enumerable' if there is a TM, M that accept every word in L and either rejects or loops for every word in language L', the complement of L.
  Accept $(M) = L$
  Reject (M) + Loop $(M) = L'$.
- When TM, M is still running on some input of recursively enumerable languages, it is not decided that M will eventually accept, if let it run for long time or M will run forever (in loop).

Recursive language

- A language is said to be recursive, if there exists a TM which will halt and accept when presented with any input string $w \in \Sigma^*$, only if the string is in the language otherwise will halt and reject the string.
- Thus, for turing decidable language L, there is a TM which halts for a large number of inputs w belonging to L.
- A TM that always halts is known as a decider or a total turing machine and is said to decide the recursive language. The recursive language is also called as recursive set of decidable.
- A language accepted by a TM is said to be recursively enumerable language. The subclass of recursively enumerable sets are said to be recursive sets or recursive language.

Note:

- All recursive languages are also recursively enumerable.
- There may be languages which are recursively enumerable but not recursive.
- Set of all possible words over the alphabet of the recursive language is a recursive set.

- Set of all possible words, over the alphabet of the recursive enumerable language, is a recursively enumerable set.

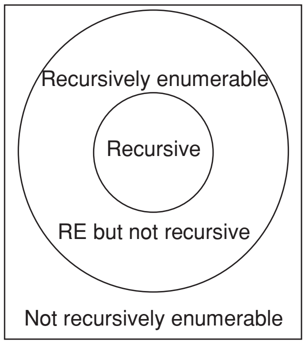


Figure 1 Relationship between the recursive, RE and non-RE languages.

Properties of Recursive and Recursively Enumerable Languages

- If a language L is recursive, then there is a TM T that accepts it and always halts.
- If L and L_I are both recursively enumerable, then L and L_I are recursive.
- Union of two recursive languages is recursive.
- Recursively enumerable languages are closed under union.
- If L, L_1 and L_2 are recursive languages, then so are $L_1 \cup L_2$, $L \cap L_2$, L_1L_2, L^*, $L_1 \cap L_2$ and $L_1 - L_2$.
- If L, L_1 and L_2 are recursively enumerable languages, then so are $L_1 \cup L_2$, L^*, $L_1 \cap L_2$, L_1L_2.
- If Σ is an alphabet, $L \subseteq \Sigma^*$, is a recursively enumerable language and $\Sigma^* - L$ is recursively enumerable, then L is recursive.

Example 3: If $\Sigma = \{0,1\}$, the canonical order is $\{\in,0,1,00,01,10,11,000,\ldots\}$ where w is the i^{th} word and M_j is TM whose code is the integer j, written in binary. The language generated is $L(M_j)$. The diagonalized language, L_d is a.

(A) Recursively enumerable language but not recursive
(B) Recursive language
(C) Non-recursively enumerable language
(D) Both (a) and (c)

Solution: (C)
Non-recursively enumerable language.

Non-recursively enumerable language

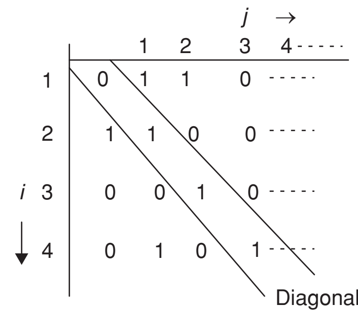
Non-Recursively Enumerable Language: A language which is not accepted by any turing machine is non-recursively enumerable.

Example: Power set of an infinite set.

- These languages cannot be defined by any effective procedure.

For any non-empty Σ, there exist languages that are not Recursively Enumerable.

Infinite table for all i and j is:



To guarantee that no TM accepts L_d:

w_i is in L_d if and only if the (i, i) entry is 0, that is, if M_i does not accept w_i.

Suppose that some TM M_j accepted L_d. Then it contradicts if w_j is in L_d, (j, j) entry is 0, implying that w_j is not in $L\,(M_j)$ and contradicting $L_d = L\,(M_j)$.

If w_i is not in L_d, then the (j, j) entry is 1, implying that w_i is in $L(M_j)$, which again contradicts $L_d = L(M_j)$, as w_j is either in or not in L_d, assumption, $L_d = L(M_j)$ is false.

Thus no TM in the list accepts L_d, Hence L_d is non-recursively enumerable language.

Decidable: A problem with two answers (Yes/No) is decidable if the corresponding language is recursive.

Example:

1. $A_{DFA} = \{(M, w)\ M$ accepts the input string $w\}$.

- A Language L is turing decidable, if there exists a TM M such that on input x, M accepts if $x \in L$ and M rejects otherwise. L is called undecidable if it is not decidable.
- Decidable Languages correspond to algorithmically solvable Decision problems.
- Undecidable language corresponds to algorithmically unsolvable decision problems.

Closure properties of decidable languages

- Decidable Languages are closed under complement, union, intersection, concatenation and star (closure) operations.

Note 1: A language is decidable if both the language and its complement are recognizable.

Note 2: Turing Decidable languages are Recursive languages.

Undecidability

There are problems that can be computed. There are also problems that cannot be computed. These problems which cannot be computed are called 'computationally undecidable problems'.

Church's Hypothesis

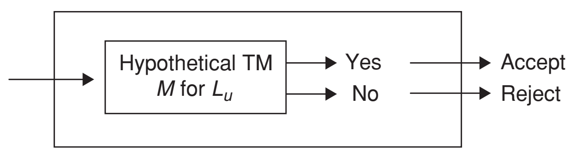
There is an assumption that the intuitive notion of computable functions can be identified with partial recursive functions.

However, this hypothesis cannot be proved. The computability of recursive function is based on following assumptions:

1. Each elementary function is computable.
2. Let 'f' be a computable function and 'g' be another function which can be obtained by applying an elementary operation to f, then g becomes a computable function.
3. Any function becomes computable, if it is obtained by rule (1) and (2).

Undecidability of the universal languages

- The universal language, L_u is a recursively enumerable language but not recursive.



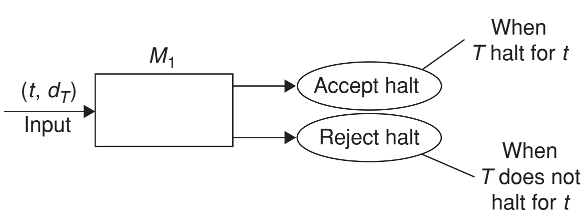
Halting Problem

The given configuration of TM is required to state halting problem. The output of TM can be:

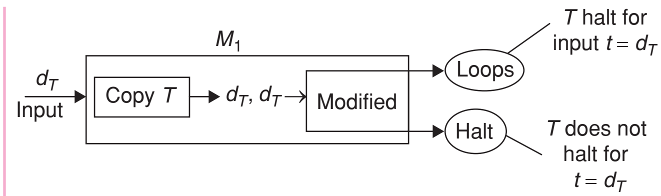
1. **Halt:** The machine starting at this configuration will halt after a finite number of states.
2. **No Halt:** The machine starting at this configuration never reaches a halt state, no matter how long it runs.

- The halting problem is unsolvable because, let, there exists a TM, M, which decides whether or not any computation by a TM, T will ever halt when a description d_T of T and tape t of T is given. That means the input to machine M, will be (machine, tape) pair. Then for every input (t, dT) to M_I if T halt for input t, M_I also halts which is called accept halt.

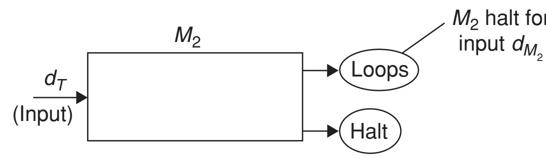
Similarly if T does not halt for input t then the M_1 will halt which is called reject halt.



- Consider another Turing Machine, M_2 which takes an input d_T. It first copies d_T on its tape and then this duplicated tape information is given as input to M_1. But M_1 is a modified machine.



Replace T by M_2 i.e., $M_2 = T$



That's means, a machine M_1, which can tell whether any other TM will halt on particular input does not exist. Hence halting problem is unsolvable.

Post's Correspondence Problem (PCP)

The Undecidability of strings is determined with the help of Post's Correspondence Problem (PCP).

'The PCP consists of two lists of strings that are of equal length over the input Σ. The two lists are $A = w_1, w_2, w_3, \ldots w_n$ and $B = x_1, x_2, \ldots x_n$ then there exists a non-empty set of integers $i_1, i_2, \ldots i_n$ such that $w_1, w_2, \ldots w_n = x_1, x_2, \ldots x_n$'.

To solve PCP, try all the combinations of $i_1, i_2, \ldots i_n$ to find the $w_i = x_i$ then, PCP has a solution.

Example 4: What is the solution for the following system of post correspondence problem. $A = \{100, 0, 1\}$ $B = \{1, 100, 00\}$

(A) 1113322 (B) 1311322
(C) 2233111 (D) No solution

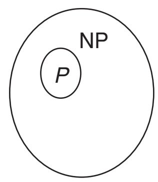
Solution: (B)
The string is:
A1A3A1A1A3A2A2 = 100 + 1 + 100 + 100 + 1 + 0 + 0 = 1001100100100,
B1B3B1B1B3B2B2 = 1 + 00 + 1 + 1 + 00 + 100 + 100 = 1001100100100.

Problems

- P stands for deterministic polynomial time. A deterministic machine at each time executes an instruction. Depending on instruction, it then goes to next state which is unique. Hence, time complexity of deterministic TM is the maximum number of moves made by M in processing an input string of length n, taken over all inputs of length n.
- A language, L is said to be in class P, if $\exists$ a (deterministic) TM, M is of time complexity $P(n)$ for some polynomial P and M accepts L.
- Class P consists of those problems that are solvable in polynomial time by a deterministic TM.

NP Problems

- NP stands for non-deterministic polynomial time.
- A language, L is in class NP, if there is a non-deterministic TM, M is of time complexity $P(n)$ for some polynomial P and M accepts L.
- Class NP consists of problems for which solutions are verified quickly. P consist of problems which can be solved quickly.



- NP languages are closed under union, Intersection, concatenation, Kleen star.
- NP problems are classified into two types:
  1. NP-complete
  2. NP-hard problems.

Example: Vertex (Graph) coloring problem, Travelling salesman problem, the vertex cover problem, the Hamiltonian circuit problem.

NP-Complete Problem

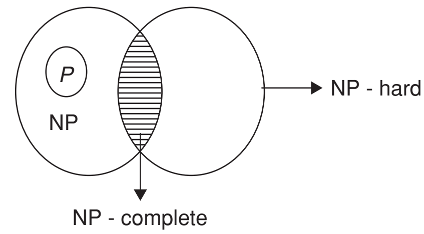
- A class of problems are known as NP-complete problems whose status is unknown. No polynomial time has yet been discovered for NP-complete problems nor has any one been able to prove that no polynomial time exists for any of them. These are hardest of NP-problems. The P and NP-complete problems are disjoint.

Example: (Cook's Theorem) SAT is NP-complete, Bin packing problem, Knapsack Problem.

- A language L is said to be NP-complete if $L \in NP$ and if every $L^I \in$ NP is polynomial-time reducible to L.

A language L_1 is said to be polynomial time reducible to some language L_2 if there exists a DTM by which any w_1 in the alphabet of L_1 can be transformed in polynomial time to a w_2 in the alphabet of L_2 in such a way that $w_1 \in L_1$ if $w_2 \in L_2$. It follows that if some L_1 is NP-complete and polynomial time reducible to L_2, then L_2 is also NP-complete.

NP-Hard Problem



- A problem that is NP-hard has a property that all problems that are in NP can be reduced in polynomial time to it.
- A language, L in NP-hard complete if and only if,

Condition 1: For every language, L^I in NP, there is a polynomial time reduction of L^I to L.

Condition 2: L is not necessarily in NP.

Table 1 *NP-Hard versus NP-complete problems:*

NP-Hard	NP-Complete
(1) A decision problem P_i is NP-hard if every problem in NP is polynomial time reducible to P_i.	(1) A Decision problem P_i is NP-complete if it is NP-hard and is also in class NP itself.
(2) In terms of symbols 'P_i' is NP-hard if for every $P_j \to$ NP	(2) In terms of symbols, 'P_i' is NP-complete, if P_i is NP-hard and $P_j \to$ NP
(3) P_i is 'as hard as' all the problem in NP	(3) P_i is one of the hardest problems in NP
(4) If any problem in NP is proved intractable, then P_i must also be intractable	(4) If any one ever shows that as NP-complete problem is also intractable, then every NP-complete problem is also intractable.

Example 5: Which of following is FALSE?

(A) $\{< x, y > \mid x$ and y are integers, gcd $(x, y) = 1\}$ is a NP class problem.
(B) CLIQUE is a NP class problem.
(C) Eulerian PATH is a P class problem
(D) Dijkstra's algorithm is a problem in P.

Solution: (A)
Choice (A) is a P class problem.
Consider the following table:

D – Decidable, U – Undecidable,? – Open question,T – Trivially Decidable Question	Regular Sets	DCFL's	CFL's	CSL's	Recursive Sets	Recursively Enumerable Sets

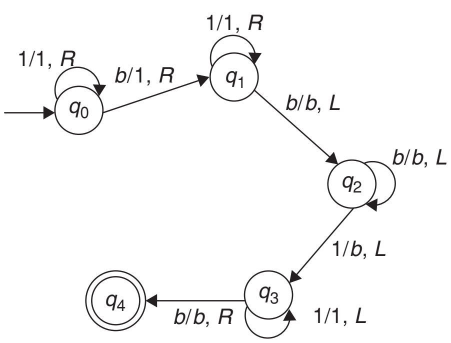
Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. The TM M over $\Sigma = \{1\}$ is given below



What does M generate?
(A) The output is total recursive multiplication function.
(B) The output is addition of two integers.
(C) The output is subtraction of two integers.
(D) The output should be w_1w_2 if input = (w_1w_2) a pair of words.

2. Consider language,

A = {<M>: M is a DFA which doesn't accept any string containing odd number 1's}

Which of following is true about A?
(A) A is Trivially decidable (B) A is undecidable
(C) A is decidable (D) None of these

3. Consider EQ_{CFG} = {<G_1G_2>: G_1, G_2 are CFGs and $L(G_1) = L(G_2)$}. Which of following is true about EQ_{CFG}?
(A) Recognizable (B) Co-Recognizable
(C) Un-recognizable (D) None of the above.

4. A language is given as INFINITE_{DFA} = {<A>: A is a DFA and $L(A)$ is an infinite language}. Which of following is true?
(A) Un-decidable (B) Decidable
(C) Trivially decidable (D) None of above.

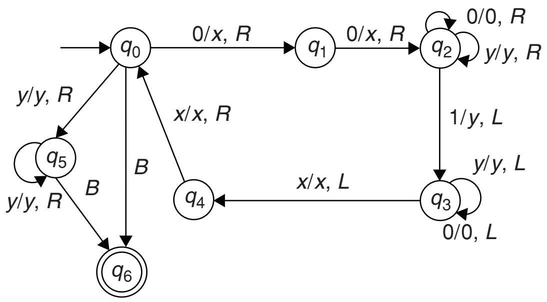
5. A TM designed over an alphabet {0, 1, #}, where 0 indicates blank, which takes a non-null string of 1's and #'s and transfer's the right-most symbol to the left-most end contains-states. (Ex: 000#1#1#1000 … becomes 0001#1#1#000)
(A) 4 (B) 3
(C) 6 (D) 5.

6. Which of following statements are true?
(i) Let K, L be decidable languages. The concatenation of languages, K, L is also decidable language.
(ii) Let L be Turing recognizable language. Then the complement, L^1 is also Turing recognizable language.
(A) (i) and (ii) (B) Only (ii)
(C) Both are false (D) Only (i)

7. Let T_i: denote i th TM. Given, X determines whether $X \in S$, Where the set S is defined inductively as follows: If $u \in S$, then $u^2 + 1$, $3u + 2$ and $u!$ are all members of S. Which of following is true about the given decision problem?
(A) Decidable (B) Un-decidable
(C) Trivially decidable (D) No solution.

8. Fermat's last theorem asserts that there are no integer solution (x, y, z, n) to equation $x^n + y^n = z^n$ satisfying $x, y > 0$ and $n > 2$. Which of the following is true regarding the halting problem?
(A) Decidable
(C) Un-decidable
(C) Trivially decidable
(D) May or may not have solution.

9. The TM, T is designed as



Which of following is true?

(A) T halts on 0^n1^n, $n \geq 0$

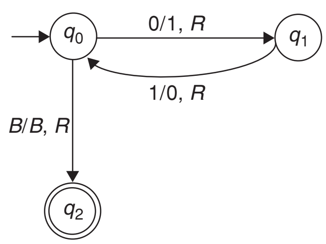
(B) T halts on (01) $(0^n 1^n)$, $n \geq 0$

(C) T halts on $0^{n^2}1^{n^2}$, $n \geq 0$

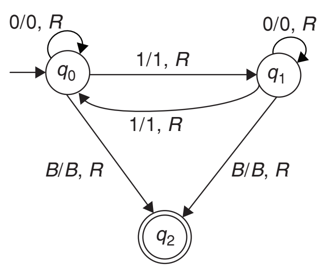
(D) T halts on $0^{2n}1^n$, $n \geq 0$

10. Design TM, which reads an input and starts inverting 0's to 1's till the first 1. The first 1 also inverted. After it has inverted first 1, it read the next symbols and keeps them as they are till the next 1. After encountering 1, it starts repeating the cycle by inverting the symbol till next 1. It halts when it encounters a blank symbol?

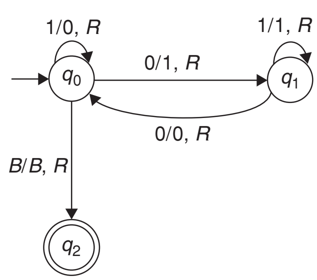
(A)



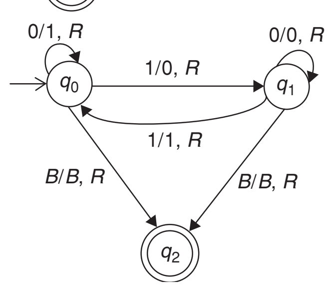
(B)



(C)



(D)



11. Consider three problems, P_1, P_2 and P_3. It is known that P_1 has polynomial time solution, P_2 is NP-complete and P_3 is in NP. Which one of the following is true?

(A) P_3 has polynomial time solution if P_1 is polynomial time reducible to P_3.

(B) P_3 is NP-complete if P_3 is polynomial time reducible to P_2.

(C) P_3 is NP complete if P_2 is reducible to P_3

(D) P_3 has polynomial time complexity and P_3 is reducible to P_2.

12. Let FHAM be the problem of finding a Hamiltonian cycle in a graph G and DHAM be the problem of determining if a Hamiltonian cycle exists in a graph. Which one of the following is true?

(A) Both FHAM and DHAM are NP-hard.

(B) FHAM is NP-hard, but DHAM is not.

(C) DHAM is NP-hard but FHAM is not.

(D) Neither DHAM nor FHAM is NP-hard.

13. The solution for the system of post correspondence problem, $A = \{ba, abb, bab\}$, $B = \{bab, bb, abb\}$ is

(A) 1312212 (B) 15234434

(C) 1311322 (D) No solution.

14. A language, prefix_free REX = $\{R/R$ is a regular expression where $L(R)$ is prefix_free$\}$. Which of following is true about prefix _free REX?

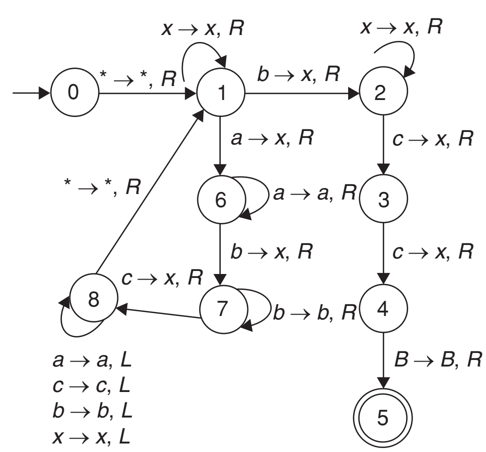
(A) Decidable

(B) Un-decidable

(C) Trivially decidable.

(D) Can't be determined.

15. The TM, M is designed as:



Which of following is true about M?

(A) M is designed for $a^n b^n c^n$, $n \geq 0$

(B) M is designed for $a^{n^2} b^{n^3} c^{n^4}$, $n \geq 0$

(C) M is designed for $a^n b^{n+1} c^{n+2}$, $n \geq 0$

(D) M is designed for $a^n b^n c^n$, $n > 0$

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Consider the language, $A\varepsilon_{\_CFG} = \{<G>: G$ is a CFG that generates$\varepsilon\}$. Which of the following is true?
(A) Undecidable
(B) Decidable
(C) Trivially decidable.
(D) None of the above.

2. The TM is designed with input and output as binary form. (# represents blank). The turing machine TM (M) is

	0	1	#
$q0$	($q1$, 0, R)	(q, 1, R)	ϕ
$q1$	($q1$, 0, R)	(q, 1, R)	($q2$, #, L)
$q2$	($q3$, #, L)	($q3$, #, L)	ϕ
$q3$	($q3$, 0, L)	($q3$, 1, L)	($q4$, #, L)
$q4$	ϕ	ϕ	ϕ

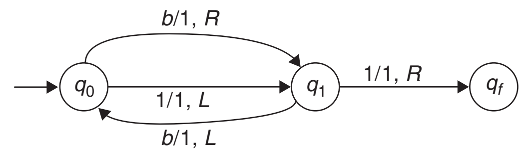
Which of following is true?
(A) M accepts $2n$
(B) M accepts n^2
(C) M replaces left most symbol with #
(D) M replaces right most symbol with #

3. The TM is designed with 3-characters 0, 1, # to compute function $f(n) = 2n$. Input and output are to be in binary form and string represented by 'n' is enclosed between two #'s on left and right of it. b is blank symbol. TM contains _____ states.
(A) 4 (B) 3
(C) 2 (D) 1

4. The language $\{1^n | n$ is a prime number$\}$ is
(A) Undecidable
(B) Decidable
(C) Trivially decidable
(D) None of the above

5. Which of following statement(s) are true?
(i) Let L be Turing decidable language. Then the complement $\bar{L}$ is also Turing decidable language.
(ii) Let K and L be two Turing recognizable languages. The intersection, $K \cap L$ is also Turing recognizable language.
(A) Both (i) and (ii)
(B) Only (i)
(C) Only (ii)
(D) Neither (i) nor (ii) are true.

6. For the following two-way infinite TM, the equivalent one-way TM contains _____ states.



(A) 7 (B) 6
(C) 5 (D) 4

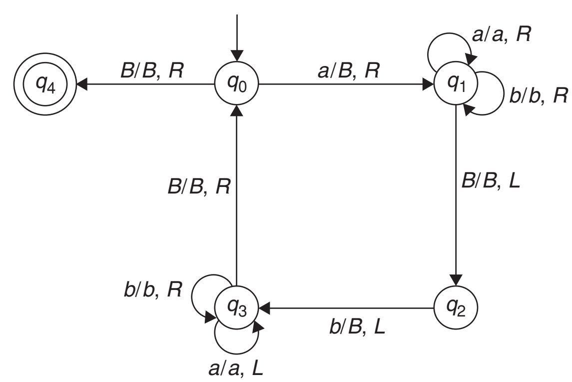
7. L contains at least two strings. Which of following is true?
(A) L has recursively enumerable sets and recursive.
(B) L is recursive.
(C) L has recursively enumerable sets but not recursive.
(D) L does not contain recursively enumerable sets and also is not recursive.

8. Consider the following TM:

Input / State	0	1	B
→ q_0	($q0$, 1, R)	($q0$, 0, R)	($q1$, B, R)
$q1$	–	–	–

What does TM generates?
(A) It display's the negative of given binary number.
(B) It computes one's complement of a binary number.
(C) It computes two's complement of a binary number
(D) It generates double the 0's as 1's.

9. Consider the following TM, M:



Which of following is true?
(A) M halts on $a^{n+1}\, b^n$, $n \geq 0$.
(B) M halts on a^{n^2}, b^{n^3} $n \geq 0$.
(C) M halts on $(ab)\,(a^n)$, $n \geq 0$.
(D) M halts on $a^n\, b^n$, $n \geq 0$.

10. A TM, M is designed generates language $L = \{a^n b^m : n \geq 1$ and $n \neq m\}$. The number of states used are ________
(A) 5 (B) 6
(C) 7 (D) 4

11. Consider three decision problems p_1, p_2 and p_3. It is known that p_1 is decidable, p_2 is undecidable. Which one of following is true?
(A) p_3 is decidable if p_1 is reducible to p_3
(B) p_3 is undecidable if p_3 is reducible to p_2
(C) p_3 is undecidable if p_2 is reducible to p_3
(D) p_3 is decidable if p_3 is reducible to p_2's complement.

12. Which one of following is not decidable?
(A) Given a TM, M, a string S, and an integer K, M accepts S with in K-steps.
(B) Equivalence of two given Turing machines.
(C) Language accepted by a given DFSA is non-empty.
(D) Language accepted by a CFG is non-empty.

13. What is the solution for the correspondence system with two lists $x = \{b, bab^3, ba\}$ and $y = \{b^3, ba, a\}$
(A) 1312213 (B) 2113
(C) 3112 (D) No solution.

14. Given a Turing machine M, a state 'q'and a string 'w'. To determine whether M ever reaches state q when started with input w from its initial state is?
(A) Decidable
(B) Un-decidable
(C) Trivially decidable.
(D) Can not be determined.

15. Given a Turing machine, M to determine whether M ever moves its head to the left when started with input W is:
(A) Decidable
(B) Un-decidable
(C) Trivially decidable.
(D) Can not be determined.

Previous Years' Questions

1. For $s \in (0 + 1)^*$, let $d(s)$ denote the decimal value of s (e.g., $d(101) = 5$). **[2006]**

Let $L = \{s \in (0+1)^* | d(s) \bmod 5 = 2 \text{ and } d(s) \bmod 7 \neq 4\}$

Which one of the following statements is true?
(A) L is recursively enumerable, but not recursive
(B) L is recursive, but not context-free
(C) L is context-free, but not regular
(D) L is regular

2. Which of the following is true for the language $\{a^p \mid p$ is a prime$\}$? **[2008]**
(A) It is not accepted by a Turing Machine
(B) It is regular but not context-free
(C) It is context-free but not regular
(D) It is neither regular nor context-free, but accepted by a Turing machine

3. If L and $\overline{L}$ are recursively enumerable then L is **[2008]**
(A) regular
(B) context-free
(C) context-sensitive
(D) recursive

4. Let $L = L_1 \cap L_2$, where L_1 and L_2 are languages as defined below:

$L_1 = \{a^m b^m c a^n b^n \mid m, n \geq 0\}$

$L_2 = \{a^i b^j c^k \mid i, j, k \geq 0\}$

Then L is **[2009]**
(A) Not recursive
(B) Regular
(C) Context free but not regular
(D) Recursively enumerable but not context free.

5. Let L_1 be a recursive language. Let L_2 and L_3 be languages that are recursively enumerable but not recursive. Which of the following statements is not necessarily true? **[2010]**
(A) $L_2 - L_1$ is recursively enumerable
(B) $L_1 - L_3$ is recursively enumerable
(C) $L_2 \cap L_1$ is recursively enumerable
(D) $L_2 \cup L_1$ is recursively enumerable

6. Which of the following statements is/are FALSE? **[2013]**
1. For every non-deterministic Turing machine, there exists an equivalent deterministic Turing machine.
2. Turing recognizable languages are closed under union and complementation.
3. Turing decidable languages are closed under intersection and complementation.
4. Turing recognizable languages are closed under union and intersection.

(A) 1 and 4 only (B) 1 and 3 only
(C) 2 only (D) 3 only

7. Let L be a language and $\overline{L}$ be its complement. Which one of the following is NOT a viable possibility? **[2014]**
(A) Neither L nor $\overline{L}$ is recursively enumerable ($r. e$)
(B) One of L and $\overline{L}$ is r.e. but not recursive, the other is not r. e.
(C) Both L and $\overline{L}$ are r.e. but not recursive
(D) Both L and $\overline{L}$ are recursive

8. Let $A \leq_m B$ denotes that language A is mapping reducible (also known as many-to-one reducible) to language B. Which one of the following is FALSE? **[2014]**
(A) If $A \leq_m B$ and B is recursive then A is recursive.
(B) If $A \leq_m B$ and A is undecidable then B is undecidable.
(C) If $A \leq_m B$ and B is recursively enumerable then A is recursively enumerable.

(D) If $A \leq_m B$ and B is not recursively enumerable then A is not recursively enumerable.

9. Let <*M*> be the encoding of a Turing machine as a string over $\Sigma = \{0, 1\}$. Let L = {<*M*>|*M* is a *Turing machine that accepts a string of length* 2014}. Then, L is
(A) Decidable and recursively enumerable
(B) Undesirable but recursively enumerable
(C) Undesirable and not recursively enumerable
(D) Decidable but not recursively enumerable

10. For any two languages L_1 and L_2 such that L_1 is context-free and L_2 is recursively enumerable but not recursive, which of the following is/are necessarily true? **[2015]**
I. $\overline{L_1}$ (complement of L_1) is recursive
II. $\overline{L_2}$ (complement of L_2) is recursive
III. $\overline{L_1}$ is context-free
IV. $\overline{L_1} \cup L_2$ is recursively enumerable
(A) I only (B) III only
(C) III and IV only (D) I and IV only

11. Consider the following statements.
I. The complement of every Turning decidable language is Turing decidable.
II. There exists some language which is in NP but is not Turing decidable.
III. If L is a language in NP, L is Turing decidable.
Which of the above statements is/are true? **[2015]**
(A) Only II (B) Only III
(C) Only I and II (D) Only I and III

12. Let X be a recursive language and Y be a recursively enumerable but not recursive language. Let W and Z be two languages such that $\bar{y}$ reduces to W, and Z reduces to $\bar{x}$ (reduction means the standard many-one reduction). Which one of the following statements is **TRUE?** **[2016]**
(A) W can be recursively enumerable and Z is recursive.
(B) W can be recursive and Z is recursively enumerable.
(C) W is not recursively enumerable and Z is recursive.
(D) W is not recursively enumerable and Z is not recursive.

13. Consider the following types of languages: L_1: Regular, L_2: Context - free, L_3: Recursive, L_4: Recursively enumerable. Which of the following is / are TRUE? **[2016]**
I. $\overline{L_3} \cup L_4$ is recursively enumerable
II. $\overline{L_2} \cup L_3$ is recursive
III. $L^*_1 \cap L_2$ is context - free
IV. $L_1 \cup \overline{L_2}$ is context - free
(A) I only (B) I and III only
(C) I and IV only (D) I, II and III only

14. Consider the following languages. **[2016]**
L_1= {<*M*> | *M* takes at least 2016 steps on some input},
L_2= {<*M*> | *M* takes at least 2016 steps on all inputs} and
L_1= {<*M*> | *M* accepts ε}
where for each Turing machine *M*, <*M*> denotes a specific encoding of M. Which one of the following is TRUE?
(A) L_1 is recursive and L_2, L_3 are not recursive
(B) L_2 is recursive and L_1, L_3 are not recursive
(C) L_1, L_2 are recursive L_3 is not recursive
(D) L_1, L_2, L_3 are recursive

15. Let A and B be finite alphabets and let # be a symbol outside both A and B. Let f be a total function from A^* to B^*. We say f is *computable* if there exists a turning machine M which given an input x in A^*, always halts with $f(x)$ on its tape. Let L_f denote the language $\{x \# f(x) | x \in A^*\}$. Which of the following statements is true: **[2017]**
(A) f is computable if and only if L_f is recursive.
(B) f is computable if and only if L_f is recursively enumerable.
(C) If f is computable then L_f is recursive, but not conversely.
(D) If f is computable then L_f is recursively enumerable, but not conversely.

16. Let $L(R)$ be the language represented by regular expression R. Let $L(G)$ be the language generated by a context free grammar G. Let $L(M)$ be the language accepted by a Turing machine M. Which of the following decision problems are undecidable? **[2017]**
I. Given a regular expression R and a string w, is $w \in L(R)$?
II. Given a context-free grammar G, is $L(G) = \emptyset$?
III. Given a context-free grammar G, is $L(G) = \Sigma^*$ for some alphabet Σ ?
IV. Given a Turing machine M and a string w, is $w \in L(M)$?
(A) I and IV only (B) II and III only
(C) II, III and IV only (D) III and IV only

17. The set of all recursively enumerable languages is: **[2018]**
(A) Closed under complementation.
(B) Closed under intersection.
(C) A subset of the set of all recursive languages.
(D) An uncountable set.

18. Consider the following problems. $L(G)$ denotes the language generated by a grammar G. $L(M)$ denotes the language accepted by a machine M.

(I) For an unrestricted grammar G and a string w, whether $w \in L(G)$

(II) Given a Turing machine M, whether $L(M)$ is regular

(III) Given two grammars G_1 and G_2, whether $L(G_1) = L(G_2)$

(IV) Given and NFA N, whether there is a deterministic PDA P such that N and P accept the same language.

Which one of the following statements is correct? **[2018]**

(A) Only I and II are undecidable
(B) Only III is undecidable
(C) Only II and IV are undecidable
(D) Only I, II and III are undecidable

Test

Theory of Computation

Time: 60 min.

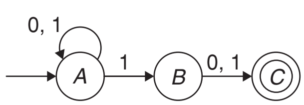
Directions for questions 1 to 30: Select the correct alternative from the given choices.

1. Phrase structure languages, context-sensitive languages, context-free languages and regular languages are commonly referred to as languages of type-0, 1, 2, and 3 respectively. Then, Chomsky's Hierarchy states that
(A) type-0 $\supseteq$ type-1 $\supseteq$ type-2 $\supseteq$ type-3
(B) type-0 $\supset$ type-1 $\supset$ type-2 $\supset$ type-3
(C) type-0 $\subset$ type-1 $\subset$ type-2 $\subset$ type-3
(D) type-0 $\subseteq$ type-1 $\subseteq$ type-2 $\subseteq$ type-3

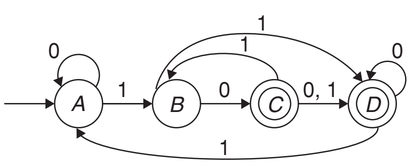
2. Let L be a language recognizable by a finite automaton. The language Reverse $(L) = \{x$ such that x is the reverse of y where $y \in L\}$ is a
(A) Regular language
(B) Context-sensitive language
(C) Context-free language
(D) Phrase-structure language

3. Which of the following statement is true?
(A) It is possible to construct an NFA with more number of states than its equivalent minimum DFA.
(B) There can be a DFA with more than one start state.
(C) Both (A) and (B)
(D) None of these

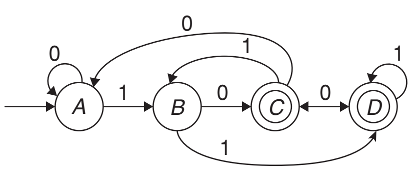
4. Which of the following is an equivalent DFA for the NFA shown below:



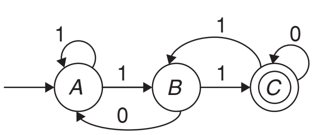
(A)



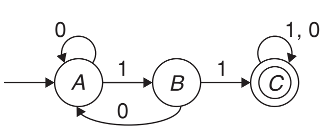
(B)



(C)

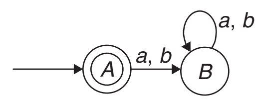


(D)



5. Which one of the following regular expressions over $\{0, 1\}$ denotes the set of strings not containing 100 as a substring?
(A) $0^*(1^*0)^*$ (B) $0^*1^*01^*$
(C) $(0^*(10 + 1)^*)^*$ (D) 0^*1010^*

6. The following transition diagram of a finite automaton accepts



(A) All word over sigma (a, b) such that symbol a and b alternate.
(B) Only empty string.
(C) Only the λ_1 meaning this automaton accepts no string of length greater than zero.
(D) All words over sigma (a, b) except λ.

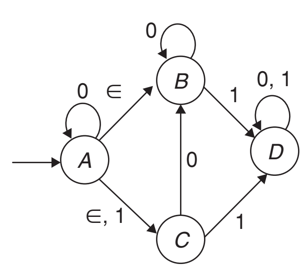
7. Sentence that can be generated from the following production grammar is
$S \rightarrow aS/bA$
$A \rightarrow d/ccA$
(A) *aabccccd* (B) *ababccccd*
(C) *bccddd* (D) *aaccdb*

8. Pumping lemma is generally used for proving
(A) A given grammar is regular
(B) A given grammar is non-regular
(C) Whether two given regular expression are equivalent or not
(D) Both (A) and (C)

9. Finite state machine can recognize
(A) Only context-free grammar
(B) Only regular grammar
(C) Any unambiguous grammar
(D) Any grammar

10. Which of the following is false?
(A) Regular sets are closed under reversal.
(B) Regular sets are closed under substitution.
(C) Regular sets are closed under intersection.
(D) None of these

11. For the DFA shown below $\hat{\delta}(A, 01)$ will be



(A) $\{B, D\}$ (B) $\{C, D\}$
(C) $\{A, B, C\}$ (D) $\{A, B, C, D\}$

12. 'NFA can be simulated by a DFA'. The statement is
(A) True (B) False
(C) Depends on NFA (D) Depends on DFA

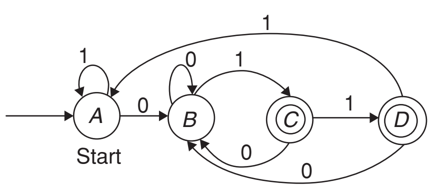
13. Given an arbitrary non-deterministic finite automaton (NFA) with N states, the maximum number of states in an equivalent minimized DFA is at least
(A) N^2 (B) 2^N
(C) $2N$ (D) $N!$

14. Let $M = (K, \Sigma, \delta, S, F)$ be a finite state automaton, Where
$K = \{A, B\}$
$\Sigma = \{a, b\}$
$S = A$
$F = \{B\}$,
$\delta(A, a) = A$
$\delta(A, b) = B$
$\delta(B, a) = B$ and
$\delta(B, b) = A$.

A grammar to generate the language accepted by M can be specified as $G = (V, \Sigma, R, S)$, where

$V = K \cup \Sigma$, and $S = A$. Which one of the following set of rules will make $L(G) = L(M)$?
(A) $\{A \to aB, A \to bA, B \to bA, B \to aA, B \to \in\}$
(B) $\{A \to aA, A \to bB, B \to aB, B \to bA, B \to \in\}$
(C) $\{A \to bB, A \to aB, B \to aA, B \to bA, B \to \in\}$
(D) $\{A \to aA, A \to bA, B \to aB, B \to bA, A \to \in\}$

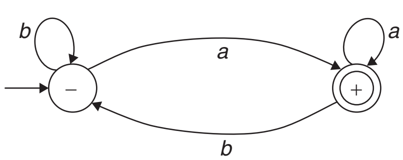
15 A deterministic finite automaton M shown below has a start state A and accepting state D. Which of the following regular expression denotes the set of all words accepted by M?



(A) 0 0 1 (B) 1 0* 1* 10
(C) 1* 0* 0 0 1 (D) (0/1)* 0 1 1

16. Which of the following regular expression is/are true?
(A) $(x^*)^* = x^*$ (B) $(x + y)^* = x^* + y^*$
(C) $x^*y^* = x^* + y^*$ (D) All of these

17. Consider the FA shown in the figure given below, where '–' is the start sate and '+' is the ending state. The language accepted by the FA is



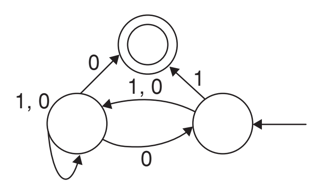
(A) $(a + b)^*b$ (B) $(a + b)^*a$
(C) a^*b (D) a^*b^*

18. Which of the following statement is false?
(A) The family of regular language is closed under the complementary operation.
(B) If L is a regular language, $L_1 = \{UV: U \in L, |V| = 2\}$ is also regular.
(C) If L is a regular language, $L_1 = \{UV: U \in L, V \in L^R\}$ is also regular.
(D) None of these

19. Which of the following is false?
(A) $L = \{0^i\, 1^m 2^m: i \geq 1, m \geq 1\}$ over $\Sigma = \{0, 1, 2\}$ is regular.
(B) $L = \{a^n\, b^l\, a^k, k \geq n + l\}$ is not regular.
(C) $L = \{UWW^2V: U, V, W \in \{a, b\}^+\}$ is regular.
(D) $L = \{a_n b_k : n > k\} \cup \{a_n b_k : n \neq k - 1\}$ is not regular.

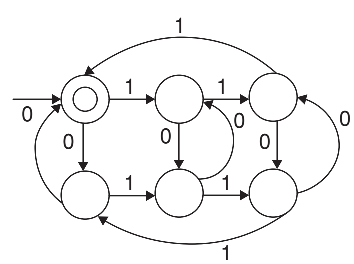
20. Consider a DFA over $\Sigma = \{a, b\}$ accepting all strings which have number of a's divisible by 6 and number of b's divisible by 8. What is the minimum number of states that the DFA will have?
(A) 16 (B) 15
(C) 48 (D) 8

21. For the NFA M given below. Let the language, accepted by M be L. Let L_1 be the language accepted by the NFA M_i, obtained by changing the accepting state of M to a non-accepting state and by changing the non-accepting states of M to accepting states. Which of the following statement is true?



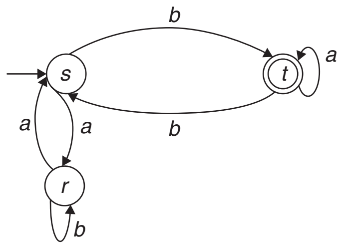
(A) $L_1 = A$ (B) $L_1 \subseteq L$
(C) $L_1 = \{0, 1\}^*$ (D) $L_1 = (0, 1\}^* - L$

22. The following finite state machine accepts all those binary strings in which the number of 1's and 0's are respectively.



(A) Divisible by 3 and 2
(B) Odd and even
(C) Even and odd
(D) Divisible by 2 and 5

23. In the automaton below, s is the start state and t is only final state.



Consider the strings

$U = a\ b\ b\ a\ b\ a$

$V = b\ a\ b$ and

$W = a\ a\ b\ b$

Which of the following statement is true?

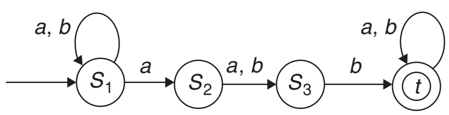
(A) The automaton accepts U and V but not W.

(B) The automaton accepts each of U, V and W.

(C) The automaton rejects U, V and W.

(D) The automaton accepts U but rejects V and W.

24. Which regular expression best describe the language accepted by the non-deterministic automaton below?



(A) $(a + b)^*a(a + b)b$

(B) $(a + b)^*a(a + b)b(a + b)^*$

(C) $(abb)^*$

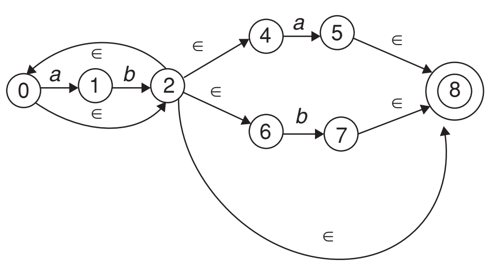
(D) $(a + b)^*$

25. Which of the following strings are accepted by the regular expression:(0/1)* 0(0/1) (0/1)

(A) 000 or 001 (B) 001 or 010

(C) 010 or 011 (D) All the above

26.



The above diagram represents NFA of regular expression.

(A) $(ab)^*\ (a/b/\in)$. (B) $(ab)^*\ (a/b)$.

(C) $(ab)^*\ (a/\in)$. (D) $(ab)^*\ (b/\in)$.

27. If 'a' is a terminal and S, A, B are three (3) non-terminals, then which of the following is regular grammar.

(A) $A \to a\ B/a\ A$ (B) $A \to B\ a/B\ a\ a$

(C) $A \to a\ B$ (D) $S \to \in$
$B \to bA$ $A \to a\ S/b$

28. Consider the grammar

$S \to ABc/Abc$

$BA \to AB$

$Ab \to ab$

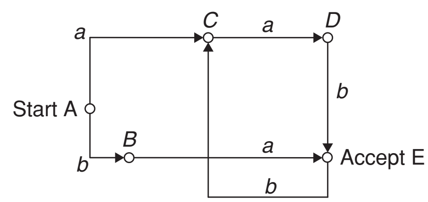
$Aa \to aa$

Which of he following sentences can be derived by this grammar?

(A) aab (B) $abcc$

(C) $abab$ (D) abc

29.



The language recognized by the following finite automation is

(A) $aabb^* + bab^*$

(B) $(aab\ (bab^*))^*$

(C) $(aab + ba)\ (bab)^*$

(D) $(aab^* + bab^*)^*$.

30. From the following regular expressions over an alphabet $\{a, b\}$ given below, which can yield all the possible strings over $\sum (a, b)$?

(i) (a^*b^*)

(ii) $(a + b)^*$

(A) Only (i) (B) Only (ii)

(C) Both (A) and (B) (D) None of these

Theory of Computation Test I

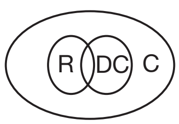
Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

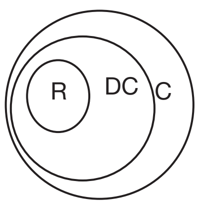
1. Which of the following is FALSE?
I: Any regular language is context free language.
II: There exists a DPDA (Deterministic Push Down Automata) for every CFL.
(A) I only (B) II only
(C) Both I and II (D) Neither I nor II

2. Which of the following figure correctly specifies the relation between regular languages (R), deterministic CFL's (DC) and CFL's (C)?

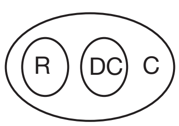
(A)



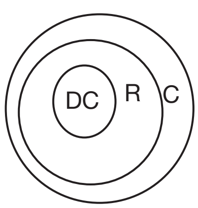
(B)



(C)



(D)



3. Consider the regular expression, $RE = ab^* + ba^*$. Then the reversal of RE, given by RE^R is equal to:
(A) $ab^* + ba^*$ (B) a^*b
(C) $b^*a + a^*b$ (D) $(a^*b)\ (b^*a)$

4. The statement: 'For every regular language L, every subset of L is regular as well' is:
(A) TRUE
(B) False
(C) TRUE, only if L is CFG
(D) False, only if L is CFG.

5. Which of the following strings are not accepted by the language L $(((010 \cup 10)^*1)^*)$?
(A) 1 (B) 0101
(C) 10101110 (D) 01001011

6. Which of the following is FALSE?
(A) $(L_1^*)^* = L_1^*$
(B) $L_1^* = (L_1L_1)^*$
(C) If $L_1 \subset L_2$ then $L_1^* \subset L_2^*$
(D) If L_1 is finite then it is regular.

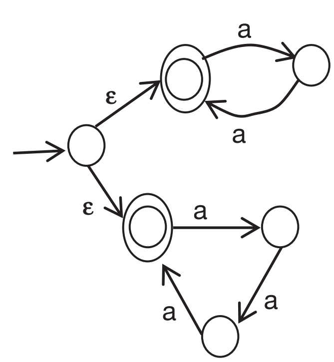
7. Which of the following strings are generated by the regular expression,
$$R = (ab\varepsilon)^*\ (a + b)\ ba?$$
(i) ε (ii) aba
(iii) $ababba$ (iv) $abababa$
(A) (i), (iii) (B) (ii), (iii)
(C) (ii), (iv) (D) (i), (iv)

8. The regular expression $R = (ab\varepsilon)^*\ ((a + b) \cdot \phi)\ ba$ is equivalent to
(A) $(ab\varepsilon)^*\ (a + b)\ ba$ (B) $(ab\varepsilon)^*\ ba$
(C) ba (D) ϕ

9. Which of the following identity is FALSE for regular expressions?
(i) $R + R = R$ (ii) $RR^* = R^*R$
(iii) $\varepsilon R = R\varepsilon = R$
(A) (i), (ii), (iii) (B) (i) only
(C) (ii), (iii) (D) None of these

10. Which of the following language is Regular?
I: $\{ww | w \in \{0, 1\}^*\}$
II: $\{w/w = w^R, w \in \{0, 1\}^*\}$
III: $\{ww^R/w \in \{0, 1^*\}$
IV: Set of all strings with un-equal number of 0's and 1's.
(A) I, III only (B) II, IV only
(C) IV only (D) None of the above

11. Consider the following NFA:

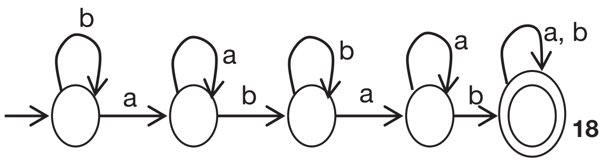


Which of the following gives the language accepted by given NFA?
(A) All strings of the form a^k, $k \geq 0$.
(B) All strings of the form $\{a^m a^n | m \geq 0, n \geq 0\}$
(C) All strings of the form $\{a^m a^n \mid m$ is a multiple of 2 and n is multiple of 3$\}$
(D) All strings of the form $\{a^k \mid k$ is a multiple of 2 or 3$\}$

12. Which of the following is not context-free language?
(i) $\{a^k \mid k$ is a perfect square$\}$

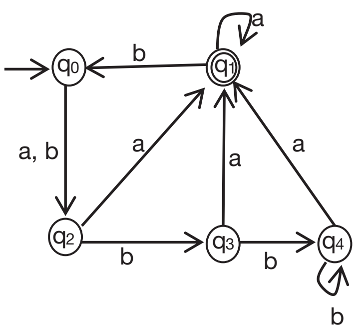
(ii) $\{a^i b^j c^i d^j \mid i, j \geq 0\}$
(iii) $\{a^i b^{2i} a^i \mid i \geq 0\}$
(A) (i), (ii) (B) (ii), (iii)
(C) (i), (iii) (D) (i), (ii), (iii)

13. Consider the following DFA D:



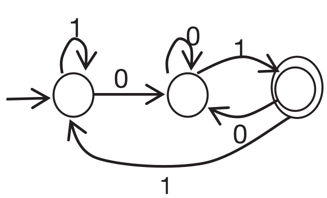
Which of the following is TRUE?
(i) D accepts all strings which contain the sub-word 'ab' two times only.
(ii) D accepts all strings which terminate with 'b'.
(iii) The strings *baabb*, *abbba* are not in the language.
(A) (i), (ii) only (B) (iii) only
(C) (ii), (iii) (D) (i), (iii)

14. Consider the following FA:



Which of the following states are equivalent?
(i) q_0, q_1 (ii) q_2, q_3
(iii) q_3, q_4 (iv) q_0, q_4
(A) (i), (ii) (B) (ii), (iv)
(C) (iii) only (D) (ii), (iii)

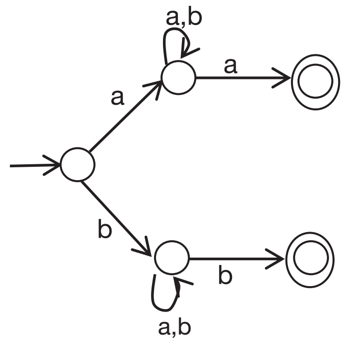
15. Consider the following FA:



The number of states in the minimized FA is
(A) 3 (B) 2
(C) 1 (D) None of the above

16. Which of the following represents a language in automata theory?
(i) Σ^* (ii) ε
(iii) ϕ (iv) $\{\phi\}$
(v) $\{\varepsilon\}$
(A) (i), (iii) only (B) (i), (iii), (v) only
(C) (ii), (iv) only (D) (iv), (v) only

17. Consider the following NFA:



The number of states in its equivalent DFA is
(A) 4 (B) 5
(C) 6 (D) 7

18. Which of the following language is regular?
(i) $\{x = y + z \mid x, y, z$ are binary integers and x is the sum of y and $z\}$
(ii) $\{w \mid w$ is a binary representation of a number greater than 3$\}$
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

19. Consider the following grammar:
S $\rightarrow$ PaP
P $\rightarrow$ ε|PaPbP|PbPaP|Pa|aP
What is the language generated by this grammar over $\{a, b\}$?
(A) Set of all strings with more a's than b's
(B) Set of all strings with more b's than a's
(C) Set of all strings with twice a's than b's
(D) Set of all strings with equal number of a's and b's.

20. Consider a regular language L. A new language DELchar(L) = {W|W is some string from L with exactly one character deleted} is defined. Then DELchar(L) is
(A) a regular language
(B) a CFG but not regular
(C) neither CFG nor regular
(D) not accepted by a PDA

21. Consider the following grammar:
S $\rightarrow$ a Sb | P
P $\rightarrow$ bP | Pa | ε
Which of the following language represents the grammar?
(A) $\{a^n b^n \mid n \in N\}$
(B) $\{a^n b^m b^n \mid m, n \in N\}$
(C) $\{a^n b^m a^p b^n \mid n, m, p \in N\}$
(D) $\{a^n b^m \mid n > m\}$

22. Let M_1 and M_2 are two DFA's with 5-tuple format as given below:

$$M_1 = \{Q_1, \Sigma, \delta_1, S_1, F_1)$$
$$M_2 = (Q_2, \Sigma, \delta_2, S_2, F_2)$$

where Q_1, Q_2 are set of states; Σ is the alphabet set; δ_1, δ_2 are transition functions; S_1, S_2 are start states;

F_1, F_2 are final states. Then which of the following are necessary for $L(M_1) = L(M_2)$?

(i) $Q_1 = Q_2$ (ii) $F_1 = F_2$
(iii) $S_1 = S_2$ (iv) $\delta_1 = \delta_2$
(A) (i), (ii) (B) (i), (ii), (iii)
(C) (i), (ii), (iii), (iv) (D) (iii), (iv)

23. Which of the following language is both regular and context free?

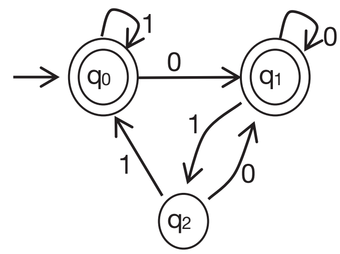
(i) $\{a^n (bc)^n : n \geq 0\}$ (ii) $\{a^n a^n a^n : n \geq 0\}$
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

24. Match the following:

List I		List II	
1	$r^*s + s$	A	r^*
2	ϕ^*	B	ϕ
3	ε^*	C	ε
4	$(\varepsilon + r)^*$	D	$r^* s$

(A) 1–*a*, 2–*b*, 3–*c*, 4–*d*
(B) 1–*d*, 2–*c*, 3–*c*, 4–*a*
(C) 1–*a*, 2–*c*, 3–*c*, 4–*d*
(D) 1–*d*, 2–*c*, 3–*b*, 4–*a*

25. Consider the following FA:



What is the language accepted by above FA?

(A) $\{w|w \in \{0, 1\}^*$ and w do not end with 1$\}$
(B) $\{w|w \in \{0, 1\}^*$ and w contains more zeros than 1's$\}$
(C) $\{w|w \in \{0, 1\}^*$ and w do not end with 01$\}$
(D) $\{w|w \in \{0, 1\}^*$ and w do not have consequent 0's and 1's$\}$

Answer Keys

1. B	**2.** B	**3.** C	**4.** B	**5.** C	**6.** B	**7.** C	**8.** D	**9.** D	**10.** D

21. C	**22.** C	**23.** B	**24.** B	**25.** C					

Hints and Explanations

1. Every regular language is a CFL but not vice versa. Every CFL has a PDA but that PDA need not be a deterministic PDA. Choice (B)

2. Regular $\subset$ DCFL $\subset$ CFL Choice (B)

3. Given regular expression,

$$RE = ab^* + ba^*$$
$$RE^R = (ab^* + ba^*)^R$$
$$= (ab^*)^R + (ba^*)^R$$
$$= (b^*)^R a^R + (a^*)^R b^R$$
$$= (b^R)^*a + (a^R)^*b$$
$$= b^*a + a^*b$$

Choice (C)

4. Given statement is false.
Ex: $L = \{a, b\}^*$; subset of L is $\{a^n b^n \mid n \in N\}$, which is not regular. Choice (B)

5. Given language,

$$L(((010 \cup 10)^*1)^*)$$

The regular expressions which are accepted by 'L' are of the form $((m)^*1)^*$, where $m = 010 \cup 10$.
Any string in L is either ε or ends with '1'. Choice (C)

6. $L_1^* = (L_1 L_1)^*$ is false.
Let $L_1 = \{a\}$ then L_1^* will have 'a' but $(L_1 L_1)^*$ do not have 'a'.
Choice (B)

7. Given regular expression,

$$R = (abe)^* (a + b) ba$$

'ε' is not accepted.
'*aba*' is accepted.
'*ababba*' is not accepted.
'*abababa*' is accepted. Choice (C)

8. $\phi R = R\phi = \phi$, so $(a + b)\phi = \phi$
$\phi \cdot ba = \phi$, $(ab\varepsilon)^* . \phi = \phi$ Choice (D)

9. All the three are valid identities of regular expressions. Choice (D)

10. None of the four languages is regular. Finite automata cannot check the equality of two substrings of a string. Choice (D)

11. Given NFA accepts number of a's which is a multiple of 2 or 3. Choice (D)

12. $\{a^k \mid k$ is a perfect square$\}$
This is not context-free. The PDA can't check whether a number is perfect square or not.
$\{a^i b^j c^i d^j \mid i, j \geq 0\}$
Not context free. PDA can check the equality of a, b and c, d or a, d and b, c but not a, c and b, d.
$\{a^i b^{2i} a^i \mid i \geq 0\}$ is also not recognized by a PDA.
Choice (D)

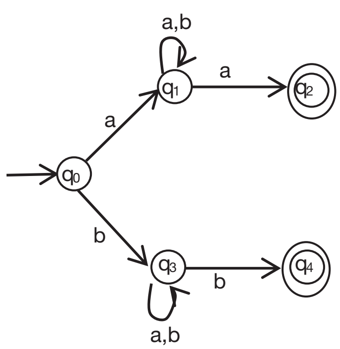
13. Given DFA accepts all strings which contain at least two sub-words '*ab*'. It do not accept *baabb*, *abbba*. Choice (B)

14. In given FA, non-final states are $\{q_0, q_2, q_3, q_4\}$ and final state is $\{q_1\}$.
A state is equivalent to another state if both are either non-final or final states.
Also each transition from those states leads to either final state or non final state only.
$\therefore q_0, q_1$ are not equivalent.
q_0, q_4, are not equivalent.
q_2, q_3 are equivalent as both are non-final states and q_2, q_3 with '*a*' reaches a final state and q_2, q_3 with '*b*' reaches a non-final state.
Similarly, q_3, q_4 are also equivalent. Choice (D)

15. Given FA is the minimal FA. No minimization is possible. ($\because$ With transition '1', both the non-final states are reaching a final and non-final state). Choice (A)

16. Σ^*, ϕ(empty), $\{\varepsilon\}$ are languages. Choice (B)

17. Given NFA,



The DFA equivalent to given NFA is given as,

	a	b
$\to [q_0]$	$[q_1]$	$[q_3]$
$[q_1]$	$[q_1, q_2]$	$[q_1]$
$[q_3]$	$[q_3]$	$[q_3, q_4]$
$[q_1, q_2]$	$[q_1, q_2]$	$[q_1]$
$[q_3, q_4]$	$[q_3]$	$[q_3, q_4]$

$\therefore$ Number of states in the equivalent DFA is 5. Choice (B)

18. (i) is not regular. (This will be shown using pumping Lemma). (ii) is regular and the expression is given as $0^*1\ (0 + 1)\ (0 + 1)\ (0 + 1)^*$ Choice (B)

19. Given grammar is

$$S \to PaP$$
$$P \to e|PaPbP|PbPaP|Pa|aP$$

Consider some derivations:

1. $S \to PaP$
   $\to a$
2. $S \to PaP$
   $\to PaaP$
   $\to aa$
3. $S \to PaP$
   $\to PaPbPaP$
   $\to aba$
4. $S \to PaP$
   $\to baa$

$\therefore$ More *a*'s than *b*'s. Choice (A)

20. DELChar (L) is a regular language. Choice (A)

21. Given grammar,

$$S \to aSb|P$$
$$P \to bP|Pa|e$$

The strings generated by given grammar are
$S \to P$
$\to \varepsilon$
$S \to aSb$
$\to aPb$
$\to ab$
$S \to a\ Sb$
$\to aPb$
$\to aPab$
$\to aab$
$S \to aSb$
$\to aPb$
$\to abPb$
$\to abb$
$S \to aSb$
$\to aaSbb$
$\to aabbb$
In the starting and end of the string we need to have equal number of *a*'s and *b*'s. in between there will be any number of *b*'s and *a*'s.
$\therefore$ The language accepted by given grammar is $\{a^n\, b^m\, a^p\, b^n \mid n, m, p \in N\}$. Choice (C)

22. $L(M_1) = L(M_2)$ if $Q_1 = Q_2$; $F_1 = F_2$; $S_1 = S_2$; $\delta_1 = \delta_2$. Choice (C)

23. (i) is CFL but not regular.
(Checking the equality of *a*'s and (*bc*) is not done using FA)
(ii) is regular and CFL.
$\{a^{3n} \mid n \geq 0\}$ is regular.
Every regular language is CFL. Choice (B)

24.
$$r^*\, s + s = r^*s$$
$$\phi^* = \varepsilon^* = \varepsilon$$
$$(\varepsilon + r)^* = r^*$$
Choice (B)

25. Given FA do not accept the strings which will terminate with '01'. Choice (C)

Theory of Computation Test 2

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Which of the following is TRUE for Turing Machines?
   (i) Turing machines accepts Type-0 languages.
   (ii) Turing machines are used for computing functions.
   (iii) Turing machines are used for determining the undecidability of certain languages.
   (A) (i), (ii) only (B) (i), (iii) only
   (C) (ii), (iii) only (D) (i), (ii), (iii)

2. Which of the following operations are not performed on Turing machines?
   (A) Writing a new symbol in the cell being currently scanned.
   (B) Moving to the cell left of the present cell.
   (C) Moving to the cell right of the present cell.
   (D) None of the above

3. If the languages L_1 and L_2 are decidable then which of the following are also decidable?
   (i) $\bar{L}_1 \cup \bar{L}_2$ (ii) $\bar{L}_1 \cap \bar{L}_2$
   (A) (i) only (B) (ii) only
   (C) Both (i) and (ii) (D) Neither (i) nor (ii)

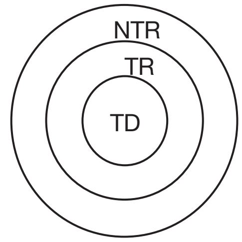
4. If L_1 and L_2 are Turing-recognizable languages then which of the following are not Turing-recognizable?
   (i) $L_1 \cup L_2$ (ii) $L_1 \cap L_2$
   (iii) $L_1 - L_2$ (iv) $\bar{L}_1$
   (v) L_1^* (vi) $L_1 \circ L_2$
   (A) (iv), (v) (B) (iii), (iv)
   (C) (i), (ii), (vi) (D) (ii), (iv), (v)

5. Which of the following statement is FALSE?
   (A) The set of decidable languages is closed under symmetric difference.
   (B) If L_1 is undecidable and L_2 is decidable then the symmetric difference of L_1 and L_2 is undecidable.
   (C) The intersection of a recognizable language and an unrecognizable language is always unrecognizable.
   (D) All of the above

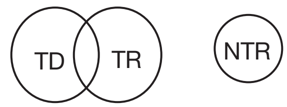
6. If L_1 and L_2 are recursive languages, then which of the following also belongs to recursive languages?
   (i) $L_1 \cup L_2$
   (ii) $L_1 L_2$
   (iii) $\bar{L}_1$
   (A) (i) only (B) (i), (ii)
   (C) (ii), (iii) (D) (i), (ii), (iii)

7. Which of the following correctly specifies the relation between Turing decidable (TD), Turing recognizable (TR) and 'not Turing recognizable' (NTR) languages?

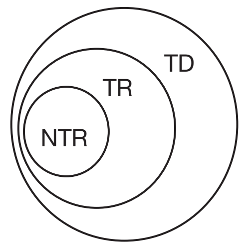
(A)



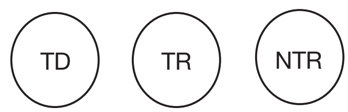
(B)



(C)



(D)



8. Which of the following DFA problems are Decidable?
   (A) The language of all DFA's with an empty language.
   (B) The language of all pairs of DFA's that have the same language.
   (C) $A_{DFA} = \{<D, \omega>|D$ is a DFA, ω is a word and D accepts $\omega\}$
   (D) All of the above

9. Which of the following language is accepted by a Turing machine?
   (i) $\{a^n \# a^n \# a^n : n \geq 0\}$ and $\Sigma = \{a, \#\}$
   (ii) $\{a^n \# b^{2^n} : n \geq 0\}, \Sigma = \{a, b\}$
   (A) (i) only (B) (ii) only
   (C) Both (i) and (ii) (D) Neither (i) nor (ii)

10. For which of the following languages, no Turing-machines will exist?
   (A) Recursive languages
   (B) Recursively-enumerable languages
   (C) Non-Recursively enumerable.
   (D) None of the above

11. If L_1 is a recursive language and L_2 is a recursively enumerable language then which of the following is also recursively enumerable?
   (i) $L_1 \cup L_2$ (ii) $L_1 \cap L_2$
   (iii) $L_1 L_2$ (iv) $L_1 - L_2$
   (v) $L_2 - L_1$
   (A) (i), (ii), (iii) (B) (i), (iii), (iv)
   (C) (iii), (iv), (v) (D) (i), (ii), (iii), (v)

12. Which of the following is False, if A is mapping reducible to B?
(A) If B is decidable then A is decidable.
(B) If B is recursively enumerable then A is recursively enumerable.
(C) If A is undecidable then B is undecidable.
(D) None of the above

13. Which of the following language is Recursive?
(A) $L_1 = \{<M>|M$ is a TM and there exists an input on which M halts in less than $|<M>|$ steps.$\}$
(B) $L_2 = \{<M> \mid M$ is a TM and $|L(M)| \le 3\}$
(C) $L_3 = \{<M> \mid M$ is a TM and $|L(M)| \ge 3\}$
(D) All of the above

14. The language $\{<M> \mid M$ is a Turing machine and $L(M)$ is finite$\}$ is
(A) recursive
(B) recursively enumerable
(C) not recursively-enumerable
(D) decidable

15. Which of the following problem is Recursive?
(i) $\{<M> \mid M$ is a DFA and $L(M)$ is finite$\}$
(ii) $\{<M> \mid M$ is a DFA and $L(M) = \Sigma^*\}$
(iii) $\{<M, x> \mid M$ is a DFA and M accepts $x\}$
(A) (i), (ii) (B) (iii) only
(C) (ii), (iii) (D) (i), (ii), (iii)

16. Which of the following is not accepted by a PDA but accepted by a TM?
(A) $\{a^n b^n c a^n b^n \mid n > 0\}$
(B) $\{a^n b^{2n} c^{3n} \mid n \ge 0\}$
(C) $\{a^n b^{n+m} c^m \text{d}^m \mid m, n \ge 0\}$
(D) All of the above

17. Which of the following has same power as Turing machine?
(A) NDFA (B) 2-PDA
(C) k-tape TM (D) Both (B) and (C)

18. The language $L = \{a^n b^n c^n \mid n \ge 0\}$ can be accepted by a:
(i) 2-PDA (ii) TM
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

19. If $A \le_m B$ (i.e., A is reducible to B) and if B is regular language then does it implies that A is a regular language?
(A) Yes
(B) No
(C) Data insufficient
(D) Reduction is not possible with regular languages.

20. If a language L is recursively enumerable and $L \le_m \overline{L}$ then, which of the following is TRUE?
(A) L is recursive
(B) L may or may not be recursive
(C) L is undecidable
(D) None of these

21. Which of the following language(s) is/are undecidable?
$L_1 = \{<M> \mid M$ is a TM and $L(M)$ is a CFL$\}$
$L_2 = \{<M> \mid M$ is a TM and $L(M)$ is finite$\}$
(A) L_1 only (B) L_2 only
(C) Both L_1 and L_2 (D) Neither L_1 nor L_2

22. For which of the following language(s) a Turing machine exists?
(i) $\varnothing$ (ii) $\{\varepsilon\}$
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

23. A language L is recursive if
(A) L is recursively enumerable.
(B) $\overline{L}$ is recursively enumerable.
(C) Both L and $\overline{L}$ are recursively enumerable.
(D) L is not recursively enumerable.

24. If a Language L is recursively enumerable but not recursive then $\overline{L}$
(A) is recursive
(B) is recursively enumerable
(C) is not recursively enumerable
(D) is decidable

25. A decision problem is undecidable if
(i) it has no algorithm to solve
(ii) it has no TM that halts on every input
(iii) it specifies a language which is not recursive.
(A) (i), (ii) (B) (ii) only
(C) (i), (iii) (D) (i), (ii), (iii)

Answer Keys

1. D	**2.** D	**3.** C	**4.** B	**5.** C	**6.** D	**7.** A	**8.** D	**9.** C	**10.** C
11. D	**12.** D	**13.** A	**14.** C	**15.** D	**16.** D	**17.** D	**18.** C	**19.** B	**20.** A
21. C	**22.** C	**23.** C	**24.** C	**25.** D					

Hints and Explanations

1. Turing machines accepts type-0 languages. They are used for computing functions and for determining the undecidability of languages. Choice (D)
2. A Turing machine can write into some cell, move left or right. Choice (D)
3. If a language is decidable then its complement is also decidable.
   The union and intersection of two decidable languages is also decidable. Choice (C)
4. Turing-recognizable languages (i.e. Recursively-enumerable) are not closed under subtraction and complement operations. Choice (B)
5. Decidable languages are closed under symmetric difference.
   If L_1 is undecidable and L_2 is decidable then the difference of L_1 and L_2 is undecidable.
   Let L_1 is a recognizable language and $L_1 = \emptyset$, L_2 is unrecognizable. Then $L_1 \cap L_2 = \emptyset$ which is recognizable.
   Choice (C)
6. Recursive languages are closed under union, intersection, complementation, concatenation and Kleene closure. Choice (D)
7. Regular $\subset$ Context-free $\subset$ TD $\subset$ TR $\subset$ NTR.
   Choice (A)
8. Some of the decidable properties of DFA are
   - Universality
   - Kleene-closedness
   - Inclusion
   - Disjointness
   - Membership
   - Emptyness
   - Equivalance

   ∴ All the problems in given choices are Decidable.
   Choice (D)
9. A TM can be designed to accept, $\{a^n \# a^n \# a^n\}$. In the input write x for an 'a'. Traverse till # and again write x for an 'a' and traverse till next # and write x for an 'a'. Traverse left till left most x and repeat this for next 'a'. If no more a's left in any part, accept the language.
   Similarly, a TM can be constructed for $\{a^n \# b^{2^n} : n \geq 0\}$. Replace a with x and traverse till # and replace n b's with x and traverse left till x and repeat this. If no more symbols left then accept the language. Choice (C)
10. Recursive: TM always halts.
    Recursively enumerable: TM either halts or halts in non-final state or loops.
    Non-Recursively-enumerable: No TM exists.
    Choice (C)
11. $L_1 - L_2$ is not recursively enumerable. Choice (D)
12. If A is a mapping reducible to B, then based on some basic Theorems,
    - B is decidable then A is decidable
    - A is undecidable then B is undecidable
    - B is Turing-recognizable then A is Turing recognizable.

    ∴ All are TRUE. Choice (D)
13. L_1 is a recursive language. First find the length of M and store it. Then it runs M on all inputs of length atmost $|<M>|$ steps and accepts if M accepts atleast one of the strings within the specified number of steps.
    Choice (A)
14. Given language is not recursively enumerable and undecidable. Choice (C)
15. All the given problems are decidable and hence recursive. Choice (D)
16. $\{a^n\, b^n\, ca^n\, b^n . | n > 0\}$. PDA can check equality of number of a's and b's.
    But it can't able to compare this number of a's and b's with next a's and b's.
    But this can be accepted by a TM. Similarly for $\{a^n\, b^{2n}\, c^{3n} | n \geq 0\}$ and $\{a^n\, b^{n+m}\, c^m\, d^m | \, m, n \geq 0\}$.
    Choice (D)
17. A TM has same power as k-tape TM ($k \geq 1$) and 2-PDA has same power as TM. Choice (D)
18. A 2-PDA (i.e., 2-stack PDA) has same power as TM. A TM can accept L. Choice (C)
19. Given $A \leq_m B$.
    B is regular then it does not imply that A is regular.
    Ex: $\{a^n\, b^n \mid n \geq 0\} \leq_m \{a^n \mid n \geq 0\}$. Choice (B)
20. Given L is recursively enumerable and $L \leq_m \bar{L}$.
    As $L \leq_m \bar{L}$ then $\bar{L} \leq_m L$.
    ($\because A \leq_m B$ then $\bar{A} \leq_m \bar{B}$).
    L is RE, so $\bar{L}$ is also RE. As both L and $\bar{L}$ are RE then L is recursive. Choice (A)
21. $\{<M, w>$: M is a TM and M accepts input string $w\}$ is a known undecidable problem. We can reduce this to L_1 and L_2 also. So both L_1 and L_2 are undecidable.
    Choice (C)
22. A TM can exist for both languages. (i) rejects everything. (ii) accepts '$\in$' only. Choice (C)
23. If a language L and its complement $\bar{L}$ are recursively enumerable, then L is recursive. Choice (C)
24. Both L and $\bar{L}$ are recursively enumerable if L is recursive. Choice (C)
25. An undecidable problem has no algorithm, no TM and is also not recursive. Choice (D)

Chapter 1

Processes and Threads

LEARNING OBJECTIVES

- *Basics of operating systems*
- *Services of OS*
- *Evolution of operating systems*
- *Processes*
- *Processes and process control blocks*
- *Process states*
- *Process creation*
- *Suspended processes*
- *OS control structures*
- *Process attributes*
- *Modes of execution*
- *Threads*
- *Thread functionality*
- *Thread synchronization*

Basics of Operating System

An operating system (OS) is a program that controls the execution of application programs and acts as an interface between applications and the computer hardware. The three objectives of an OS are as follows:

1. *Convenience*: An OS makes a computer more convenient to use.
2. *Efficiency*: An OS allows the computer system resources to be used in an efficient manner.
3. *Ability to evolve*: An OS should be constructed in such a way as to permit the effective development, testing and introduction of new system functions without interfering with service.

OS as a User–Computer Interface

Consider the below figure (Figure 1) which shows the hardware and software used in providing applications to a user in a layered fashion.

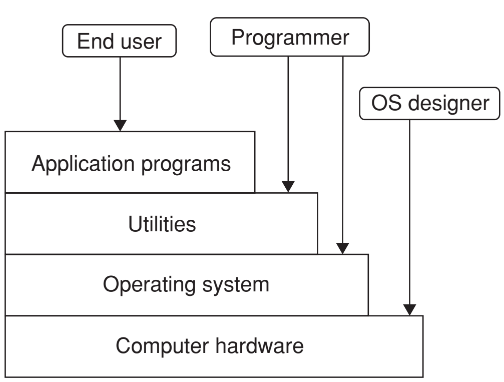


Figure 1 Layers and views of a computer system.

The end user of the application is not concerned with the details of computer hardware. Utilities implement the frequently used functions that assist in program creation, the management of files and control of input/output (I/O) devices. The most important collection of system programs comprises the OS. The OS masks the details of the hardware from the programmer and provides the programmer with a convenient interface for using the system.

Services of an OS

1. *Program development*: An OS provides a variety of facilities and services as editors and debuggers to assist programmers in creating programs.
2. *Program execution*: An OS handles the scheduling duties of program execution for the user.
3. *Access to I/O devices*: An OS provides a uniform interface that hides the details of I/O devices so that the programmers can access the I/O devices using simple reads and writes.
4. *Controlled access to files*: In a system with multiple users, an OS provides protection mechanism to control access to the files.
5. *System access*: For shared or public systems, an OS controls access to the system as a whole and to specific system resources.
6. *Error detection and response*: An OS must provide a response that clears the error condition with the least impact on running applications.
7. *Accounting*: A good OS will collect usage statistics for various resources and monitor performance parameters (viz., response time).

OS as Resource Manager

A computer is a set of resources for the movement, storage and processing of data and for the control of these functions. An OS is responsible for managing these resources.

1. An OS functions in the same way as ordinary computer software, that is, it is a program or suite of programs executed by the processor.
2. An OS frequently relinquishes control and must depend on the processor to allow it to regain control.

The OS directs the processor in the use of the other system resources and in the timing of its execution of other programs.

Figure 2 shows the resources that are managed by an OS.

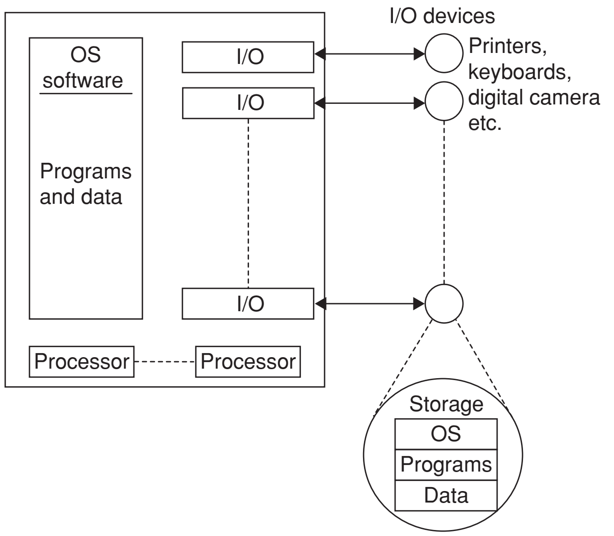

Figure 2 OS as a resource manager.

A portion of the OS lies in the main memory. This includes the kernel or nucleus, which contains the most frequently used functions in the OS and, at a given time, other portions of the OS currently in use. The remainder of main memory contains user programs and data. The allocation of this resource is controlled jointly by the OS and memory management hardware in the processor.

Evolution of OSs

Serial processing

With the earliest computers, the programmer interacted directly with the computer hardware. There was no OS. Programs in machine code were loaded via the input devices. This mode of operation is termed as *serial processing*. Problems with this system are scheduling and setup time.

Simple batch systems

- It requires the grouping up of similar jobs, which consist of programs, data and system commands.
- Users have no control over results of a program.
- Off-line debugging.

Multiprogrammed batch systems

In view of simultaneous execution of multiple programs, it improves system throughput and resource utilization.

Example: Windows XP, 98

- **Multitasking OS:** A running state of a program is called a *process* or a *task*. The concept of managing a multitude of simultaneously active programs, competing with each other for accessing the system resources is called *multitasking*.
- Serial multitasking or context switching is the simplest form of multitasking.

Example: Windows NT, Linux

- **Multiuser OS:** It is defined as multiprogramming OS that supports simultaneous interaction with multiple users.

Example: Linux, Unix, a dedicated transaction processing system (viz., railway reservation system).

- **Multiprocessing OS:** The term *multiprocessing* means multiple CPUs performing more than one job at one time.

The term 'multiprogramming' means situation in which a single CPU divides its time between more than one job.

Time sharing systems

In this kind of OS, the processor time is shared among multiple users. The CPU switches rapidly from one user to another user; each user is given an impression that he/she has his own computer while it is actually one computer shared among many users.

If there are n users actively requesting service at one time, each user will only see on the average $1/n$ of the effective computer capacity, not counting OS overhead.

Bootstrap Bootstrap is an initial program which runs, when a computer is powered up (or) restarted. The task is to initialize system aspects (CPU registers to device controllers to memory contents). It is stored within the computer hardware known as *firm ware* (EEPROM).

Processes

Processes and Process Control Blocks

Process A process is an instance of a program in execution. Two essential elements of a process are as follows:

1. Program code
2. Set of data

At any given point in time, while the program is executing, the process can be uniquely characterized by a number of elements, including the following:

1. Identifier
2. State
3. Priority

4. Program counter
5. Memory pointers
6. Context data
7. I/O status information
8. Accounting information

This information is stored in a data structure, typically called a *process control block*, that is created and managed by the OS.

Process control block (PCB) It contains sufficient information so that it is possible to interrupt a running process and later resume execution as if the interruption has not occurred.

Process States

The behaviour of an individual process can be characterized by listing the sequence of instructions that executed for that process. This listing is referred to as a *trace* of the process. Also the behaviour of a processor is shown by listing the traces of the various processes that are interleaved.

Dispatcher A dispatcher is a small program that switches the processor from one process to another.

Two-state process model In the simplest possible process model (Figure 3), at any time, a process is either being executed by a processor or not, that is, a processor may be in one of two states: *running* or *not running*.

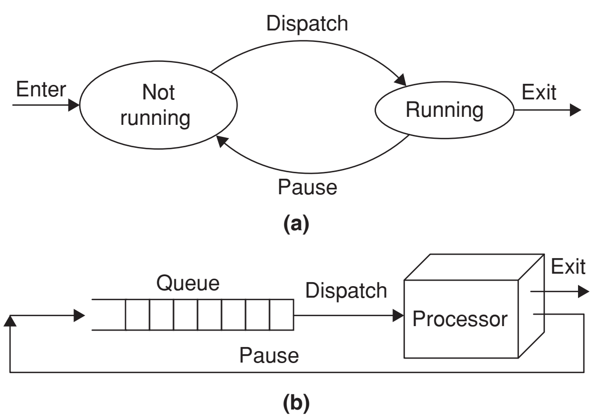

Figure 3 Two-state process model. (a) State transition diagram, (b) Queuing diagram

When the OS creates a new process, it creates the PCB for the process and enters that process into the system in the *not running* state. The process exists, is known to the OS, and is waiting for an opportunity to execute. From time to time, the currently running process will be interrupted and the dispatcher portion of the OS will select some other process to run. The former process moves from the *running* state to the *not running* state and one of the other processes moves to the *running* state.

Processes that are not running must be kept in some sort of queue, waiting their turn to execute. Figure 3(b) shows the structure. There is a single *queue* in which each entry is a pointer to the PCB of a particular process.

Creation and Termination of Processes

Process creation

When a new process is to be added to those currently being managed, the OS builds the data structures that are used to manage the process and allocates address space in main memory to the process. The common events which lead to process creation are as follows:

1. New batch job
2. Interactive logon
3. Created by OS to provide a service
4. Spawned by existing process

When the OS creates a process at the explicit request of another process, the action is referred to as *process spawning*. When one process spawns another, the former is referred to as the *parent process* and the spawned process is referred to as the *child process*.

Process termination

The following are the reasons for process termination:

1. *Normal completion*: Process executes an OS service call to indicate its completion.
2. *Time limit exceeded*: The process has run longer than the specified total time limit.
3. *Memory unavailable*: The process requires more memory than the system can provide.
4. *Bounds violation*: The process tries to access a memory location that it is not allowed to access.
5. *Protection error*: The process attempts to use a resource that is not allowed to access.
6. *Arithmetic error*: The process tries a prohibited computation.
7. *Time overrun*: The process has waited longer than a specified maximum for a certain event to occur.
8. *I/O failure:* Error occurs during input or output.
9. *Invalid instruction*: The process attempts to execute a non-existent instruction.
10. *Privileged instruction*: The process attempts to use an instruction reserved for OS.
11. *Data misuse*: A piece of data is of the wrong type or is not initialized.
12. *Operator or OS intervention.*
13. *Parent termination.*
14. *Parent request.*

Five-state model

The five states in Figure 4 are as follows:

1. *New*: The process is created but not admitted to the pool of executable processes.
2. *Running*: Process in execution, that is, it is using CPU.
3. *Blocked*: Waiting for some event to occur (i.e., I/O) before it can continue execution.

4. *Ready*: Process is ready for execution. Just it is waiting.
5. *Exit*: The process has been aborted by parent process or has finished its execution.

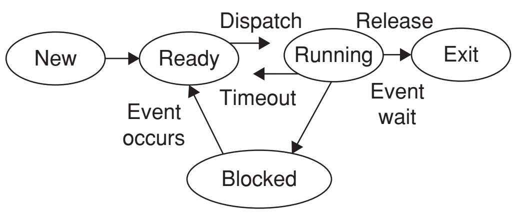

Figure 4 Process states.

Figure 4 indicates the types of events that lead to each state transition for a process. The possible transitions are as follows:

1. NULL → New: A new process is created to execute a program.
2. New → Ready: The OS will move a process from the New state to the Ready state when it is prepared to take on an additional process.
3. Ready → Running: When it is time to select a process to run, the OS chooses one of the processes in the Ready state.
4. Running → Exit: The currently running process is terminated by the OS if the process indicates that it has completed or if it aborts.
5. Running → Ready: The reasons for this transition are
   - Running process has reached the maximum allowable time for uninterrupted execution.
   - As the OS assigns different levels of priority to different processes, there will be pre-emption.
   - A process may voluntarily release control of the processor.
6. Running → Blocked: A process is put in the blocked state if it requests something for which it must wait.
7. Blocked → Ready: This transition occurs when the event for which the process has been waiting occurs.
8. Ready → Exit: A parent may terminate a child process at any time.
9. Blocked → Exit: Parent may terminate any blocked process.

Queuing model for five-state model

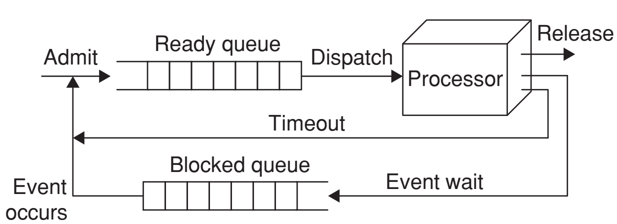

Figure 5 Single blocked queue.

Suspended Processes

Need for swapping In five-state process model using multiple blocked queues, the memory holds multiple processes. Moreover, the processor can move to another process when one process is blocked. But the processor is so much faster than I/O that it will be common for all of the processes in memory to be waiting for I/O. Thus, even with multiprogramming, a processor could be idle most of the time.

Then we can extend the main memory to accommodate more processes, but it is not an efficient solution. Another solution to this problem is swapping. Swapping involves moving part or all of a process from main memory to disk. When none of the processes in main memory is in the ready state, the OS swaps one of the blocked processes out onto disk into a suspend queue. The OS then brings in another process from the suspend queue or it honours a new process request. Then execution continues with the newly arrived process. With the use of swapping, another state is added to the process in the behaviour model.

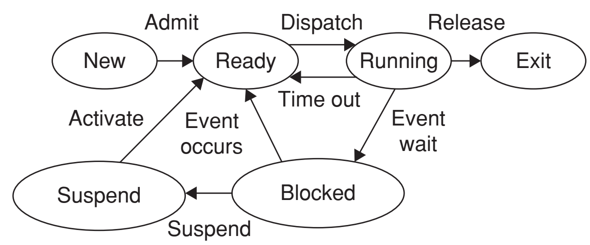

Figure 6 Process state-transition diagram with suspend state.

The four distinguishable states in this process model are as follows:

1. *Ready*: The process is in main memory and is available for execution.
2. *Blocked*: The process is in main memory and awaiting an event.
3. *Blocked/suspend*: The process is in secondary memory and awaiting an event.
4. *Ready/suspend*: The process is in secondary memory but is available for execution as soon as it is loaded into main memory.

Figure 7 shows the process state model with two suspend states:

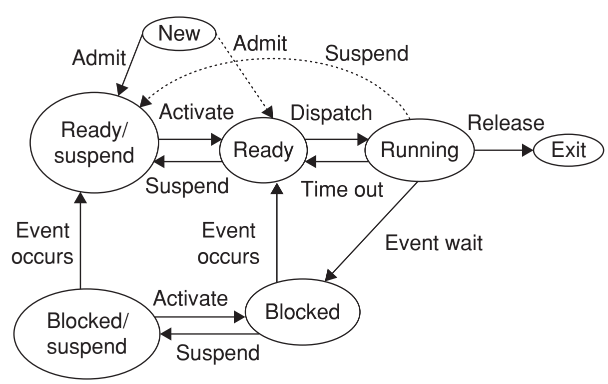

Figure 7 Process state transition diagram with suspend state.

Uses of Suspension

Characteristics of suspended process are as follows:

1. The process is not immediately available for execution.
2. The process may or may not wait on an event.
3. The process was placed in a suspend state by either itself, a parent or the OS.

Reasons for process suspension

- *Swapping*: To Release sufficient main memory.
- *Other OS reason*: OS may suspend a background process.
- *Interactive User Request*: A user may wish to suspend execution of a program.
- *Timing*: A process may be executed periodically and may be suspended.
- *Parent Process request*: A parent process may wish to suspend execution of a descendent.

OS Control Structures

If the OS is to manage processes and resources, it must have information about the current status of each process and resources. The OS constructs and maintains tables of information about each entity that it is managing. Figure 8 shows the general structure of OS control tables:

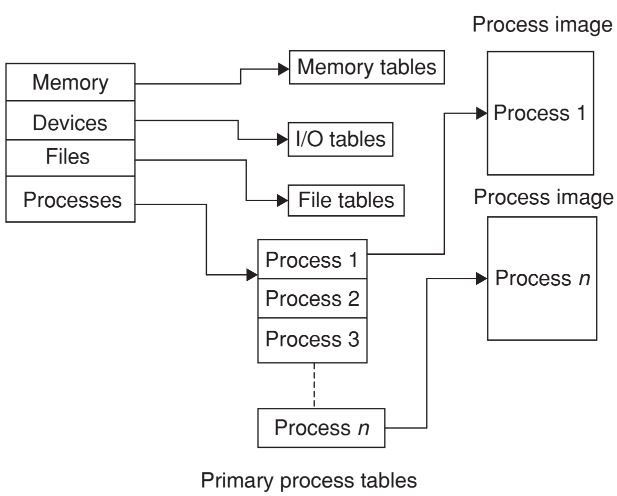

Figure 8 OS control tables.

Different tables maintained by the OS are

1. Memory
2. I/O
3. File
4. Process

Memory tables: These tables are used to keep track of both main and secondary memory.

I/O tables: These are used by the OS to manage the I/O devices and channels of the computer system.

File tables: These tables provide information about the existence of files, their location on secondary memory, their current status and other attributes.

Process tables: An OS must maintain process tables to manage processes.

Process Control Structures

The OS must know about

1. Process location
2. Process attributes

Process Location

The collection of program, data, stack and attributes is referred as process image.

The location of a process image will depend on the memory management scheme being used. The process image is maintained as a contiguous or continuous block of memory. This block is maintained in secondary memory, usually disk, so that the OS can manage the process, at least a small portion of its image must be maintained in main memory. To execute the process, the entire process image must be loaded into main memory or at least virtual memory. Thus the OS needs to know the location of each process on disk and for each such process that is in the main memory, the location of that process is in main memory.

For this, the OS maintains process tables. There is a primary process table with one entry for each process. Each entry contains, at least, a pointer to a process image.

Process Attributes

The typical information required by the OS for each process is as follows:

1. Process identification
2. Process state information
3. Process control information

Process identification Each process is assigned a unique numeric identifier, which may simply be an index into the primary process table. The identifier for a PCB includes the following:

1. Identifier of the process
2. Identifier of the process that created current process
3. User identifier

Process state information It consists of the contents of processor registers. It includes details of

1. User-visible register
2. Control and status registers
3. Stack pointers

Process control information It consists of the additional information needed by the OS to control and coordinate the various active processes. It includes the following:

1. Scheduling and state information
2. Data structuring
3. Interprocess communication

4. Process privileges
5. Memory management
6. Resource ownership and utilization

Process Control

Modes of Execution

Most processors support at least two modes of execution as follows:

1. More-privileged mode
2. Less-privileged mode

Two modes are required to protect the OS and key OS tables from interference by user programs.

1. ***More-privileged mode:*** This is also referred as *system mode*, *control mode* or *kernel mode*. Certain instructions can only be executed in Kernel mode (e.g., reading or altering a control register, viz., PSW, primitive I/O instructions, etc.).

   The Kernel of the OS is a portion of the OS and encompasses the important system functions.

   The functions of an OS kernel are as follows:
   - Process management
   - Memory management
   - I/O Management
   - Support functions
2. ***Less-privileged mode:*** This is also referred as *user mode*, because user programs typically would execute in this mode.

   In this mode, the software has complete control of the processor and all its instructions, registers and memory.

Process creation If the OS decides to create a table, it has to proceed as follows:

1. Assign a unique process identifier to the new process.
2. Allocate space for the process.
3. Initialize the PCB
4. Set the appropriate linkages.
5. Create or expand other data structures.

Process switching In process switching, a running process is interrupted and the OS assigns another process to the running state and turns control over to that process. The design issues are as follows:

1. When to switch processes
2. Mode switching
3. Change of process state

When to switch processes A process switch may occur anytime that the OS has gained control from the currently running process. The mechanisms for interrupting the execution of a process are as follows:

1. Interrupt
2. Trap
3. Supervisor call

Interrupt When an interrupt occurs, the control is first transferred to an interrupt handler, which does some basic housekeeping and then branches to an OS routine that is concerned with the particular type of interrupt that has occurred (e.g., clock interrupt, I/O interrupt, memory fault, etc.).

Trap Trap related to an error or exception condition gets generated within the currently running process. If the error is fatal, the currently running process is moved to exit state and a process switch occurs, otherwise the action of the OS will depend on the nature of the error and design of the OS.

Supervisor call The OS may be activated by a supervisor call from the program being executed. The case of system call may place the user process in blocked state.

Mode switching If the processor identifies that any interrupt is pending, then

1. it sets the PC to the starting address of an interrupt handler program.
2. it switches from user mode to Kernel mode so that the interrupt processing code may include privileged instructions.

During this process, the context of the process, that has been interrupted, is saved into that PCB of the interrupted program. The context of a program includes PC, other processor registers and stack information.

The occurrence of an interrupt does not necessarily mean a process switch.

Change of process state The mode switch is a concept distinct from that of the process switch.

A mode switch may occur without changing the state of the process that is currently in Running state. In that case, the context saving and subsequent restoral involve little overhead. However, if the currently running process is to be moved to another state then the OS must make substantial changes in its environment. Thus, the process switch, which involves a state change, requires more effort than a mode switch.

System call In order to access the OS services, an interface is required which is provided by the system call.

All the system call routines are executed in Kernal mode. Whenever the system call is invoked, the process status word is changed from user mode to Kernal mode ($0 \rightarrow 1$).

System calls are of six types as follows:

1. File system
2. Process
3. Scheduling
4. Interprocess communications
5. Socket
6. Miscellaneous

Execution of the OS

There are three possibilities to consider about OS execution:

1. Separate Kernel (Figure 9)
2. OS functions execute within user processes (Figure 10)
3. OS functions execute as separate processes (Figure 11)

Separate Kernel

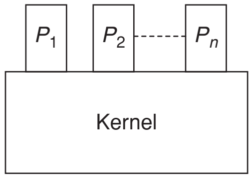

Figure 9 OS as separate Kernel.

Here the Kernel of the OS is executed outside of any process. When currently running process is interrupted or issues a supervisor call, the mode context of this process is saved and control is passed to the Kernel.

Execution within user process

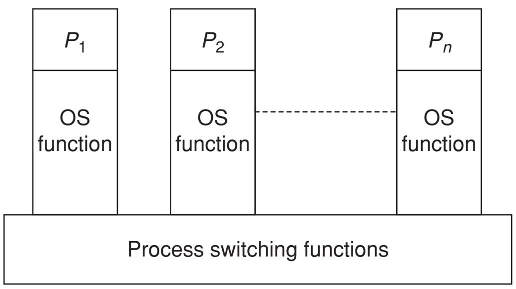

Figure 10 OS functions execute within user processes.

We execute virtually all OS software in the context of user process. To pass control from a user program to the OS, the mode context is saved and a mode switch takes place to an OS routine, that is, a process switch is not performed, just a mode switch within the same process.

Process-based OS

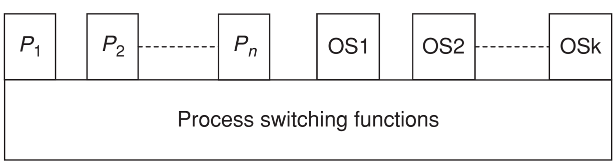

Figure 11 OS functions execute as separate process.

Here the OS is a collection of system processes. This approach encourages the use of modular OS with minimal, clean interface between the modules.

Threads

A *thread* is a basic unit of CPU utilization. It comprises a thread ID, a program counter, a register set and a stack.

Multithreading

It refers to the ability of an OS to support multiple, concurrent paths of execution within a single process.

The threads which belong to same process can share their

1. Code section
2. Data section
3. Other OS resources

If a process has multiple threads of control, it can perform more than one task at a time. Figure 12 shows single threaded and multithreaded process models:

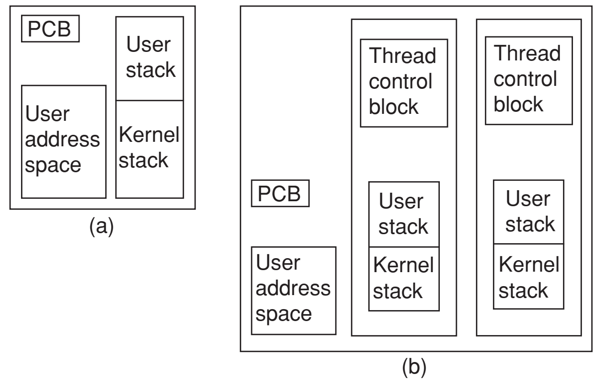

Figure 12 Process models. (a) Single-thread process model (b) Multithreaded process model.

As OS based on its design will be in one of the following manners (Figure 13):

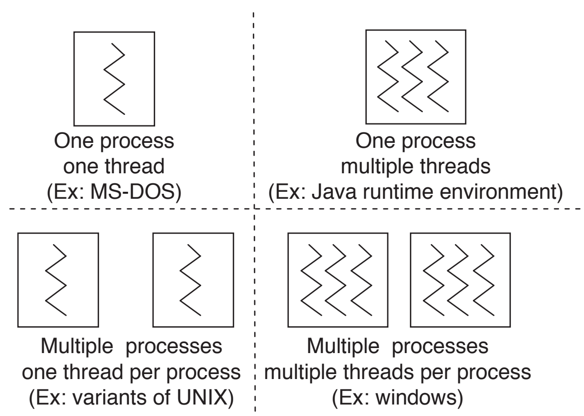

Figure 13 Threads and processes.

The threads of a process consist of the following:

1. Thread execution state.
2. Saved thread context when not running
3. An execution stack
4. Some pre-thread static storage for local variables.
5. Access to the memory and resources of its process, shared with all other threads in that process.

All the threads of a process share the state and resources of that process.

Benefits of multithreaded programming

1. *Responsiveness*: Multithreading an interactive application may allow program to continue running even if

part of it is blocked or is performing a lengthy operation, thereby increasing responsiveness to the user.

2. *Resource sharing*: Threads share the memory and the resources of the process to which they belong by default.
3. *Economy*: It is economical to create a new thread in an existing process than to create a brand-new process. It takes less time to context switch between two threads of same process than to switch between processes. Also the time to terminate a thread is less than process termination.
4. *Scalability*: Multithreading on a multi-CPU machine increases parallelism.

Applications that benefit from thread As the threads take advantages of multiple processors, image processing which can be done in parallel, will execute in threads.

Animation rendering is another thread application, where each frame can be rendered in parallel, as each one is independent of other GUI programming will execute at least two threads when it is processing large number of files.

Applications that cannot benefit from thread The main drawbacks of threads is if kernel is single threaded, system call of one thread will block the whole process, in which CPU will be idle during the blocking period.

The other major drawback is security as it is possible that a thread can overwrite the stack as the other thread, as they were meant to cooperate on a single task. Applications that are developed using PHP does not support multithreading at the server side.

Thread Functionality

The key states for threads are as follows:

1. Running
2. Ready
3. Blocked

There are four basic thread operations associated with a change in thread state:

1. *Spawn*: When a new process is spawned, a thread for that process is also spawned.

   Also, a thread within a process may spawn another thread within the same process.
2. *Block*: When a thread needs to wait for an event, it will block. Then the processor may turn to the execution of another ready thread in the same or different process.
3. *Unblock*: When an event for which a thread is blocked occurs, the thread is moved to Ready queue.
4. *Finish*: When a thread completes, its register context and stacks are deallocated.

Multithreading on a Uni-processor

On a uni-processor, multiprogramming enables the interleaving of multiple threads within multiple processes. For example, consider the execution of three threads A, B, C in two processes on a single processor which are interleaved (Figure 14).

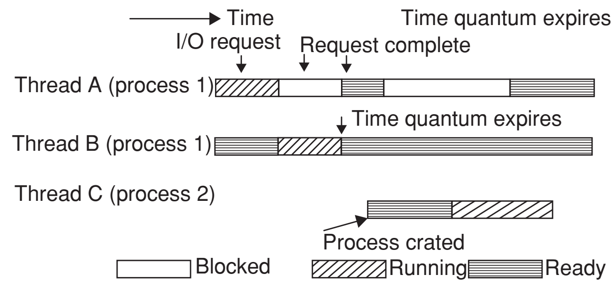

Figure 14 Multithreading on a uni-processor.

Execution passes from one thread to another, either when the currently running thread is blocked or its time slice is exhausted.

Resources used in thread creation and process creations

As process has heavy weight, when it is created, new address space is required, which includes stack, heap and data section, etc. If a process shares the memory, then the IPC is expensive.

The thread is a light-weight process, if it doesn't require any new resources, as it will share the process resources to which it belongs. The major benefit of this is, several threads belong to same activity and can run under same address space.

Thread Synchronization

All of the threads of a process share the same address space and other resources, such as open files. Any alteration of a resource by one thread affects the environment of the other threads in the same process. So, synchronization mechanism is required to coordinate the activities of all the threads within a process.

The techniques used for thread synchronization is the same as process synchronization techniques, which has been discussed later in this book.

Types of Threads

User-Level Threads

All thread management is done by the application. The Kernel is not aware of the existence of threads. Thread creation and scheduling are done in user space. User-level threads (Figure 15) are fast to create and manage. User-level library provides support for creating, managing and scheduling threads. In single-threaded Kernel, blocking system call from user level thread will block the entire process, even if other threads are ready to run.

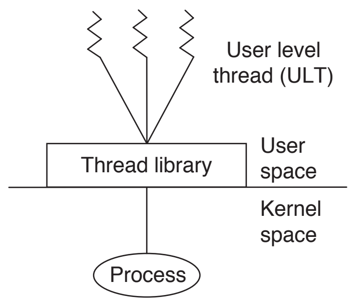

Figure 15 Pure user-level threads.

Advantages of ULTs

1. ULT creation does not require Kernel mode privileges.
2. ULT scheduling can be application specific.
3. ULTs can run on any OS.

Disadvantages of ULTs

1. When a ULT executes a system call, not only is that thread blocked, but also all of the threads within the process are blocked.
2. In a pure ULT strategy, a multithreaded application cannot take advantage of multiprocessing.

Kernel-level Threads

Kernel-level threads (KLTs) are supported directly by the OS. The creation, scheduling, management are done by kernel in kernel space. They are slower to create and manage. In a multiprocessor, Kernel can schedule threads on different processors.

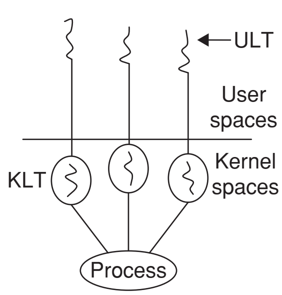

Figure 16 Pure kernel-level threads.

Advantages of KLTs

1. Kernel can simultaneously schedule multiple threads from the same process on multiple processors.
2. If one thread in a process is blocked, the kernel can schedule another thread of the same process.
3. Kernel routines themselves multithreaded.

Disadvantages of KLTs

The transfer of control from one thread to another within the same process requires a mode switch to the Kernel.

Combined Approach

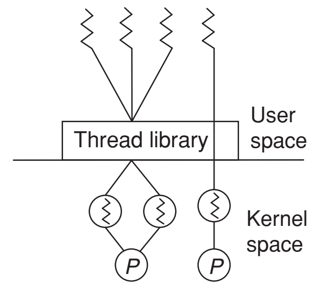

Figure 17 Combined approach.

In combined approach (Figure 17), multiple threads within the same application can run in parallel on multiple processors and a blocking system call need not block the entire process.

Relationship between the threads and processes

1. *One-to-one relationship*: Each thread of execution is a unique process with its own address and resources.
   Example: Traditional UNIX.
2. *Many-to-one relationship*: A process defines an address space and dynamic resources ownership. Multiple threads may be created and executed within that process.
   Example: Windows NT, Solaris, Linux.
3. *One-to-many relationship*: A thread may migrate from one process environment to another. This allows a thread to be easily moved among distinct systems.
   Example: Emerald
4. *Many-to-many relationship*: It combines the attributes of M:1 and 1:M cases.
   Example: TRIX

Threading Issues

fork( ) and exec( ) System Calls

A fork( ) system call is used to create a separate, duplicate process. In UNIX, each process is identified by its process identifier, which is a unique integer. A new process is created by fork( ) system call.

The new process consists of a copy of the address space of the original process. This mechanism allows the parent process to communicate easily with its child process. Both processes continue execution at the instruction after the fork( ), with one difference: the return code for the fork( ) is zero for the new process, whereas the process identifier of the child is returned to the parent. The exec( ) system call is used after a fork( ) system call by one of the two processes to replace the processes memory space with a new program.

If one thread in a program calls fork( ), then UNIX chooses two alternatives as follows:

1. Duplicates all the threads
2. Duplicates only the thread that invoked the fork( ) system call.

If a thread invokes the exec( ) system call, the program specified in the parameter to exec( ) will replace the entire process including all threads.

Cancellation

Thread cancellation is the task of terminating a thread before it has completed. A thread that is to be cancelled is often referred to as the *target thread*. Cancellation of a thread may occur in two different scenarios as follows:

1. *Asynchronous cancellation*: One thread immediately terminates the target thread.
2. *Deferred cancellation*: The target thread periodically checks whether it should terminate, allowing it an opportunity to terminate itself in an orderly fashion.

Microkernels

Microkernel (Figure 18) is a small OS core that provides the foundation for modular extensions.

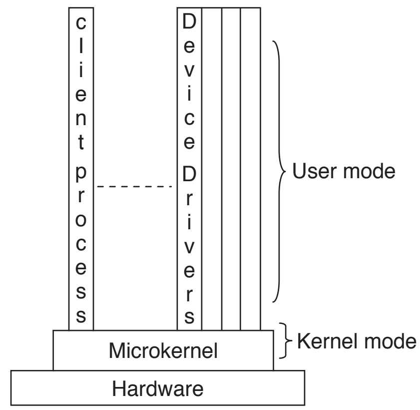

Figure 18 Microkernel architecture.

Advantages of Microkernel Organization

- Uniform interfaces
- Extensibility
- Flexibility
- Portability
- Reliability
- Distributed system support
- Support for object oriented OS

Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. In fork( ) system call, the return value to the parent process and the child process are respectively
(A) PID of child process, 1
(B) PID of child process, 0
(C) PID of child, PID of parent process
(D) PID of parent process, PID of child

2. Which of the following is not an advantage of thread?
(A) Inter process communication
(B) Less memory space occupied by thread
(C) Less time to create and terminate than a process
(D) Context switching is faster

3. A process executes the following segment of code

for (i = 1; i < 10; i ++) fork( );

The number of new processes created is
(A) 1024 (B) 1023
(C) 1025 (D) 1028

4. For each of the following transitions, between process states, which transition is not possible?
(A) Running → Ready
(B) Blocked → Suspend
(C) Ready → Ready/Suspend
(D) Blocked → Running

5. An operating system can be mapped to a five-state process model. A new event has been designated as capable to pre-empt the existing processes in order to trigger a new process to complete. Select the correct statement from below:
(A) A new state need to be added to the existing transition model to accommodate the changes.
(B) The existing model still holds good.
(C) Both the states and transitions of the existing model have to be changed.
(D) Only the transitions need to be modified.

6. The advantage of having multiple threads over multiple processes is
(i) Less time for creation
(ii) Less time for termination
(iii) Less time for switching
(iv) Kernel not involved in communication among threads
(A) (i), (ii), (iii) (B) (i), (ii), (iv)
(C) (ii), (iii), (iv) (D) (i), (ii), (iii), (iv)

7. Select the correct sequence of steps taken by the processor when an interrupt occurs
(i) Switch from user mode to kernel mode.
(ii) Set the program counter to the first instruction of the interrupt handling routine.
(iii) Save the current context.

(A) (i), (ii), (iii)
(B) (i), (iii), (ii)
(C) (iii), (ii), (i)
(D) (ii), (i), (iii)

8. What are the necessary steps for a new process creation?
(i) Assign an identifier to the new process.
(ii) Suspend all other processes.
(iii) Allocate space for the process.
(iv) Initialize process control block.
(v) Update process-related data structures.
(vi) Update process state information wherever necessary.
(vii) Set the process to user mode
(viii) Notify all the machines in the network about the new process.
(ix) Set the state of the new process as suspended

(A) All except (ii), (v), (vi), (viii)
(B) All except (ii), (vii), (viii), (ix)
(C) All except (iv), (v), (vii), (ix)
(D) All except (iii), (iv), (vii), (ix)

9. A processor, while executing the instruction sequence of user mode process, received n interrupts. If no other activity is reported to processor during the execution of the instruction sequence, what is the number of mode switches and process switches experienced?

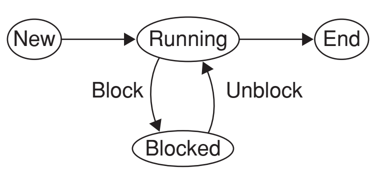
(A) $2n$, $2n$ (B) n, n
(C) $2n$, 0 (D) n, 0

10. Assume a program needs to implement threads, what are the resources that need to be encompassed in critical section?
(i) Global variables
(ii) Local variables
(iii) Static variables
(iv) Function parameters that are passed as reference pointers
(v) Global constants

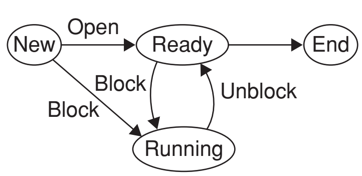
(A) (i), (ii), (iii), (v)
(B) (i), (iv), (v)
(C) (i), (iii), (v)
(D) (i), (iii), (iv)

11. Which of the following is an appropriate four-state model for a process?

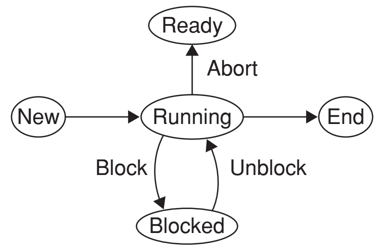
(A)



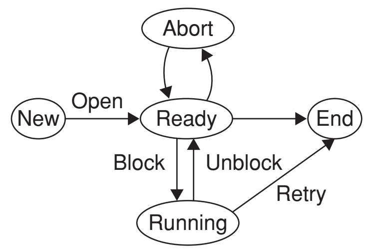
(B)



(C)



(D)



12. Which of the following are considered as disadvantage of user level thread (ULT)?
(i) Calls made from system will block all threads in a process
(ii) When scheduled in a multiprocessing environment only one thread per process can be executed at a time.
(iii) ULTs cannot communicate with each other in a process.
(iv) The cost of creating a thread is high

(A) (i), (ii), (iii) (B) (i), (iii), (iv)
(C) (i), (ii) only (D) (ii), (iii), (iv)

13. Choose from below, advantages of kernel-level threads:
(i) Kernel can simultaneously schedule multiple threads from the same process on multiple processors.
(ii) Kernel routines can be multithreaded.
(iii) If one thread of a process is blocked then kernel can schedule another thread from the same process.

(A) (i) only (B) (i), (ii)
(C) (i), (ii), (iii) (D) (i), (iii)

14. Assume that part of a program takes long time to execute. Select an option from below that can enhance performance:
(i) Implement the part that takes long time as a separate process and use the results as needed from the main program.
(ii) Implement both the parts as two different threads in the same process.

(A) (i) only
(B) (ii) only
(C) Both (i) and (ii)
(D) Neither (i) nor (ii)

15. What is a kernel-level thread?
(i) Threads that are spawned by OS Kernel
(ii) Threads that are launched by user by directly accessing the kernel

(A) (i) only (B) (ii) only
(C) Both (i), (ii) (D) Neither (i) nor (ii)

Practice Problems 2

Directions for questions 1 to 14: Select the correct alternative from the given choices.

1. Many-to-many multithreading model is used in which of the following operating system?
(A) Windows NT/2000 with Thread Fibre
(B) Windows 95
(C) Windows 98
(D) Solaris Green Threads

2. Which of the following does not interrupt a running process?
(A) Device (B) Timer
(C) Scheduler (D) Power failure

3. Which of the following need not be saved on a context switch between processes?
(A) General purpose registers
(B) Translation look aside buffer
(C) Program counter
(D) All of the above

4. Which of the following actions is/are typically not performed by the OS when switching context from process A to process B?
(A) Saving current register values and restoring the register values for process B
(B) Changing address translation tables
(C) Swapping out the memory image of process A to the disk
(D) Both (B) and (C)

5. For each thread in a multithreaded process, there is a separate
(A) Process control block
(B) User address space
(C) User and kernel stack
(D) Kernel space only

6. When a supervisor call is received
(A) Mode switch happens
(B) Process switch happens
(C) Both (A) and (B)
(D) Neither (A) nor (B)

7. What is the purpose of jacketing?
(A) Convert non-blocking system call to blocking system call
(B) Convert blocking system call to non-blocking system call
(C) Convert blocking system call into a new thread
(D) Convert non-blocking system call into a new thread

8. Which of the following statements is/are always true?
(i) Time taken for mode switch is always greater than process switch.
(ii) Time taken for mode switch is always less than process switch.
(iii) Time taken for mode switch is always equal to process switch.
(A) (i) and (iii) (B) (ii) and (iii)
(C) Only (i) (D) Only (ii)

9. Which of the following is the property of time sharing systems?
(i) Multiple user access
(ii) Multiprogramming
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

10. Which of the following is/are not a valid reason for process creation?
(i) Created by OS
(ii) Interactive logon
(iii) Privileged instruction
(A) (i), (ii) (B) (ii), (iii)
(C) (i), (iii) (D) (iii) only

11. Which of the following is/are reason(s) for blocking a running process?
(i) A call from the running program to a procedure that is a part of OS code.
(ii) A running process may initiate an I/O operation.
(iii) A user may block a running process.
(A) (i), (ii) only (B) (ii), (iii)only
(C) (i), (iii) only (D) (iii) only

12. If the OS is pre-empting a running process because a higher priority process on blocked/suspend queue has just become unblocked, then the running process moved to ______ queue.
(A) Suspend (B) Ready/suspend
(C) Blocked (D) Blocked/suspend

13. Which of the following is used to call an OS function?
(A) Interrupt (B) Trap
(C) Supervisor call (D) All of these

14. Which of the following is a general component of a thread?
(i) Thread ID
(ii) Register set
(iii) User stack
(iv) Kernel stack
(A) (i), (iii), (iv) (B) (i), (ii), (iv)
(C) (i), (ii), (iii) (D) (i), (ii), (iii), (iv)

Previous Years' Questions

1. Consider the following statements with respect to User-level threads and Kernel-supported threads. **[2004]**

(1) Context switch is faster with Kernel-supported threads

(2) For user-level threads, a system call can block the entire process

(3) Kernel supported threads can be scheduled independently

(4) User level threads are transparent to the Kernel

Which of the above statements are true?

(A) 2, 3 and 4 only (B) 2 and 3 only

(C) 1 and 3 only (D) 1 and 2 only

2. Which one of the following is true for a CPU having a single interrupt request line and a single interrupt grant line? **[2005]**

(A) Neither vectored interrupt nor multiple interrupting devices are possible

(B) Vectored interrupts are not possible but multiple interrupting devices are possible

(C) Vectored interrupts and multiple interrupting devices are both possible

(D) Vectored interrupt is possible but multiple interrupting devices are not possible

3. Normally user programs are prevented from handling I/O directly by I/O instructions in them. For CPUs having explicit I/O instructions, such I/O protection is ensured by having the I/O instructions privileged. In a CPU with memory mapped I/O, there is no explicit I/O instruction. Which one of the following is true for a CPU with memory mapped I/O? **[2005]**

(A) I/O protection is ensured by operating system routine(s)

(B) I/O protection is ensured by a hardware trap

(C) I/O protection is ensured during system configuration

(D) I/O protection is not possible

4. Consider the following code fragment: if (fork ()==0) **[2005]**

```
{ a = a + 5; printf("%d,%d\n",a,&a);}
else{a=a-5;printf("%d,%d\n",a,&a);}
```

Let u, v be the values printed by the parent process, and x, y be the values printed by the child process. Which one of the following is *true*?

(A) $u = x + 10$ and $v = y$

(B) $u = x + 10$ and $v \neq y$

(C) $u + 10 = x$ and $v = y$

(D) $u + 10 = x$ and $v \neq y$

5. Consider the following statements about user-level threads and Kernel-level threads. Which one of the following statements is *false*? **[2007]**

(A) Context switch time is longer for Kernel-level threads than for user level threads.

(B) User level threads do not need any hardware support.

(C) Related Kernel-level threads can be scheduled on different processors in a multi-processor system.

(D) Blocking one Kernel-level thread blocks all related threads.

6. Which of the following statements about synchronous and asynchronous I/O is NOT *true*? **[2008]**

(A) An ISR is invoked on completion of I/O in synchronous I/O but not in asynchronous I/O

(B) In both synchronous and asynchronous I/O, an ISR (Interrupt Service Routine) is invoked after completion of the I/O

(C) A process making a synchronous I/O call waits until I/O is complete, but a process making an asynchronous I/O call does not wait for completion of the I/O

(D) In the case of synchronous I/O, the process waiting for the completion of I/O is woken up by the ISR that is invoked after the completion of I/O

7. A process executes the following code

for (i=0; i<n; i++) fork( );

The total number of child processes created is **[2008]**

(A) n (B) $2^n - 1$

(C) 2^n (D) $2^{n+1} - 1$

8. A CPU generally handles an interrupt by executing an interrupt service routine **[2009]**

(A) As soon as an interrupt is raised.

(B) By checking the interrupt register at the end of fetch cycle.

(C) By checking the interrupt register after finishing the execution of the current instruction.

(D) By checking the interrupt register at fixed time intervals.

9. A thread is usually defined as 'light weight process' because an operating system (OS) maintains smaller data structures for a thread than for a process. In relation to this, which of the following is true? **[2011]**

(A) On per-thread basis, the OS maintains only CPU register state

(B) The OS does not maintain a separate stack for each thread

(C) On per thread basis, the OS does not maintain virtual memory state.

(D) On per thread basis, the OS maintains only scheduling and accounting information.

10. Let the time taken to switch between user and kernel modes of execution be t_1 while the time taken to switch between two processes be t_2. Which of the following is *true*? **[2011]**

(A) $t_1 > t_2$
(B) $t_1 = t_2$
(C) $t_1 < t_2$
(D) Nothing can be said about the relation between t_1 and t_2

11. A process executes the code

```
fork();
fork();
fork();
```

The total number of **child** processes created is **[2012]**

(A) 3 (B) 4
(C) 7 (D) 8

12. Which one of the following is **FALSE**? **[2014]**

(A) User level threads are not scheduled by the Kernel.
(B) When a user level thread is blocked, all other threads of its process are blocked.
(C) Context switching between user level threads is faster than context switching between Kernel-level threads.
(D) Kernel-level threads cannot share the code segment.

13. Threads of a process share **[2017]**

(A) global variables but not heap.
(B) heap but not global variables.
(C) neither global variables nor heap.
(D) both heap and global variables.

14. Which of the following is/are shared by all the threads in a process? **[2017]**

I. Program counter
II. Stack
III. Address space
IV. Registers

(A) I and II only (B) III only
(C) IV only (D) III and IV only

Chapter 2

Interprocess Communication, Concurrency and Synchronization

LEARNING OBJECTIVES

- *Principles of concurrency*
- *Process interaction*
- *Mutual exclusion*
- *Semaphores*
- *Binary semaphore*
- *Mutual exclusion using semaphores*
- *Progress using semaphores*
- *Classical problems of synchronization*
- *Dining philosophers problem*
- *Monitors*
- *Message passing*
- *Indirect addressing*
- *Mutual exclusion using message passing*

Basic Concepts

Multiprogramming: It deals with the management of multiple processes within a uniprocessor system.

Multiprocessing: It deals with the management of multiple processes within a multiprocessor.

The fundamental operating system (OS) design is *concurrency*. Concurrency encompasses a host of design issues, including communication among processes, sharing of and competing for resources, synchronization of the activities of multiple processes and allocation of processor time to processes.

Principles of Concurrency

There are two examples for concurrent processing as follows:

1. In a single-processor multiprogramming system, processes are interleaved in time to yield the appearance of simultaneous execution.
2. In a multiprocessor system, it is possible not only to interleave the execution of multiple processes but also to overlap them.

There are two problems with these techniques:

1. Problem with sharing of global resources
2. Problem with allocation of resources optimally.
3. Problem with locating a programming error as results is not deterministic and reproducible.

Example:

```
void process( )
{
in = getchar( );
out = in;
putchar(out);
}
```

The procedure 'process' reads a character and prints it. Let us suppose that we have a uniprocessor system, with single user. Let the user running multiple applications and all applications use the procedure for reading and printing, that is, all the applications share common procedure for efficient and close interaction among them. But this sharing leads to problems. For example,

1. Let the process P_1 invokes 'process' and is interrupted immediately after 'getchar' returns its value and stores it in 'in'. Here the most recently entered character '*C*' is stored in variable 'in'.
2. Now, suppose the process P_2 is activated and it invokes 'process', which runs to conclusion, inputting and then displaying a single character, *D*, on the screen.
3. The process P_1 is resumed. By this time, the value '*C*' has been overwritten in 'in' and therefore lost. Instead 'in' contains '*D*', which is transferred to 'out' and displayed.

Here the problem is with sharing a global variable. To avoid these types of problems, we impose some rules like, only one process

at a time may enter 'process' and that once in 'process' the procedure must run to completion before it is available for another process.

This problem is also applicable to multiprocessor systems.

Race condition: A race condition occurs when multiple processes or threads read and write data items so that the final result depends on the order of execution of instructions in the multiple processes.

Example: Let P_1 and P_2 be two processes that share global variables a and b, with initial values $a = 0$, $b = 1$. At some point in its execution, P_1 executes $a = a + b$ and P_2 executes $b = a + b$.
If P_1 executes before P_2, then $a = 1$, $b = 2$.
If P_2 executes before P_1, then $b = 1$, $a = 1$.

OS Concerns for Concurrency

1. The OS must be able to keep track of various processes using PCBs.
2. The OS must allocate and deallocate various resources for each active process.
3. The OS must protect the data and physical resources of each process.
4. The functioning of a process and the output it produces must be independent of the speed at which its execution is carried out relative to the speed of other concurrent processes.

Process Interaction (IPC)

Process classification There are two types of processes as follows:

1. Independent/isolated
2. Cooperating

Independent Process: It cannot affect or be affected by the execution of another process.

Cooperating Process: It can affect or be affected by the execution of another process.

We can classify the ways in which processes interact on the basis of the degree to which they are aware of each other's existence. There are three types of process interaction as follows:

1. Process unaware of each other
2. Process indirectly aware of each other
3. Processes directly aware of each other

Competition Among Processes for Resources

1. This situation arises when processes unaware of each other.
2. There is no exchange of information between the competing processes.
3. But the execution of one process may affect the behaviour of competing processes.
4. With competing processes, there will be three control problems as follows:

Need for mutual exclusion

Example: Suppose two or more processes require access to a single non-sharable resource, such as a printer. Then that resource is referred as *critical resource* and the portion of the program that uses it is called *critical section* of the program. In the case of printer, only one process will have the control of printer while it prints an entire file.

Possibility of deadlock

Example: Two processes waiting for each other indefinitely for the release of resources.

Possibility of starvation

Example: One process is denied access to a particular resource which is required for the execution of that process.

Control of competition inevitably involves the OS, because it is the OS that allocates resources.

Cooperation Among Processes by Sharing

This situation arises when the processes are indirectly aware of each other. Processes may use and update the shared data without reference to other processes but know that other processes may have access to same data. So the control mechanism must ensure the integrity of the shared data. Problems with this type of sharing are

1. Mutual exclusion
2. Deadlock
3. Starvation
4. Data coherence

Data coherence

Suppose two items of data p and q are maintained in the relationship $p = q$, that is, any program that updates p and q values must maintain the relationship.

$$\begin{aligned} \text{Let } P_1 : p &= p + 1; \\ q &= q + 1; \\ P_2 : p &= p * 2; \\ q &= q * 2; \end{aligned}$$

Let initially the state is consistent, that is, $p = 2$, $q = 2$

Then the concurrent execution of P_1 and P_2 with mutual exclusion on p, q will be $p = p + 1;$

$$\begin{aligned} q &= q * 2; \\ q &= q + 1 \\ p &= p * 2; \end{aligned}$$

The final values of p and q will be $p = 6$, $q = 5$.

So the consistency is not maintained.

Cooperation Among Processes by Communication

This situation arises when processes are aware of each other directly. All the processes communicate with each other to synchronize or coordinate the various activities. Problems with this communication are as follows:

1. Deadlock
2. Starvation

Basic Definitions

Atomic operations: A sequence of one or more statements that appears to be indivisible, that is, no process will interrupt the operation.

Critical section A section of code within a process that requires access to shared resources and that must not be executed while another process is in a corresponding section of code.

Deadlock A situation in which two or more processes are unable to proceed because each is waiting for one of the others to do something.

Mutual exclusion The requirement that when one process is in a critical section that accesses shared resources, no other process may be in a critical section that accesses any of those shared resources.

Race condition A situation in which multiple threads or processes read and write a shared data item and the final result depends on the relative timing of their execution.

Starvation A situation in which a runnable process is overlooked indefinitely by the scheduler; although it is able to proceed, it is never chosen.

Critical Section

1. A section of code or set of operations, in which process may be changing shared variables, updating a common file or a table etc.
2. For the process that execute concurrently, it should ensure that execution of critical section should be made atomic. Atomic means that either an operation in the critical section should happen in its entirely or not at all.
3. Critical section of a process should not be executed concurrently with the critical section of another process.
4. To avoid Race Condition, we must have the following:

   'if one process is in critical section, other competing process must be excluded to enter their critical sections, that is, a process must enter the critical section in a mutually exclusive way'.

   This is called *problem of mutual exclusion*.

   Region of code that updates or uses shared data to provide a consistent view of objects need to make sure an update is not in progress when reading the data.
5. Need to provide mutual exclusion for a critical section.

Requirements for Critical Section Problem

Mutual exclusion: No two contending processes should be simultaneously executing inside their critical section.

Bounded waiting: No process should have to wait forever to enter its critical section.

Progress: If no process is executing in its critical section and there exists some processes that wish to enter their critical sections, then only those processes that are not executing in the critical section can participate in the decision of which will enter its critical section next and this selection cannot be postponed indefinitely.

No Assumption: No assumption should be made about relative speed and properties of contenting processes.

Mutual Exclusion

1. Only one process at a time can be updating shared objects.
2. Successful use of concurrency among processes requires the ability to define critical sections and enforce mutual exclusion.
3. Mutual exclusion in the use of a shared resource is provided by making its access mutually exclusive among the processes that share the resources.

Any facility that provides mutual exclusion should meet the following requirements:

1. No assumption regarding the relative speed of the process.
2. A process is in its critical section for a finite time only.
3. Only one process allowed in the critical section.
4. Process requesting access to critical section should not wait indefinitely.
5. A process waiting to enter critical section cannot be blocking a process in critical section or any other process.

Mutual exclusion can be satisfied in one of the following ways:

1. ***Software approach:*** This approach leaves the mutual exclusion responsibility with the process that wish to execute concurrently. This approach is prone to high processing overhead and bugs.
2. ***Hardware support:*** Use special-purpose machine instructions. This approach involves less overhead.
3. ***Provide some level of support within the OS or a programming language:*** Such techniques are as follows:
   - Semaphores
   - Monitors
   - Message passing

Hardware support for mutual exclusion: Use one of the following techniques:

1. Interrupt disabling
2. Special machine instructions
   - Compare and swap instructions
   - Exchange instructions

Interrupt Disabling

To provide mutual exclusion, it is sufficient to prevent a process from being interrupted. A process can enforce mutual exclusion in the following way:

```
while(true)
{
/* disable interrupts */;
/* critical section */;
/* enable interrupts */;
/* remainder */;
}
```

Here, the critical section is not interrupted, so mutual exclusion is guaranteed.

Problems with Interrupt Disabling

The efficiency of execution could be noticeably degraded, because the processor is limited in its ability to interleave processes. Interrupt disabling does not work on in a multiprocessor architecture.

Special Machine Instructions

Two of the most commonly used special machine instructions are as follows:

1. Compare and swap
2. Exchange instruction

Compare and swap instructions It is defined as below:

```
int compare_and_swap(int *word, int
testval, int newval)
{
int oldval;
oldval = *word;
if(oldval == testval)
*word = newval;
return oldval;
}
```

- 'Access to a memory location excludes any other access to that same location.' On the basis of this principle, special machine instructions provide mutual exclusion.
- The above compare and swap instructions will check a memory location (*word) against a test value. If current value is test value, it is replaced with new value. Always the old value is returned.
- The below code provides mutual exclusion using compare and swap instructions:

```
/* Mutual Exclusion */
const int n = /* number of processes */
int S;
void P(int i)
{
while (true)
{
while (compare_and_swap(S, 0, 1)==1)
/* do nothing */;
/* critical section */;
S = 0;
/* remainder */;
}
}
void main( )
{
S = 0;
begin (P(1), P(2) .... P(n));
}
```

Here, a shared variable '*S*' is initialized to '0'. The only process that may enter its critical section is one that finds '*S*' equal to 0.

All other processes at enter their critical sections go into a busy waiting mode.

Busy waiting or *spin waiting* is a technique in which a process can do nothing but continue to execute an instruction or set of instructions that tests the appropriate variable to gain entrance.

When a process leaves, its critical section sets '*S*' to 0. Then the one of the waiting process will get access to enter its critical section.

Exchange instructions The exchange instructions can be defined as follows:

```
void exchange (int reg, int mem)
{
int temp;
temp = mem;
mem = reg;
reg = temp;
}
```

Mutual Exclusion Using Exchange Instructions

```
/* Mutual Exclusion */;
int const n = /* number of processes */;
int S;
void P(int i)
{
int ki = 1;
```

```
while (true)
{
do
exchange(ki, S);
while(ki! = 0);
/* critical section */;
S = 0;
/* remainder */;
}
}
void main( )
{
S = 0;
begin (P(1), P(2), ... P(n));
}
```

A shared variable '*S*' is initialized to '0'. Each process uses a local variable *ki* that is initialized to 1. The only process that may enter its critical section is one that finds '*S*' equal to 0. It excludes all other processes from critical section by setting '*S*' to 1. When a process leaves its critical section, it resets '*S*' to 0 allowing another process to its critical section.

Advantages of using machine instruction approach

1. Applicable to any number of processes on either a single processor or multiple processors, sharing the main memory.
2. Simple and easy to verify.
3. Used to support multiple critical sections.

Disadvantages

1. Busy waiting
2. Starvation is possible
3. Deadlock is possible

Other Mechanisms for Mutual Exclusion

Let us discuss OS and programming language mechanisms that are used to provide concurrency.

Semaphores

Semaphore is an integer value used for signalling among processes.

There are two types of semaphores as follows:

1. Binary semaphore
2. Counting (or) general semaphore

Counting or general semaphore

Three operations may be performed on a semaphore all of which are atomic:

- Initialize
- Decrement
- Increment

The working of a counting semaphore with its operations is defined as below:

1. The semaphore may be initialized to a non-negative integer value.
2. The semwait operation decrements the semaphore value. If the value becomes negative, then the process executing the semwait is blocked, otherwise the process continues execution.
3. The semsignal operation increments the semaphore value. If the resulting value is less than or equal to zero, then one of the processes blocked by a semwait operation, if any, is unblocked.

Example: Let the semaphore value $S = 3$.
If the semaphore value is positive, then that value gives the number of processes that can issue a wait and immediately continue to execute.

Let five processes P_1, P_2, P_3, P_4, P_5 are going to execute a critical section code based on the semaphore value $S = 3$.

$S = \boxed{3}$ ← Initially

↓ P_1 sem wait

$S = \boxed{2}$ ≥ 0, P_1 executes

↓ P_2 sem wait

$S = \boxed{1}$ ≥ 0, P_2 executes

↓ P_3 sem wait

$S = \boxed{0}$ ≥ 0, P_3 executes

↓ P_4 sem wait

$S = \boxed{-1}$ $\ngeq 0$, P_4 Blocked

↓ P_5 sem wait

$S = \boxed{-2}$ $\ngeq 0$, P_5 Blocked

Initially, the '*S*' value 3 means that at a time three processes can issue a 'wait' signal and continue execution.

Whenever S becomes 0, the next process which executes 'wait' operation will be blocked.

Here P_4 is blocked as it operates on the semaphore when $S = 0$.

If the semaphore value becomes negative, it specifies the number of processes waiting to be unblocked.

$S = -2$ means two processes are waiting to be unblocked.

Definition of semwait and semsignal operations

```
struct semaphore
{
int semvalue;
Queuetype Queue;
};
void semwait(semaphore S)
```

```
{
S.semvalue--;
if (S.semvalue < 0)
{
/* place the process in S. Queue */;
/* Block this process */;
}
}
void semsignal(semaphore S)
{
S.semvalue++;
if (S.semvalue < = 0)
{
/* remove a process from S. Queue */;
/* Place the process in ready queue */;
}
}
```

Advantages

1. Because the waiting processes will be permitted to enter their Critical Section in a FCFS order, so the requirement of bounded waiting is met.
2. CPU cycles are saved here as waiting process does not perform any busy waiting.

Disadvantages

1. Complex to implement, since it involves implementation of FCFS.
2. Context switching is more, so more overheads are involved.

Binary semaphore It is a semaphore that takes on only the values 0 and 1.

The operations performed on a binary semaphore are as follows:

1. A binary semaphore may be initialized to 0 or 1.
2. The semwaitB operation checks the semaphore value. If the value is 0, then the process executing the semwaitB is blocked. If the value is 1, then the value is changed to 0 and the process continues execution.
3. The semsignalB operation checks to see if any processes are blocked on this semaphore. If so, then a process blocked by a semwaitB operation is unblocked. If no processes are blocked, then the value of the semaphore is set to 1.

Definition of semwaitB and semsignalB

```
struct binary-semaphore
{
enum {zero, one} value;
Queue-type Queue;
};
void semwaitB(binary-semaphore S)
{
if (S.value = = one)
S.value = zero;
else
{
/* Place this process in S.Queue */;
/* Block this process */;
}
}
void semsignalB(binary-semaphore S)
{
if(S.Queue is empty)
S.value = one;
else
{
/* remove a process from S.Queue */;
/* Place process in ready list */;
}
}
```

Advantages

1. The implementation of binary semaphore is extremely simple.

Disadvantages

1. It does not meet the requirement of Bounded waiting.
2. A process, waiting to enter its Critical Section, will perform Busy waiting, thus wasting CPU cycles.

Notes:

1. Binary semaphores have the same expressive power as general semaphores.
2. *MUTEX*: It is similar to binary semaphore. The key difference between the two is that the process that locks the mutex must be the one to unlock it.
3. Both counting semaphores and binary semaphores use a queue to hold processes waiting on the semaphore. The order in which the processes removed from a Queue is FIFO, that is, the process that has been blocked the longest is released from Queue first.
4. A semaphore whose definition includes the order of removal of Blocked processes is referred as a strong semaphore otherwise it is a weak semaphore.
5. Strong semaphores guarantee freedom from starvation.

Mutual Exclusion Using Semaphores

```
const int n = /* number of processes */;
Semaphore S = 1;
void P(int i)
{
while (true)
{
Semwait(S);
/* critical section */;
Semsignal(S);
```

```
/* remainder */;
}
}
void main( )
{
begin (P(1), P(2),... P(n));
}
```

If no process is executing in Critical Section, then the semaphore values is 1. The first process that is executing 'wait' operation will decrement value to 0 and enter its critical section. The process which execute 'wait' operation while a cooperating process is executing in its critical section, will find the semaphore value to 0 and keep looping in the 'while-loop' of 'wait' operation. Spinning of a waiting process in the while-loop, the binary semaphores are also known as spin locks. When the process executing in the CS makes an exit (from CS), it will execute the 'signal' operation and increment the semaphore value to 1.

At a time, only one of the cooperating processes can enter critical section with the condition that the wait operation is executed automatically. Mutual Exclusion is satisfied.

Example: Consider the following figure (Figure 1) which shows the possible sequence of three processes using mutual exclusion with a semaphore, *S*. Processes *P*, *Q*, *R* accesses a shared resource protected by the semaphore *S*.

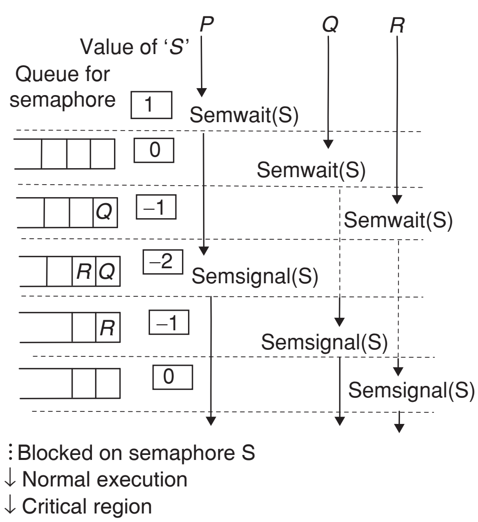

Figure 1 Mutual exclusion using semaphore.

Progress Using Semaphores

When no process is executing in the CS, the semaphore value will be 1. Then, one of the waiting process looping in the while loop of wait-operation will find the semaphore value of 1, exit from the while-loop, decrement the semaphore value to 0 and enter CS. Thus, if no process is executing in critical section and some are waiting to enter, then one of the waiting processes will enter its critical section immediately.

Bounded waiting using semaphores

Actually, one of the waiting processes will get entry into its CS when an operating process executing in its critical section exits. As this selection process is arbitrary, so a process waiting to enter its CS is likely to face starvation. So, the requirement of bounded waiting is not met.

Classical Problems of Synchronization

We will discuss three problems of synchronization:

1. Bounded buffer problem
2. Readers/writers problem
3. Dining philosophers problem

Producer–Consumer Problem

1. Producer inserts item in the buffer
2. Updates Insertion pointer
3. Consumer consumes items in the buffer
4. Updates removal pointer
5. Both update information about how full, how empty the buffer.
6. Prevents buffer overflow, prevents buffer underflow, proper synchronization.

Producer	Consumer
repeat	repeat
produce item *v*;	while (in < = out);
b[in] = *v*;	*w* = *b* [out];
in = in + 1;	out = out + 1;
forever;	consume *w*;
	forever;

Table 1 *Producer consumer problem solution using semaphores*

Producer	Consumer
repeat	repeat
produce item *v*;	while (in < = out);
SemwaitB(*S*);	SemsignalB(*S*);
b[in] = *v*;	*w* = *b*[out];
in = in + 1;	out = out + 1;
SemsignalB(S);	SemsignalB(S);
forever;	consume *w*;
	forever;

If producer is slow or late, then consumer will busy at the while statement.

Table 2 *Improved solution*

Producer	Consumer
repeat	repeat
produce item *v*;	Semwait(n);
Semwait(S);	Semwait(S);
b[in] = *v*;	*w* = *b*[out];
in = in + 1;	out = out + 1;
Semsignal(S);	Semsignal(S);
Semsignal(n);	consume *w*;
forever;	forever;

The initial value of n and S are $n = 0$, $S = 1$. (n is the number of items in the buffer).

Table 3 *Producer consumer bounded buffer problem*

Producer	Consumer
repeat	repeat
produce item v;	while(in == out)
while((in + 1) % n = = out)	no operation;
no operation;	$w = b$[out];
b[in] = v;	out = (out + 1) % n;
in = (in + 1) % n;	consume w;
forever;	forever;

The buffer size is enforced using another counting semaphore.

Table 4 *Producer consumer bounded buffer problem solution*

Producer	Consumers
Repeat	repeat
Produce item v;	Semwait(e);
Semwait(e);	Semwait(S);
Semwait(S);	$w = b$[out];
b[in] = v;	out = (out + 1) % n;
in = (in + 1) % n	Semsignal(S);
Semsignal(S);	Semsignal(e);
Semsignal(e);	consume w;
forever;	forever;

The initial value of buffer size, e is the size of the bounded buffer.

Observations on semaphores:

1. Semaphores are easy to use.
2. wait() and signal() are to be implemented as atomic operations.

Problems:

1. signal() and wait() may be exchanged by the programmer, this may result in deadlock or violation of mutual exclusion.

Readers/Writers Problem

1. A reader reads data.
2. A writer writes data.
3. Data is shared among a number of processes.
4. Multiple readers may read the data simultaneously, that is, concurrently.
5. Only one writer can write the data any time, that is, no reader should be present.
6. A reader and writer cannot access data simultaneously.
7. Locking table: Whether any two can be in the critical section simultaneously is shown in the table.

	Reader	Writer
Reader	OK	NO
Writer	NO	NO

Solution: Readers have priority; if a reader is in CS, any number of readers could enter irrespective of any writer waiting to enter critical section

Writer	Reader
`while(true)`	`while(true)`
`{`	`{`
`Semwait(S);`	`Semwait(x);`
`writeunit();`	`Num = Num + 1;`
`Semsignal(S);`	`if (Num = = 1)`
`}`	`Semwait(S);`
	`Semsignal(x);`
	`Readunit();`
	`Semwait(x);`
	`Num = Num - 1;`
	`if(Num == 0)`
	`Semsignal(S);`
	`Semsignal(x);`
	`}`

Semaphore 'S' is used to enforce mutual exclusion.

Semaphore 'x' is used to assure that 'Num' is updated properly.

Solution: If a writer wants critical section as soon as the critical section is available, writer enters it.

Dining Philosophers Problem

N philosophers are sitting around a dining table. There are N plates placed on the table such that each plate is in front of a philosopher and N forks placed between the plates. There is a bowl of Noodles placed at the centre of the table. Whenever a philosopher feels hungry, he tries to pick two forks which are shared with his nearest neighbour. If any of his neighbours happens to be eating at the time, the philosopher has to wait. Whenever a hungry philosopher gets two forks, he pours noodles into his plate. After he finishes, he places the chopsticks back onto the table and starts thinking. Now forks are available for neighbours.

Solution:

```
# define N 5 /* Number of philosophers*/
void philosopher(int i) /* philosopher number,
from 0 to 4*/
{
while (true)
{
think(); /* philosopher is thinking*/
take_fork(i) ; /*take left fork*/
take_fork ((i+ 1)% N); /* take right fork; %
is modulo operator*/
eat( );
put _ fork ( ); /* put left back on the table*/
put _ fork ((i + 1) % N); /* put right fork
back on the table */
```

Notes:

1. This solution leads to deadlock.
2. Everyone picks the left fork and indefinitely wait for right fork causing starvation.

Monitors

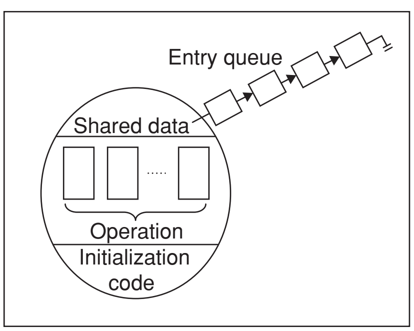
Monitor is a programming language construct that encapsulates variables, access procedures and initialization code within an abstract data type. The monitor's variable may only be accessed via its access procedures and only one process may be actively accessing the monitor at any one time. The access procedures are critical sections. A monitor may have a queue of processes that are waiting to access it.

1. If the data in a monitor represent some resource, then the monitor provides a mutual exclusion facility for accessing the resource.
2. A monitor supports synchronization by the use of condition variables that are contained within the monitor and accessible only within the monitor.
3. Operations on conditional variables:
   - cwait(c): Suspend execution of calling process on condition *c*. The monitor is now available for use by another process.
   - csignal(c): Resume execution of some process blocked after a wait on the same condition. If there are several such processes, choose one of them; if there is no such process, do nothing.

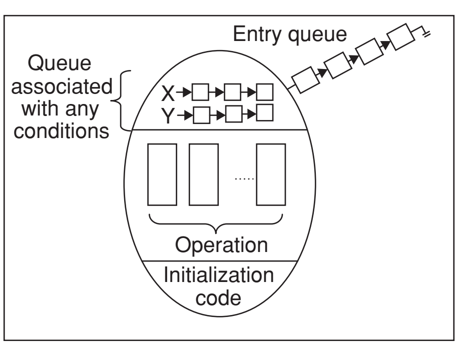
Monitor syntax is as follows:
Monitor monitor - name

```
{
shared variable declarations;
Procedure body P1 (...) {  }
Procedure body P2 (...) {  }
Procedure body Pn (...) {  }
initialization code {  }
}
```

Schematic view of a monitor:



Schematic View of a monitor with condition variables:



Message Passing

When processes interact with one another, two fundamental requirements must be satisfied:

1. Synchronization
2. Communication

One approach to provide both of these is *message passing*.

The primitive functions in message passing are send (destination, message) receive (source, message)

Design Characteristics of Message Systems for IPC and Synchronization

Synchronization There must be some synchronization existing between two processes to communicate with each other.

- ***Send:*** When a 'send' primitive is executed in a process, then the sender may
  - blocked or
  - non-blocked
  - until the message is received.
- ***Receive:*** When a process issues a 'Receive' primitive there are two possibilities:
  1. If a message has previously been sent, the message is received and execution continues.
  2. It there is no waiting message then either
     (i) The process is blocked until a message arrives or
     (ii) The process continues to execute, abandoning the attempt to receive.

Thus, both the sender and receiver may be in one of

1. Blocking send, blocking receive: Allows tight synchronization.
2. Non-blocking send, blocking receive:
   - Useful synchronization
   - Possibility of generating repeated messages
3. Non-blocking send, non-blocking receive: No need to wait

Addressing Two types of addressing methods:

1. Direct addressing
2. Indirect addressing

Direct Addressing

The send primitive includes a specific identifier of the destination process. The 'receive' primitive can be handled in one of two ways:

Explicit

The process must know ahead of time from which process a message is expected. Useful for cooperating concurrent processes.

Implicit

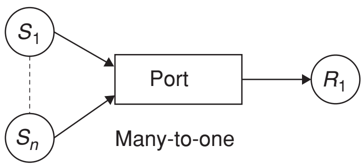
The 'source' parameter of 'receive' primitive possesses a value returned when the receive operation has been performed. Example, Printer server.

Indirect Addressing

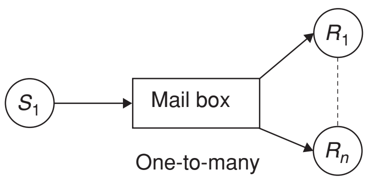
Messages are not sent directly from sender to receiver but rather are sent to a shared data structure consisting of queues that can temporarily hold messages. These queues are referred to as mailboxes The relationship between the sender and receiver is

- one-to-one
- one-to-many
- many-to-one
- many-to-many

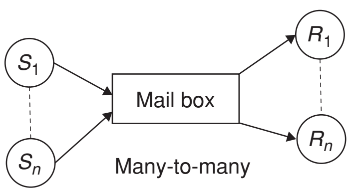
One-to-one



Many-to-one

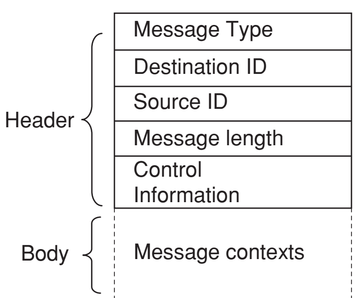


One-to-many



Many-to-many

Message format The general message format will be



Queuing discipline The queuing discipline may be

- FIFO
- Priority

Mutual Exclusion using message passing:

```
const int n = /* number of processes */;
void P(int i)
{
message msg;
while (true)
{
receive (box, msg);
/* critical section */;
send (box, msg);
/* remainder */;
}
}
void main( )
{
create mailbox(box);
send(box, null);
begin (P(1), P(2) ... P(n));
}
```

1. Here a set of concurrent processes that share a mailbox ‘box’, which can be used by all processes to send and receive.
2. The mailbox is initialized to contain a single message with null content. A process wishing to enter its critical section first attempts to receive a message.
3. If the mail box is empty, then the process is blocked.
4. Once a process acquired the message, it performs its critical section and then places the message back into the mailbox.
5. Hence, the message functions as a token that is passed from process to process.

Exercises

Practice Problems I

Directions for questions 1 to 17: Select the correct alternative from the given choices.

1. The value of a counting semaphore is 7. Then 15 wait operations and 10 signal operations were completed on this semaphore. The resulting value of semaphore is
(A) 5 (B) 7
(C) 2 (D) 0

2. At a particular time of computation, the value of counting semaphore is 7. Then 20 wait operations and ‘x’ signal operations were completed on this semaphore. If the final value of the semaphore is 5, what is x?
(A) 18 (B) 13
(C) 5 (D) 0

3. A process using a semaphore has a start value of 1 for its semaphore. Since the start of execution of the program, 12 signal operations were completed. How many wait operations have been completed so far if the current value of semaphore is 6?
(A) 1 (B) 5
(C) 7 (D) 11

4. It is found that a program has multiple critical sections. Choose correct statements from below:
(i) Multiple semaphores are needed for handling the situation.
(ii) A single semaphore that uncompresses all the critical section is sufficient and is also more efficient.
(iii) To get better control of the code, monitors need to be implemented.
(A) (i) and (ii) (B) (ii) and (iii)
(C) (i) and (iii) (D) (i), (ii), (iii)

5. Consider the below psuedocode:

```
semaphore S = 1;
semaphore E = 1;
if(thread_count++ <100)
spawnnewthread( );
wait(E);
 // critical section - begin
 ---------------
 ---------------
 // critical section - end
 signal(S);
```

Assume that above pseudocode gets called a hundred times, what is the count of semaphore E?
(A) 0 (B) 1
(C) –99 (D) –100

6. Consider the below code for a process i:

```
-------------
-------------
flag[i] = true;
if(turn == i and flag [i] == true)
/* critical section begin */
counter++;
/* critical section end */
turn = x;
-------------
-------------
```

If the value of a counter started, what would be the value of 'counter' count at the end of the program:
(A) Semaphore count
(B) Thread count
(C) Concurrency count
(D) Deadlock process count

7. Consider the below pseudocode:

```
function waitB(s)
{
if(s.value ==1)
s.value = 0;
else
place the process in the Queue;
}
function signalB(s)
{
s. value = 1;
}
```

What does the code most likely behave as
(A) general semaphore (B) weak semaphore
(C) binary semaphore (D) mutex

8. A shared variable x, initialized to 0 is operated on by four concurrent processes P, Q, R, S as follows:

```
P(x)                     Q(x)
{                        {
wait( );                 wait( );
read(x);                 read(x);
increment x by 1;        increment x by 1;
store(x);                store(x);
signal();                signal( );
}                        }
R(x)                     S(x)
{                        {
wait( );                 wait( );
read (x);                read(x);
decrement x by 2;        decrement x by 2;
store (x);               store(x);
signal( );               signal( );
}                        }
```

A counting semaphore 'N' is used by the processes whose value is initialized to 2. What is the maximum possible value of 'x' after all processes complete execution?
(A) –2 (B) –1
(C) 1 (D) 2

9. Consider the following code:

```
Program concurrency;
Var x: Integer (: = 0);
     y: Integer (: = 0);
Procedure threadA( ) ;
begin
x = 1; /*S1*/
y = y + x; /*S2*/
end;
Procedure threadB( ) ;
begin
y = 4;      /*S3*/
x = x + 5;  /*S4*/
end;
begin /*mainprogram*/
parbegin
threadA( );
threadB( );
parend;
    end.
```

Suppose a process has two concurrent threads: one thread executes statements S_1 and S_2, and the other thread executes statements S_3 and S_4. What are the maximum possible values of x and y when the code finishes execution? (All the statements S_1, S_2, S_3 and S_4 are atomic).

(A) $x = 6, y = 4$ (B) $x = 6, y = 5$
(C) $x = 1, y = 5$ (D) $x = 6, y = 10$

10. Consider the following program:

```
boolean lock[2];
int turn;
void P(int id)

{
while(true)
{
lock[id] = true;
while (turn! = id)
{
while (lock [1 - id])
/*do nothing*/
turn = id;
}
/*critical section*/
lock[id] = false;
/*reamainder*/
  }
}
void main( )
{
lock[0] = false;
lock[1] = false;
turn = 0;
parbegin (P(0), P(1));
}
```

Which of the following statements is correct for two processes executing this code?

(A) Given program provides mutual exclusion.
(B) Given program does not provide mutual exclusion.
(C) Given program provides mutual exclusion and also solves starvation problem.
(D) Given program provides mutual exclusion but does not prevent from starvation.

11. Consider two process P_0 and P_1 which share the following variables:

```
boolean flag [2]; /*initially false*/
int turn;
```

These two processes, $Pi(i = 0$ or $1)$, Pj $(j = 1$ or $0)$ execute the following code:

```
do
{
flag[i] = TRUE;
while(flag [j])
{
if (turn = = j)
{
flag[i] = false;
while (turn = = j);
flag [i] = TRUE;
}
}
// critical section
turn = j;
flag[i] = FALSE;
// remainder.
}
```

while(TRUE);

The code satisfies

(i) Mutual exclusion
(ii) Progress
(iii) Bounded waiting

(A) (i), (ii) only (B) (ii), (iii) only
(C) (i), (iii) only (D) (i), (ii), (iii)

12. Which of the following statement(s) is false?

(i) Spinlocks are not appropriate for single-processor systems.
(ii) Mailboxes may be used for synchronization.
(iii) Message passing and semaphores do not have equivalent functionality.

(A) (i) only (B) (iii) only
(C) (i), (iii) (D) (i), (ii), (iii)

13. Consider the following code:

```
signal (mutex);
............ .
Critical section
............ .
wait (mutex);
```

Here 'mutex' is a semaphore variable, which is initialized to 1. Then

(A) Mutual exclusion is provided
(B) Mutual exclusion violated, if several processes are simultaneously active in their critical section.
(C) Deadlock will occur
(D) Starvation is possible

14. Which of the following sequence of 'wait' and 'signal' operations leads to deadlock?
(Here 'mutex' is a semaphore variable initialized to 1.)

(A)
```
wait (mutex);
.........
Critical section
......... .
Signal (mutex);
```

(B)
```
wait (mutex);
………..
Critical section
……………
Wait (mutex);
```
(C)
```
Signal (mutex);
…………
Critical section
……….
Wait (mutex);
```
(D)
```
signal (mutex);
…………
Critical section
………….
Signal (mutex);
```

15. Which of the following situation arises if a process omits the wait(S) or the signal(S) on a semaphore variable '*S*' (Initially *S* = 1).
(i) Mutual exclusion violated
(ii) Deadlock will occur
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

16. consider the following shared data and code:
```
data:
int turn;
Boolean flag[2];
Code:
do
{
flag [i] = TRUE;
turn = j;
while (flag [j] && turn = = j);
//critical section
flag [i] = FALSE;
//remainder
}
while (TRUE);
```
Let two processes *Pi* (*i* = 0 or 1) and *Pj* (*j* = 1 or 0) use the shared data and executes the code. Then the code provides
(A) a solution to critical section problem
(B) mutual exclusion but not progress.
(C) progress but not mutual exclusion
(D) both mutual exclusion, progress but no bounded waiting.

17. Consider the following code that shows the structure of a process in an algorithm to solve the critical section problem for two processes.
var flag[2] of Boolean; /* initialized to false */
repeat
flag[*i*] = true;
while flag[*j*] do no – op;
//critical section
flag[*i*] = false;
// remainder
until false
Then which of the following statements is true?
(A) The algorithm satisfies all the requirements of critical section problem.
(B) The algorithm satisfies only mutual exclusion and progress.
(C) The algorithm only satisfies progress requirement.
(D) The algorithm does not satisfy critical section problem requirements.

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. The result of a computation depends upon the speed of the processes involved, is said to be:
(A) Cycle stealing (B) Race condition
(C) A time lock (D) A deadlock

2. A relation between processes such that each has some part which must not be executed, while the critical section of another is being executed is known as
(A) Mutual exclusion (B) Semaphore
(C) Multi-tasking D) Mutli-programming

3. Producer–consumer problem can be solved using
(A) Semaphores (B) Event counters
(C) Monitors (D) All of the above

4. To avoid the race condition, the number of processes allowed in critical section is
(A) 0 (B) 1
(C) 2 (D) 3

5. Mutual exclusion problem occurs between
(A) Two disjoint processes that unaware of each other
(B) Processes that share resources
(C) Processes directly aware of each other.
(D) Both (A) and (B)

6. Semaphores are used to solve the problem of
(A) Race condition (B) Multitasking
(C) Mutual exclusion (D) Both (A) and (C)

7. At a particular time, the value of a counting semaphore is 10. It will become 7 after
(A) 3 signal operations
(B) 3 wait operations
(C) 5 signal operations and 2 wait operations
(D) None of the above

8. Critical region is
(A) A part of the OS which is not allowed to be accessed by any process
(B) A set of instructions that accesses common shared resource, which exclude one another in time

(C) The portion of main memory, which can be accessed only by one process at a time
(D) Both (A) and (C)

9. Concurrent processes are:
(A) Processes that don't overlap in time
(B) Processes that overlap in time
(C) Processes that are executed
(D) Processes that are executed by a processor at the same time

10. Semaphore operations are atomic because they are implemented within the_______.
(A) Kernel (B) Shell
(C) User process (D) Normal process space

11. The programming language construct that provides equivalent functionality of a semaphore and better control is
(A) Signal (B) Monitor
(C) Mutex (D) Critical section.

12. What is the ideal way of emptying the queue of a strong semaphore?
(A) Random (B) LIFO
(C) FIFO (D) binary

13. What are the disadvantages of machine instruction approach?
(i) While a process is waiting for entering a critical section, process still consumes resources.
(ii) There could be starvation
(iii) There could be deadlocks
(A) (i), (ii) only (B) (ii), (iii) only
(C) (iii), (i) only (D) (i), (ii), (iii)

14. Select from below the advantages of Machine Instruction approach?
(i) Applicable to any number of processes either uniprocessor or multi-processor system
(ii) Simple and easy to verify
(iii) Supports multiple critical sections
(A) (i), (ii) only (B) (ii), (iii) only
(C) (iii), (i) only (D) (i), (ii), (iii)

15. Which of the below are requirements for mutual exclusion?
(i) Only one process is allowed into critical section.
(ii) A process remains inside its critical section for finite time only.
(iii) It must be possible for a process accessing critical section to be delayed indefinitely.
(iv) A process halting in critical section must do so without interfering with other processes.
(A) (i), (ii), (iii) (B) (ii), (i), (iv)
(C) (i), (ii), (iv) (D) (i), (ii), (iii), (iv)

Previous Years' Questions

1. Consider these two functions and two statements S_1 and S_2 about them: **[2006]**

`int work1 (int *a,int i, int j)` `{` `int x=a[i+2];` `a[j]=x+1;` `return a[i+2]-3;` `}`	`int work2 (int *a,int i, int j)` `{` `int t1=i+2;` `int t2=a[t1];` `a[j]=t2+1;` `return t2 - 3;` `}`

S1: The transformation from work1 to work2 is valid, that is,for any program state and input arguments, work 2 will compute the same output and have the same effect on program state as work 1
S2: All the transformations applied to work 1 to get work 2 will always improve the performance (i.e., reduce CPU time) of work 2 compared to work 1
(A) S_1 is false and S_2 is false
(B) S_1 is false and S_2 is true
(C) S_1 is true and S_2 is false
(D) S_1 is true and S_2 is true

2. The atomic fetch-and-set x, y instructions unconditionally sets the memory location x to 1 and fetches the old value of the of x in y without allowing any intervening access to the memory location x. Consider the following implementation of P and V functions on binary semaphore S.

```
void P (binary-semaphore *s) {
    unsigned y;
    unsigned *x = & (s → value);
    do {
          fetch-and-set x, y ;
          } while (y) ;
    }
void V (binary-semaphore *s) {
s → value = 0;
}
Which one of the following is true?
```
[2006]

(A) The implementation may not work if context switching is disabled in P
(B) Instead of using fetch-and-set, a pair of normal load/store can be used
(C) The implementation of V is wrong
(D) The code does not implement a binary semaphore

3. The P and V operations on counting semaphores, where s is a counting semaphore, are defined as follows:

$P(s)$: $s = s - 1$;
  if $s < 0$ then wait;
$V(s)$: $s = s + 1$;
if $s <= 0$ then wake up a process waiting on s;

Assume that P_b and V_b, the wait and signal operations on binary semaphores, are provided. Two binary semaphores x_b and y_b are used to implement the semaphore operations $P(s)$ and $V(s)$ as follows:

```
P(s) :        Pb (xb) ;
    s = s - 1;
    if (s < 0) {
       Vb (xb) ;
       Pb (yb) ;
    }
    else Vb (xb) ;
V(s) :        Pb (xb) ;
    s = s + 1;
    if (s<=0) Vb (yb) ;
       Vb (xb) ;
```

The initial values of x_b and y_b are respectively **[2008]**

(A) 0 and 0 (B) 0 and 1
(C) 1 and 0 (D) 1 and 1

4. Consider a system with four types of resources R_1 (3 units), R_2 (2 units), R_3 (3 units), R_4 (2 units). A non-pre-emptive resource allocation policy is used. At any given instance, a request is not entertained if it cannot be completely satisfied. Three processes P_1, P_2, P_3 request the resources as follows if executed independently. **[2009]**

Process P_1:	**Process P_2:**	**Process P_3:**
$t = 0$: requests 2 units of R_2	$t = 0$: requests 2 units of R_3	$t = 0$: requests 1 unit of R_4
$t = 1$: requests 1 unit of R_3	$t = 2$: requests 1 unit of R_4	$t = 2$: requests 2 units of R_1
$t = 3$: requests 2 units of R_1	$t = 4$: requests 1 unit of R_1	$t = 5$: releases 2 units of R_1
$t = 5$: releases 1 unit of R_2 and 1 unit of R_1.	$t = 6$: releases 1 unit of R_3	$t = 7$: requests 1 unit of R_2
$t = 7$: releases 1 unit of R_3	$t = 8$: Finishes	$t = 8$: requests 1 unit of R_3
$t = 8$: requests 2 units of R_4		$t = 9$: Finishes
$t = 10$: Finishes		

Which one of the following statements is true if all three processes run concurrently starting at time $t = 0$?

(A) All processes will finish without any deadlock
(B) Only P_1 and P_2 will be in deadlock.
(C) Only P_1 and P_3 will be in a deadlock.
(D) All three processes will be in deadlock.

5. The enter_CS() and leave_CS() functions to implement critical section of a process are realized using test-and-set instruction as follows: **[2009]**

```
void enter_CS(X)
{
    while (test-and-set(X)) ;
}
void (leave_CS(X))
{
    X=0;
}
```

In the above solution, X is a memory location associated with the CS and is initialized to 0. Now consider the following statements:

(i) The above solution to CS problem is deadlock-free.
(ii) The solution is starvation free.
(iii) The processes enter CS in FIFO order.
(iv) More than one process can enter CS at the same time.

Which of the above statements is true?

(A) (i) only
(B) (i) and (ii)
(C) (ii) and (iii)
(D) (iv) only

6. Consider the methods used by processes P_1 and P_2 for accessing their critical sections whenever needed, as given below. The initial values of shared Boolean variables S_1 and S_2 are randomly assigned. **[2010]**

Method used by P_1	**Method used by P_2**
while ($S_1 == S_2$);	while ($S_1 != S_2$);
Critical section	Critical section
$S_1 = S_2$;	$S_2 = \text{not}(S_1)$;

Which one of the following statements describes the properties achieved?

(A) Mutual exclusion but not progress
(B) Progress but not mutual exclusion
(C) Neither mutual exclusion nor progress
(D) Both mutual exclusion and progress

7. The following program consists of three concurrent processes and three binary semaphores. The semaphores are initialized as $S_0 = 1$, $S_1 = 0$, $S_2 = 0$.

Process P_0	**Process P_1**	**Process P_2**
`while (true) {`	`wait (S1);`	`wait (S2);`
`wait (S0);`	`Release (S0);`	`release (S0);`
`print '0'`		
`release (S1);`		
`release (S2);`		
`}`		

How many times will process P_0 print '0'? **[2010]**

(A) At least twice (B) Exactly twice
(C) Exactly thrice (D) Exactly once

8. Fetch _ And _Add(X, i) is an atomic Read- Modify-Write instruction that reads the value of memory location X, increments it by the value i, and returns the old value of X. It is used in the pseudocode shown below to implement a busy wait lock. L is an unsigned integer shared variable initialized to 0. The value of 0 corresponds to lock being available, while any non-zero value corresponds to the lock being not available. **[2012]**

```
AcquireLock(L) {
while(Fetch_And_Add(L, 1))
L = 1;
}
ReleaseLock (L) {
L = 0;
}
```

This implementation

(A) fails as L can overflow
(B) fails as L can take on a non-zero value when the lock is actually available
(C) works correctly but may starve some processes
(D) works correctly without starvation

9. A shared variable x, initialized to 0, is operated on by four concurrent processes W, X, Y, Z as follows. Each of the processes W and X reads x from memory, increments by one, stores it to memory, and then terminates. Each of the processes Y and Z reads x from memory, decrements by two, stores it to memory, and then terminates. Each process before reading x invokes the P operation (i.e., wait) on a counting semaphore S and invokes the V operation (i.e., signal) on the semaphore S after storing x to memory. Semaphore S is initialized to 2. What is the maximum possible value of x after all processes complete execution? **[2013]**

(A) –2 (B) –1
(C) 1 (D) 2

10. A certain computation generates two arrays 'a' and 'b' such that $a[i] = f(i)$ for $0 \le i < n$ and $b[i] = g(a[i])$ for $0 \le i < n$. Suppose this computation is decomposed into two concurrent processes X and Y such that X computes the array 'a' and Y computes the array 'b'. The processes employ two binary semaphores R and S, both initialized to zero. The array 'a' is shared by the two processes. The structures of the processes are shown below.

Process *X*:

```
private i;
for (i=0; i<n; i++) {
    a[i] = f(i);
    ExitX(R, S);
}
```

Process *Y*:

```
private i;
for (i=0; i<n; i++) {
EntryY(R, S);
    b[i] = g(a[i]);
}
```

Which one of the following represents the correct implementations of Exit$X$ and Entry$Y$? **[2013]**

(A)
```
ExitX(R, S) {
    P(R);
    V(S);
}
    EntryY(R,S){
    P(S);
    V(R);
}
```

(B)
```
ExitX(R, S) {
    V(R);
    V(S);
}
    EntryY(R,S){
    P(R);
    P(S);
}
```

(C)
```
ExitX (R, S){
    P(S);
    V(R);
}
    EntryY(R,S){
    V(S);
    P(R);
}
```

(D)
```
ExitX (R, S){
    V(R);
    P(S);
}
    EntryY(R,S){
    V(S);
    P(R);
}
```

11. Consider the procedure below for the *producer-consumer* problem which uses semaphores; **[2014]**

```
semaphore n = 0;
semaphore s = 1;
void producer ()
{
while (true)
{
produce ( )
semWait (s);
addToBuffer ();
semSignal (s);
semSignal (n);
}
}
void consumer ()
{
while (true)
{
semWait (s);
semWait (n);
remove FromBuffer ();
semSignal(s);
consume ( ) ;
}
}
```

Which one of the following is true?

(A) The producer will be able to add an item to the buffer, but the consumer can never consume it.
(B) The consumer will remove no more than one item from the buffer.
(C) Deadlock occurs if the consumer succeeds in acquiring semaphore s when the buffer is empty.
(D) The starting value for the semaphore n must be 1 and not 0 for deadlock free operation.

12. The following two function $P1$ and $P2$ that share a variable B with an initial value of 2 execute concurrently. **[2015]**

```
P1 ( ) {                     P2 ( )  {
   C = B – 1;                   D = 2 * B;
   B = 2 * C;                   B = D – 1;
}                               }
```

The number of distinct values that B can possibly take after the execution is _______

13. Two processes X and Y need to access a critical section. Consider the following synchronization construct used by both the processes **[2015]**

Process X	**Process Y**

`/* other code for process X */`
`while (true)`
`{`
`varP = true;`
`while(varQ == true)`
`{`
`/* Critical Section */`
`varP = false;`
`}`
`}`
`/* other code for process X */`
	`/* other code for process Y */ while (true)`
	`{`
	`varQ = true;`
	`while (varP == true)`
	`{`
	`/* Critical Section */`
	`varQ = false;`
	`}`
	`}`
	
	`/* other code for process Y */`

Here, var$P$ and var$Q$ are shared variables and both are initialized to false. Which one of the following statements is true?

(A) The proposed solution prevents deadlock but fails to guarantee mutual exclusion.
(B) The proposed solution guarantees mutual exclusion but fails to prevent deadlock.
(C) The proposed solution guarantees mutual exclusion and prevents deadlock.
(D) The proposed solution fails to prevent deadlock and fails to guarantee mutual exclusion.

14. Consider the following proposed solution for the critical section problem. There are n process: $P_0 \ldots P_{n-1}$. In the code, function pmax returns an integer not smaller than any of its arguments. For all i, $t[\,i\,]$ is initialized to zero. **[2016]**

do {
$c[\,i\,] = 1$; $t\,[\,i\,] = \text{pmax}\,(t[\,i\,], \ldots\ldots,$
$t[n-1]) + 1$; $c[\,i\,] = 0$;
for every $j \neq i$ in $(0, \ldots., n-1)$ {
while ($c\,[\,j\,]$);
while ($t[\,j\,]\,! = 0$ && $t[\,j\,] < = t[\,i\,]$);
}
Critical Section;
$t[\,i\,] = 0$;
Remainder Section;
} while (true);

Which one of the following is TRUE about the above solution?

(A) At most one process can be in the critical section at any time.
(B) The bounded wait condition is satisfied.
(C) The progress condition is satisfied.
(D) It cannot cause a deadlock.

15. Consider the following two - process synchronization Solution.

Process 0	Process 1
Entry: loop while (turn = = 1);	Entry: loop while (turn = = 0);
(Critical section)	(Critical section)
Exit: turn = 1;	Exist: turn = 0;

The shared variable *turn* is initialized to zero. Which one of the following is **TRUE**? **[2016]**

(A) This is a correct two - process synchronization Solution.
(B) This Solution violates mutual exclusion requirement.
(C) This Solution violates progress requirement.
(D) This Solution violates bounded wait requirement.

16. Consider a non-negative counting semaphore S. The operation $P(S)$ decrements S, and $V(S)$ increments S. During an execution, 20 $P(S)$ operations and 12 $V(S)$ operations are issued in some order. The largest initial value of S for which at least one $P(S)$ operation will remain blocked is _____ . **[2016]**

17. A multithreaded program P executes with x number of threads and uses y number of locks for ensuring mutual exclusion while operating on shared memory locations. All locks in the program are *non-reentrant*, i.e., if a thread holds a lock l, then it cannot re-acquire lock l without releasing it. If a thread is unable to acquire a lock, it blocks until the lock becomes available. The *minimum* value of x and the *minimum* value of y together for which execution of P can result in a deadlock are: **[2017]**

(A) $x = 1, y = 2$ (B) $x = 2, y = 1$
(C) $x = 2, y = 2$ (D) $x = 1, y = 1$

18. Consider the following solution to the producer-consumer synchronization problem. The shared buffer size is N. Three semaphores empty, full and mutex are defined with respective initial values of 0, N and 1. Semaphore empty denotes the number of available slots in the buffer, for the consumer to read from. Semaphore full denotes the number of available slots in the buffer, for the producer to write to. The placeholder variables, denoted by P, Q, R, and S, in the code below can be assigned either empty or full. The valid semaphore operations are: wait () and signal ().

Producer	Consumer

do {
  wait(P);
  wait (mutex);
  //Add item to
  buffer
  signal (mutex);
  signal (Q);
} while (1);
	do {
	  wait(R);
	  wait (mutex);
	  //Consume item
	  from buffer
	  signal (mutex);
	  signal (S);
	} while (1);

Which one of the following assignments to P, Q, R and S will yield the correct solution? **[2018]**

(A) P: full, Q: full, R: empty, S: empty
(B) P: empty, Q: empty, R: full, S: full
(C) P: full, Q: empty, R: empty, S: full
(D) P: empty, Q: full, R: full, S: empty

Deadlock and CPU Scheduling

LEARNING OBJECTIVES

- *Deadlock*
- *System model*
- *Bridge crossing*
- *Resources*
- *Resource allocation graph*
- *Methods of handling deadlocks*
- *Deadlock prevention*
- *Resource allocation denial (OR) banker's algorithm*
- *Deadlock detection*
- *Dining philosophers problem*
- *Scheduling algorithms*
- *Scheduling policies*
- *Round Robin scheduling*
- *Shortest remaining time*
- *Highest response ratio next*
- *Multilevel feedback queue scheduling*

Deadlock

It is a situation where a process or set of processes is blocked, waiting for some resource that is held by other waiting processes.

System Model

Let the resource types be R_1, R_2 ... R_m (like CPU cycles, memory space, input/output (I/O) devices, etc.). Each resource type R_i has W_i instances; each process utilizes a resource as follows:

Request A process, needing a resource, will request the operating system (OS) for assignment of the needed resource. Then the process waits, till operating system assigns it an instance of the requested resource.

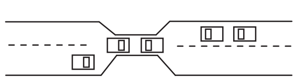
Assignment The OS will assign to the requesting process an instance of the requested resource, whenever, it is available. Then, the process comes out of its waiting state.

Use The process will use the assigned resource. In case, the resource is non-sharable, the process will have exclusive access to it.

Release After the process finished with the use assigned resource, it will return the resource to the system pool. The released resource can now be assigned to another waiting process.

Example:

Bridge crossing



Traffic is allowed only in one direction. Each section of a bridge can be viewed as a resource.

If a deadlock occurs, it can be resolved if one car backs up (preempt resources and rollback). Several cars may have to be backed up if a deadlock occurs.

Problem of starvation (infinite wait) is possible.

Resources

Types of resources:

1. Reusable resources
2. Consumable resources

Reusable resources These resources can be safely used by only one process at a time, and are not depleted by that use.

Examples: Processors, I/O channels, main and secondary memory, devices and files, etc.

Consider two processes P and Q that compete for exclusive access to a disk file D and tape drive T. Let their implementation is as shown below:

Table 1 *Process P*

Step	Action
P_0	Request (D)
P_1	Lock (D)
P_2	Request (T)
P_3	Lock (T)
P_4	Perform function
P_5	Unlock (D)
P_6	Unlock (T)

Table 2 *Process Q*

Step	Action
Q_0	Request (T)
Q_1	Lock (T)
Q_2	Request (D)
Q_3	Lock (D)
Q_4	Perform Function
Q_5	Unlock (T)
Q_6	Unlock (D)

P and Q are executing on a single processor in interleaved fashion. Then deadlock occurs if each process holds one resource and requests the other.

For example, deadlock occurs if the multiprogramming system interleaves the execution of the two processes as follows:

$$P_0, P_1, Q_0, Q_1, P_2, Q_2$$

One strategy to deal with this type of deadlocks is to impose system design constraints concerning the order in which resources can be requested.

Consumable resources A consumable resource is one that can be created and destroyed. There is no limit on the number of consumable resources of a particular type.

Examples: Interrupts, signals, messages, etc.
Consider the following pair of processes, in which each process attempts to receive a message from the other process and then send a message to the other process:

P_1	P_2
. . . .	. . . .
receive (P_2);	receive (P_1);
. . . .	. . . .
send (P_2, M_1);	send (P_1, M_2);

Deadlock occurs in above case, if the receive is blocking. There is no single effective strategy that can deal with all types of deadlocks.

Deadlock Characteristics

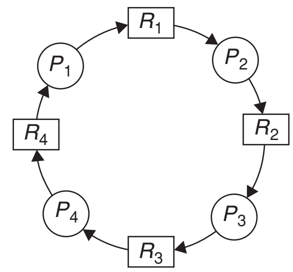
Deadlock is an undesirable state of the system. The following are the four conditions that must hold simultaneously for a deadlock to occur:

Mutual exclusion A resource can be used by only one process at a time. If another process requests for that resource then the requesting process must be delayed until the resource has been released.

Hold-and-wait Some processes must be holding some resources in a non-sharable mode and at the same time must be waiting to acquire some more resources, which are currently held by other processes in a non-sharable mode.

No pre-emption Resources granted to a process can be released back to the system only as a result of the voluntary action of that process, after the process has completed its task.

Circular wait Deadlocked processes are involved in a circular chain such that each process holds one or more resources being requested by the next process in the chain.



Resource Allocation Graph

A deadlock is described in terms of a directed graph called a system Resource Allocation Graph (RAG). It consists of two sets:

1. The set of vertices, V
2. The set of edges, E

The set of vertices is again divided into two categories.

The set of all active processes in the system is $P = \{P_1, P_2, \ldots P_n\}$ and the set of all different type of resources i.e., $R = \{R_1, R_2 \ldots R_m\}$

There are two types of edges in the RAG:

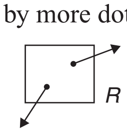
1. A directed edge from the process P_i to resources type R_j and is denoted by $P_i \to R_j$. It signifies that the ith process is requesting one unit of the resource type j. This edge is request edge.
2. A directed edge from the resource R_i to process P_j denoted by $R_i \to P_j$. It signifies that one unit of ith resource is held by the process j. This edge is also called as an *allocation edge/assignment edge*.

Notations Used in RAGs

We denote a process by a circle and each resource by a rectangle.

Process		P_i requests instance of R_j	R_j
Resource Type with four instances		P_i is holding an instance of R_j	R_j

However, if we have more number of instances of a resource type, then it is denoted by more dots.



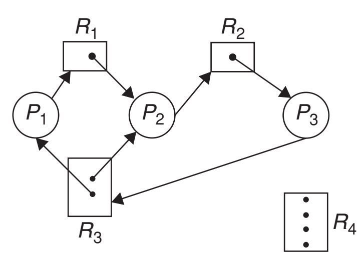


Figure 1 RAG with deadlock.

Notes:

1. If a cycle exists in the RAG, there may or may not be a deadlock.
2. Acyclic RAG implies no deadlock.
3. No deadlock implies acyclic RAG. This means that cycles can be there even if there is no deadlock.

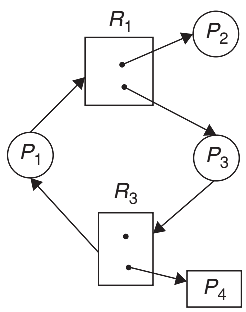

Figure 2 RAG with no deadlock but contains cycle.

Notes:

1. If graph contains no cycles, then no deadlock.
2. If graph contains a cycle

If there is only one instance per resource type, then deadlock occurs.

If there are several instances per resource type, deadlock may occur.

Methods of Handling Deadlocks

There are three approaches to deal with deadlocks. They are

1. Deadlock prevention
2. Deadlock avoidance
3. Deadlock detection

Deadlock Prevention

1. The strategy of deadlock prevention is to design a system in such a way that the possibility of deadlock is excluded.
2. Two classes of deadlock prevention are
   - Indirect method
   - Direct method

Indirect method Prevent the occurrence of one of three necessary conditions of deadlock i.e., mutual exclusion, No pre-emption and hold and wait.

Direct method Prevent the occurrence of circular wait.

Prevention Techniques

Mutual exclusion This is supported by the OS.

Hold and wait

1. This condition can be prevented by requiring that a process request all of its required resources at one time and blocking the process until all requests can be granted simultaneously.
2. But this prevention does not yield good results because
   - Long waiting time required
   - Not efficient use of allocated resources
   - A process may not know all the required resources in advance.

Advantages

1. Works well for processes that perform a single burst of activity.
2. No pre-emption necessary.

No pre-emption Prevention strategies for 'no pre-emption' are

1. If a process that is holding some resources, requests another resource that cannot be immediately allocated to it, then all resources currently being held are released and if necessary request them again together with the additional resources.
2. If a process requests a resource that is currently held by another process, the OS may pre-empt the second process and require it to release its resources. This technique works only when two processes do not have same priority.

Advantages

Convenient when applied to resources whose state can be saved and restored easily.

Disadvantage

Pre-empts more often than necessary.

Circular wait One way to ensure that this condition never holds is to impose a total ordering of all resource types and to require that each process requests resource in an increasing order of enumeration, i.e., if a process has been allocated resources of type R, then it may subsequently request only those resources of types following R in the ordering.

Advantages

1. Feasible to enforce via compile time checks.
2. No run-time computation required.

Disadvantages

1. Disallows incremental resources requests.

Note: The deadlock prevention strategies are conservative and undercommits resources.

Deadlock Avoidance

1. This approach allows the three necessary conditions of deadlock but makes judicious choices to assure that deadlock point is never reached.
2. Deadlock avoidance allows more concurrency than prevention.
3. A decision is made dynamically whether the current resource allocation request will, if granted, potentially lead to a deadlock.

4. It requires the knowledge of future process requests.
5. Two techniques to avoid deadlock:
   - Process Initiation Denial
   - Resource Allocation Denial

Process initiation denial In this technique, do not start a process if its demands might lead to deadlock.

Consider a system of 'n' processes and 'm' different types of resources. Let us define the following vectors and matrices:

Resources $R = (R_1, R_2, \dots R_m)$
R_1: amount of type 1 resources
R_2: amount of type 2 resources
Available $= V = (V_1, V_2, \dots V_m)$

'V' specifies total amount of each resource not allocated to any process.

$$\text{Claim } C = \begin{array}{c} P_1 \\ P_2 \\ P_n \end{array} \begin{bmatrix} C_{11} & C_{12} \cdots & C_{1m} \\ C_{21} & C_{22} \cdots & C_{2m} \\ C_{n1} & C_{n2} \cdots & C_{nm} \end{bmatrix}$$

C_{ij} = requirement of process i for resources j

$$\text{Allocation } A = \begin{array}{c} P_1 \\ P_2 \\ P_n \end{array} \begin{bmatrix} A_{11} & A_{12} \cdots & A_{1m} \\ A_{21} & A_{22} \cdots & A_{2m} \\ A_{n1} & A_{n2} \cdots & A_{nm} \end{bmatrix}$$

A_{ij} = Current allocation to process i of resource j.
The following relationships must hold:

1. All resources are either available or allocated, that is,

$$R_j = V_j + \sum_{i=1}^{n} A_{ij}, \ \forall j$$

2. No process can claim more than the total amount of resources in the system, that is,

$$C_{ij} \le R_j, \ \forall i, j$$

3. No process is allocated more resources of any type than the process originally claimed to need, that is,

$$A_{ij} \le C_{ij}, \ \forall i, j$$

With these properties satisfied, we can define a deadlock avoidance policy that refuses to start a new process if its resource requirements might lead to deadlock. Start a new process P_{n+1} only if

$$R_j \ge C_{(n+1)j} + \sum_{i=1}^{n} C_{ij}, \ \forall j$$

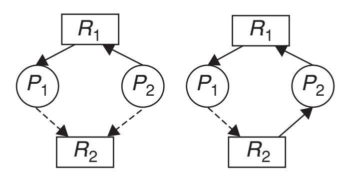
that is, a process is only started if the maximum claim of all current processes plus those of the new process can be met.

Resource allocation denial (OR) banker's algorithm Consider a system with a fixed number of processes and a fixed number of resources. At any time, a process may have zero or more resources allocated to it.

State: The state of a system reflects the current allocation of resources to processes.

Safe state

1. When a process requests an available resource, the system must decide if immediate allocation leaves the system in a safe state.
2. A state is safe if the system can allocate resources to each process in some order and still avoid deadlock.
3. More formally, a system is in safe state if there exists a safe sequence of all processes.
4. A sequence of processes $<P_1, P_2, \dots, P_n>$ is a safe sequence for the current allocation state, if for each P_i, the resource requests that P_i can still make can be satisfied by the currently available resources plus the resources held by all the P_j, with $j < i$.
5. When P_j is finished, P_i can obtain the needed resources, completed its designated task, return its allocated resources and terminates.
6. When P_i terminates, P_{i+1} can obtain its needed resources and so on.
7. If a system is in safe state, no deadlock occurs.
8. If a system is in unsafe state deadlock may occur.
9. Avoidance ensures that a system will never enter an unsafe state.



10. The dotted line in the above graph represents a claim edge, i.e., a process may request that resource sometime in the future.
11. A request can only be granted if it does not result in the formation of a cycle in the graph.
12. If P_2 request R_2, we cannot allocate it, since this would create a cycle.
13. A cycle indicates the system is in *unsafe state*.

Example 1: Consider the following state of a system consisting of three processes and two resources:

$$R = (R_1, R_2) = (5\ 3)$$
$$V = (V_1, V_2) = (2\ 1)$$

$C =$

	R_1	R_2
P_1	4	3
P_2	2	1
P_3	3	3

$A =$

	R_1	R_2
P_1	2	1
P_2	1	1
P_3	0	0

Is this is a safe state?

Solution:
To check whether the state is safe or not, identify whether any one of the three process can run to completion with the resources available, that is, $C_{ij} - A_{ij}$ ″ V_j, ∀j

$$
\begin{array}{cc} & \begin{array}{cc} R_1 & R_2 \end{array} \\ C - A = \begin{array}{c} P_1 \\ P_2 \\ P_3 \end{array} & \begin{pmatrix} 2 & 2 \\ 1 & 0 \\ 3 & 3 \end{pmatrix} \end{array}
$$

We can identify that
[1 0] < [2 1].
∴ P_2 can execute first.
After P_2 execution it will release all its resources then
$V = (2\ 1) + (1\ 1) = (3\ 2)$.
Now P_1 can execute as (2 2) < (3 2).
After that P_1 can release its resources then
$V = (3\ 2) + (2\ 1) = (5\ 3)$
Now P_3 can execute and release the resources after completion.
Hence, the safe sequence is < P_2, P_1, P_3 >.

Example 2: Now suppose for the above system the allocation matrix

$$
A = \begin{pmatrix} 2 & 1 \\ 1 & 1 \\ 2 & 1 \end{pmatrix} \text{ and } V = (0\,0)
$$

Then no process can run to completion as no $C_{ij} - A_{ij}$ ″ V_j, ∀j.
Hence, the system is in unsafe state.

Detection Algorithm for Several Instances of a Resource Type

Safety algorithm

To find out whether or not a system is in a safe state.

Step I: Let 'work' and 'finish' be the two vectors of length m and n.
Initialize: Work = Available and Finish [i] = false;

Step II: Find i such that both:
(a) Finish [i] = false;
(b) Need ″ Work (Need = claim – Allocation)
If no such i exists, go to step 4.

Step III: Work = Work + Allocation
Finish [i] = true
Go to step 2

Step IV: If Finish [i] = true for all i, then the system is in safe state else it is in unsafe state. This algorithm takes $O(m \rightarrow n^2)$ operations to decide whether a state is safe.

Resource–Request algorithm

Let Request$_i$ be the request vector for process, P_i. If Request$_i$[j] = k, the process P_i wants k instances of resource type R_j. When a request for resources is made by process, P_i, the following actions are taken.

Step I: If Request$_i$ ″ Need$_i$, go to step 2. Else raise an exception (error) as the process has exceeded its maximum claim.

Step II: If Request$_i$ ″ Available, go to step 3. Else P_1 must wait, since the resources are not available.

Step IIII: Have the system pretend to have allocated the requested resources to process, P_i, by modifying the state as follows.
Available = Available – Request$_i$
Allocation = Allocation + Request$_i$
Need$_i$ = Need$_i$ – Request$_i$

If the resulting resource–allocation is safe, then the transaction is completed and process, P_i is allocated its resources. However, if the new state is unsafe then P_i must wait for Requesti and the old resource allocation state is restored.

Advantages of deadlock avoidance technique

1. Not necessary to pre-empt and rollback processes.
2. Less restrictive than deadlock prevention.

Disadvantages

1. Future resource requirement must be known in advance.
2. Processes can be blocked for long periods.
3. Exists fixed number of resources for allocation.

Deadlock Detection

1. This technique does not limit resource access or restrict process action.
2. Requested resources are granted to processes whenever possible.

Deadlock detection is used by employing an algorithm that tracks the circular waiting and killing one or more processes so that the deadlock is removed.

The system state is examined periodically to determine if a set of processes is deadlocked.

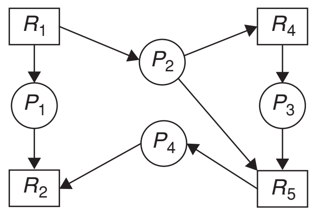
A deadlock is resolved by aborting and restarting a process, relinquishing all the resources that the process held.

For single instance of each resource type If in the RAG, every resource has only one instance (or single instance) then we define a deadlock detection algorithm that uses a variant of the RAG and is called a wait-for-graph.

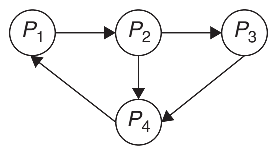
How can we get this graph from RAG? : We can get this by removing the nodes of type resource and collapsing the appropriate edges. Wait-for-graph has a cycle, then there is deadlock in the system.

To detect deadlocks, the system needs to maintain the wait-for-graph and to periodically invoke an algorithm. The complexity of this algorithm is $O(n^2)$ where n is the number of vertices in the graph.

Consider the RAG:



We draw the wait-for-graph by removing all nodes that represents resources and collapsing their edges.



Wait-for-graph

The system is in deadlock state.
Cycle – P_1, P_2, P_4, P_1
Cycle – P_1, P_2, P_3, P_4, P_1

Deadlock Detection Algorithm for Several Instances of Resource Type

Consider the Allocation matrix, A, Request matrix Q (Q_{ij} represents the amount of resource of type j requested by process i), Resource vector R and available vector V.

The algorithm proceeds by marking processes that are not deadlocked. Initially all processes are unmarked.

1. Mark each process that has a row in the Allocation matrix of all zeros.
2. Initialize a temporary vector W to equal the Available vector.
3. Find an index i such that process i is currently unmarked and the ith row of Q is less than or equal to W, that is, $Q_{ik} \le W_k$, for $1 \le k \le M$. If no such row is found, terminate the algorithm.
4. If such a row is found, mark process i and add the corresponding row of the allocation matrix to W. That is, set $W_k = W_k + A_{ik}$ for $1 \le k \le M$. Return to step 3.

A deadlock exists if and only if there are unmarked processes at the end of the algorithm. Each unmarked process is deadlocked.

Example 3: Let the

Request matrix Q =

	R_1	R_2	R_3
P_1	1	1	1
P_2	1	0	0
P_3	1	1	1
P_4	1	1	1

Allocation matrix A =

	R_1	R_2	R_3
P_1	1	1	0
P_2	1	0	0
P_3	0	1	1
P_4	0	1	1

Resource vector $R = (3\ 3\ 3)$
Available Vector $V = (1\ 0\ 1)$
Is deadlock existing in this system?

Solution:
$W = (1\ 0\ 1)$
The request of P_2 is less than W. So $W = W + (1\ 0\ 0) = (2\ 0\ 1)$
So mark P_2. No other unmarked process has a row Q that is less than or equal to W.
Terminate the algorithm.
$\therefore P_1, P_3, P_4$ are in deadlock.

Advantages

1. Never delays process initiation
2. Facilitates online handling

Disadvantages

1. Inherent pre-emption losses

Deadlock Recovery

The possible deadlock recovery strategies are as follows:

1. Abort all deadlocked processes.
2. Back up each deadlocked process to some previously defined checkpoint and restart all processes.
3. Successively abort deadlocked processes until deadlock no longer exists.
4. Successively pre-empt resources until deadlock no longer exists.

Dining Philosophers Problem

Consider the following solution for dining philosophers problem using semaphores:

```
Semaphore fork[5] = {1};
int i;
void philosopher(int i)
{
while (true)
{
think( );
wait(fork[i]);
wait(fork[(i + 1) mod 5]);
eat( );
signal(fork[(i + 1) mod 5]);
signal(fork[i]);
}
}
void main( )
{
Begin(Philosopher(0),Philosopher(1), Philosopher(2), Philosopher(3), Philosopher(4));
}
```

Here, each philosopher picks up first the fork on the left and then the fork on the right. After the philosopher is finished eating, the two forks are placed on the table. But this

solution leads to deadlock, if all of the philosophers are hungry at the same time, they all sit down, they all pick up the fork on their left and they all reach out for the other fork, which is not there.

A refined solution to dining philosophers problem which is deadlock free is shown below:

```
Semaphore fork[5] = {1};
Semaphore room = {4};

int i;
void philosopher(int i)
{
while(true)
{
think( );
wait(room);
wait(fork[i]);
wait(fork[(i + 1) mod 5]);
eat( );
signal(fork[(i + 1) mod 5]);
signal(fork[i]);
signal(room);
}
}
void main ( )
{
Begin
{
(Philosopher (0), Philosopher (1), Philosopher
(2), Philosopher (3), Philosopher (4));
}
}
```

This solution is free from deadlock and starvation.

CPU Scheduling

1. The objective of multi programmed OS is to maximize CPU utilization by having some process running at all times.
2. The objective of time shared OS is to switch the CPU among processes so frequently that the users can interact with each program while it is executing.
3. When there are more than one process ready to execute with the processor, a selection decision needs to be made to pick a process for execution from among the ready processes. This activity is called *process scheduling*.

Scheduling queue: It maintains information of all ready processes for CPU devices. It is maintained as a linked list.

Types of Scheduling Queue

1. ***Job queue:*** It consists of all processes in the system.
2. ***Ready queue:*** It consists of all processes that are residing in the main memory and are ready but waiting to execute on CPU.
3. ***Device queue:*** It consists of processes waiting for a particular I/O device. Each device has its own queue.

Process CPU–I/O Burst Cycle

The execution of process consists of CPU burst and I/O burst. The execution of process starts with CPU burst and I/O burst, which are executed alternatively.

The alternating sequence of CPU and I/O burst are shown below:

Read *a*
Inc *a*
Read *x* } CPU Burst

I/O waiting } I/O Burst
Dec *x*
Store *x* } CPU Burst

I/O waiting } I/O Burst
.
.
.
.

There should be proper balance between CPU bound process and I/O bound process in a schedule.

Scheduler

A process migrates between various scheduling queues throughout its lifetime. The process of selecting processes from the queues is carried out by scheduler.

Types of Processor Scheduling

There are three types of processor scheduling:

1. Long-term scheduling
2. Medium-term scheduling
3. Short-term scheduling

The following figure relates the scheduling functions to the process state transition diagram:

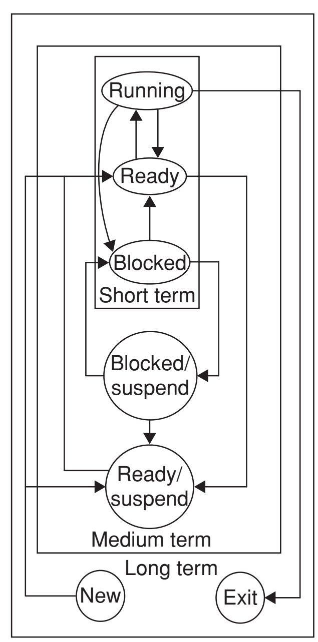


Figure 3 Levels of Scheduling

Long-term Scheduling

1. This is performed when a new process is created. This is also called *job scheduling*.
2. This is a decision whether to add a new process to the set of process that is currently active.
3. It controls the degree of multiprogramming.
4. The long-term scheduler creates processes from the queue when it can.
5. This involves two decisions:
   - The Scheduler must decide when the OS can take on one or more additional processes.
   - The scheduler must decide which job(s) to accept and turn into processes.

Medium-term Scheduling

1. It is a part of swapping function.
2. This is a decision whether to add a process to those that are at least partially in main memory and therefore avail for execution.

Short-term Scheduling

1. It is the decision regarding which ready process to be executed next.
2. This is also known as CPU scheduler.
3. This is invoked whenever an event occurs that may lead to the blocking of the current process or that may provide an opportunity to pre-empt a currently running process in favour of another.
4. Another term involved in short-term scheduling is *dispatcher* which is a module that gives control of the CPU to the process selected by short-term scheduler.

Examples: Clock interrupts, I/O interrupts, OS calls, etc.

Scheduling Algorithms

Scheduling Criteria

The commonly used scheduling criteria can be categorized along two dimensions:

1. User oriented versus system oriented.
2. Performance related versus others.

User-oriented, performance-related criteria

1. ***Turnaround time:*** It is the time taken to execute a process. It is calculated as the interval from the time of submission of a process to the time of completion.
   Turnaround time = waiting time + execution time + time spent in I/O + time spent to get into memory
2. ***Response time:*** Amount of time it takes from when a request was submitted until the first response is produced. It should be minimum.
3. ***Deadlines:*** When process completion deadlines can be specified, the scheduling discipline should subordinate other goals to that of maximizing the percentage of deadlines met.

Waiting time: It is the amount of time that a process spends in ready queue and doing I/O, and it should be minimum.

User-oriented, other criteria

Predictability: A given job should run in about the same amount of time and at about the same cost regardless of the load on the system.

System-oriented, performance-related criteria

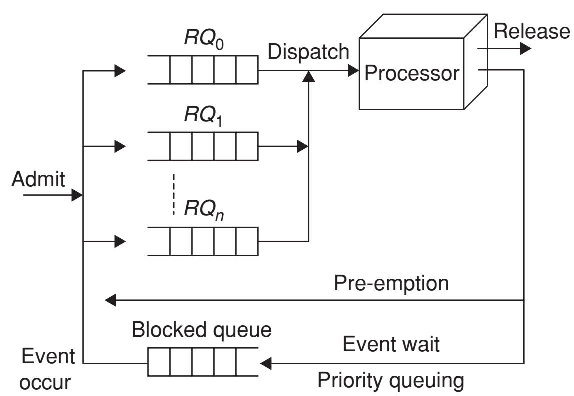
1. ***Throughput:*** The scheduling policy should attempt to maximize the number of processes completed per unit of time. This is a measure of how much work is being performed.
2. ***Processor (CPU) utilization:*** This is the percentage of time that the processor is busy. In real system, it should range from 40–90%.

System-oriented, other criteria

1. ***Fairness:*** No process should suffer from starvation.
2. ***Enforcing priorities:*** Should favour higher priority processes and use Aging technique in order to increase the priority of processes is that wait in the system for long time.
3. ***Balancing resources:*** Should keep the resources of the system busy.

Use of priorities

1. Each process is assigned a priority, and the scheduler will always choose a process of higher priority over one of lower priority.



Here RQ_0, RQ_1,⊃RQ_n are ready queues with priority (RQ_i) > priority (RQ_j) for $i < j$. The scheduler starts with RQ_0 processes, if it is empty choose a process from RQ_1 and so on.

Scheduling Policies

We will discuss the following scheduling algorithms:

1. FCFS
2. Round Robin
3. SPN
4. SRN
5. HRRN
6. Feedback

Before discussing these algorithms, let us discuss some basic concepts:

Selection function

1. Determines which process among ready process, is selected next for execution.
2. This may depend on priority, resource requirement, execution characteristics of process.
3. Execution characteristics of a process include
   w = waiting time
   e = execution time,
   $S = w + e$

Decision mode It is of the following two types:

1. Non-pre-emptive
2. Pre-emptive
   - In non-pre-emptive scheduling, if once the CPU has been allocated to a process, the process can keep the CPU until it releases it, either by terminating or switching to waiting state.
   - In pre-emptive scheduling, CPU can be taken away from a process during execution.

Comparison of non-pre-emptive and pre-emptive scheduling

	Non-pre-emptive Scheduling	Pre-emptive Scheduling
1.	In non-pre-emptive scheduling, if once a process has been allocated CPU then the CPU cannot be taken away from that process.	In pre-emptive scheduling, the CPU can be taken away before the completion of the process.
2.	No preference is given when a higher priority job comes.	It is useful when a higher priority job comes as here the CPU can be snatched from a lower priority process.
3.	The treatment of all processes is fairer.	The treatment of all processes is not fairer as CPU snatching is done either due to constraints or due to higher priority, process request for its execution.
4.	It is a cheaper scheduling method. First come first served is an example.	It is a costlier scheduling method. Round Robin is an example.

First come, first served scheduling (FCFS) The process that requests the CPU first is allocated the CPU first. It is non-pre-emptive scheduling and average waiting time is quite long.

Example 4: Consider the following processes:

Process	Cpu Burst Time (Millisecond)
P_1	20
P_2	5
P_3	3

Find the average waiting time.

Solution:
Suppose they are in the order P_1, P_2, P_3 at time 0. So, Gantt chart is

P_1	P_2	P_3

0 20 25 28

$$\text{Average waiting time} = \frac{(0+20+25)}{3}$$
$$= 15 \text{ ms}$$

If they arrived in order P_3, P_2, P_1 then, Gantt chart is

P_3	P_2	P_1

0 3 8 28

$$\text{Average waiting time} = \frac{0+3+8}{3} = \frac{11}{3}$$
$$= 3.67 \text{ ms}$$

Notes:

1. Throughput is not that much emphasized.
2. Response time may be high especially if there is a large variance in process execution times.
3. Minimum overhead required.
4. It penalizes short processes, also penalizes I/O bound processes.
5. There is no possibility of starvation.

Advantages

1. Simple and brutally fair.
2. It is suitable for batch systems.

Disadvantages

1. The average waiting time is not minimal.
2. Not suitable for time sharing systems like Unix.
3. ***Convoy effect:*** Short process behind long process results in lower CPU utilization.

Round Robin scheduling

1. It is designed for time sharing system.
2. Similar to FCFS with pre-emption added.
3. Each process gets a small central CPU time (a time slice) usually 10 – 100 ms.
4. After time slice has elapsed and added to the end of the ready queue.
5. The scheduler picks the first process from the ready queue, sets a timer to interrupt after one time quantum and then dispatches the process. One of the following happens.
6. The process may have a CPU burst of less than 1 time quantum. (or)
7. CPU burst time of the currently executing process is longer than one time quantum. In this case, the timer will go off, cause an interrupt, a context switch is then

executed and the process is put at the tail of the ready queue.
8. Average waiting time is quite long.

Performance of Round Robin scheduling

Let us assume that we have onlys one process of 10 time units.

Process time = 10	Quantum	Switch
0 10	12	0
0 6 10	6	1
0 1 2 3 4 5 6 7 8 9 10	1	9

Example 5: Consider the following processes, arrival times and CPU processing requirements with Round Robin scheduling algorithm.

Process	CPU time	Arrival time
A	8	0
B	1	1
C	2	3
D	1	4
E	5	2

What will be the mean turnaround time if time quantum is 4 msec?

Solution:
Plotting the Gantt chart

A	*B*	*E*	*C*	*D*	*A*	*E*

0 4 5 9 11 12 16 17

Turnaround time = Finish time – Arrival time
TAT of $A = 16 - 0 = 16$
$B = 5 - 1 = 4$
$C = 11 - 3 = 8$
$D = 12 - 4 = 8$
$E = 17 - 2 = 15$

$$\text{Mean Turnaround time } = \frac{16+4+8+8+15}{5}$$
$$= 10.2 \text{ msec}$$

1. If there are n processes in the ready queue and time quantum q, then each process gets $\frac{1}{n}$ of the CPU time in chunks of at most q time units at once.
2. No process waits more than $(n - 1)q$ time units until the next time quantum.
3. The performance of Round Robin depends on time slice. If it is larger it is same as FCFS. If q is very small overhead is too high as the number of context switches increases.

Notes:
1. Throughput is low if quantum is too small.
2. Provides good response time for short processes.
3. Minimum overhead.
4. All processes treated fairly.
5. No starvation.

Shortest process next (SPN)

1. This is a non-pre-emptive policy in which the process with the shortest expected processing time is selected next.
2. A short process will jump to the head of the queue past longer jobs.

Example 6: Consider the following process, such that all have arrived at time = 0

Process	Burst time
P_1	5
P_2	9
P_3	6
P_4	3

Find the average waiting time using SPN.

Solution: Gantt chart is

P_4	P_1	P_3	P_2

0 3 8 14 23

$$\text{Average waiting time } = \frac{0+3+8+14}{4} = 6.25 \text{ ms}$$

Notes:

1. Difficulty with this policy is that we need to know or at least estimate the required processing time of each process.
2. High throughput is possible.
3. Provides good response time for short processes.
4. High overhead.
5. It penalizes long processes.
6. There is a possibility of starvation.

Shortest remaining time (SRT)

1. It is a pre-emptive version of SPN.
2. Here the scheduler always chooses the process that has the shortest expected remaining processing time.
3. When a new process joins the ready queue, it may in fact have a shorter remaining time than the currently running process.
4. Accordingly, the scheduler may pre-empt the current process when a new process becomes ready.

Example 7: Consider the following process. Find the average waiting time for SRT.

Process	Arrival time	Burst time
P_1	0	8
P_2	1	4
P_3	2	9
P_4	3	5

Solution: Gantt chart

P_1	P_2	P_4	P_1	P_3

0 1 5 10 17 26

So average waiting time

$$\frac{(10-1)+(1-1)+(17-2)+(5-3)}{4}$$

$$\frac{9+0+15+2}{4}=\frac{26}{4}$$

$$=6.5 \text{ ms}$$

Here P_3 starts at time 17 but the arrival time was at 2. So waiting time of P_3 will be $(17-2)$.

Notes:

1. High throughput.
2. Provides good response time.
3. High overhead.
4. Penalizes long processes.
5. Starvation is possible.

Highest Response Ratio Next (HRRN)

This algorithm works on the principle the executes the job first which has the highest response ratio. We define response ratio as the ratio between turnaround time and response time.

$$\text{Response Ratio } = \frac{(W+S)}{S}, \text{ where}$$

W – Time spend waiting for the processor
S – Service time
This response ratio is also named as normalized turnaround time.

Example 8: Consider 5 processes with their arrival and service times:

Process	Arrival time	Service time
$P1$	0	3
$P2$	2	6
$P3$	4	4
$P4$	6	5
$P5$	8	2

What is the average turnaround time using HRRN technique?

Solution:
Gantt chart

P_1	P_2	P_3	P_5	P_4

0 3 9 13 15 20

Average turnaround time

$$=\frac{3+(6+1)+(4+5)+(5+9)+(2+5)}{5}=\frac{40}{5}=8 \text{ ms}$$

Notes:

1. It is a non-pre-emptive scheduling algorithm.
2. High throughput.
3. Provides good response time.
4. High overhead.
5. Good balance of any type processes.
6. No starvation.

Multilevel feedback queue scheduling

1. In multilevel queue scheduling algorithm, processes are permanently assigned to a queue on entry to the system. Processes cannot move between queues.
2. Processes can move between queues. If a process uses too much CPU time, it will be moved to a lower priority queue.
3. I/O bound and interactive processes are put into higher priority queue.
4. A process that waits too long in a lower priority queue may be moved to a higher priority queue. This form of aging prevents starvation.

In general, a multilevel feedback queue scheduler is defined by following parameters:

1. The number of queues.
2. The scheduling algorithm for each queue.
3. The method used to determine when to upgrade a process to a higher priority queue.
4. The method used to determine when to denote a process to a lower priority queue.
5. The method used to determine in which queue a process will enter when process needs service.

Notes:

1. Pre-emptive at time quantum.
2. Throughput is not that much emphasized.
3. Response time is not that much emphasized.
4. High overhead.
5. Favours I/O bound processes.
6. Starvation is possible.

Exercises

Practice Problem 1

Directions for questions 1 to 19: Select the correct alternative from the given choices.

1. Consider the following processes; find the average waiting time using non-pre-emptive priority scheduling?

Process	Arrival time (ms)	Burst time (ms)	Priority
P_0	0	10	5
P_1	1	6	4
P_2	3	2	2
P_3	5	4	0

(A) 2.36 ms (B) 0.31 ms
(C) 7.75 ms (D) 13.25 ms

2. Consider a set of five processes whose arrival time, CPU times needed are given below.

Process	CPU time (in m sec)	Arrival time (in msec)
P_1	10	5
P_2	5	2
P_3	3	0
P_4	20	4
P_5	2	3

If the CPU scheduling policy is SJF, find the average waiting time (with pre-emption).
(A) 4.8 ms (B) 5.6 ms
(C) 2.16 ms (D) 2.8 ms

3. Consider the following snapshot of a system:

	Allocation				Max				Available			
	A	*B*	*C*	*D*	*A*	*B*	*C*	*D*	*A*	*B*	*C*	*D*
P_0	0	0	1	2	0	0	1	2	1	5	2	0
P_1	1	0	0	0	1	7	5	0				
P_2	1	3	5	4	2	3	5	6				
P_3	0	6	3	2	0	6	5	2				
P_4	0	0	1	4	0	6	5	6				

Which of the following is true?
(i) The system is in a safe state.
(ii) If a request from process *P*, arrives for (0, 4, 2, 0). Then the request can be granted.
(A) Only (i) (B) Only (ii)
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

4. In a Round Robin scheduling context switch time is 4 units, the average process running time before blocking is 6 units then CPU efficiency is
(A) 0.2 (B) 0.4
(C) 0.6 (D) 0.1

5. A short-term scheduler executes at least once every 20 msec. If it takes 2 msec to decide to execute a process for 2 msec, what is the percentage of CPU time wasted?
(A) 8% (B) 9%
(C) 10% (D) 11%

6. Consider a system which has n resources of the same type. The n resources are shared among three processes *A*, *B*, *C*, which have high demands of 3, 5, 6, respectively. For what value of n will deadlock not occur?
(A) 11 (B) 10
(C) 9 (D) 15

7. A comparative study of scheduling algorithm was performed, the average arrival time in the queue is 5 *m* sec and waiting time of the processes is 10 msec. What is the average queue length of the waiting processes?
(A) 50 (B) 60
(C) 70 (D) 80

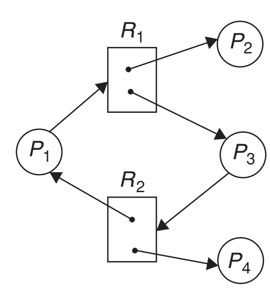
8. A CPU scheduling algorithm determines an order for the execution of its scheduled processes. Given five processes to be scheduled on one processor, how many possible different schedules are there?
(A) 50 (B) 100
(C) 120 (D) 150

9. Consider the following set of jobs (processes) along with their Arrival Time (AT), start time (ST) and Finish Time (FT). Find weighted turnaround time.

Job no.	AT	ST	FT
1	10.0	10.0	10.3
2	10.2	10.3	10.8
3	10.4	10.8	10.9
4	10.5	10.9	11.3
5	10.8	11.3	11.4

(A) 3.04 (B) 2.04
(C) 4.04 (D) 0.56

10. Is the following resource allocation graph in a deadlock state?



(A) Yes (B) No
(C) Not predictable (D) Insufficient data

11. Starvation of longer jobs happens in one of the following scheduling algorithm?
(A) Shortest run remaining time first
(B) Round Robin
(C) Highest response ratio next
(D) First-come first-served

12. Suppose n processes, $P_1 \ldots P_n$ share n identical resource units, which can be reserved and released one at a time. The maximum resource requirement of process P_i is S_i, where $S_i > 0$. Which one of the following is a sufficient condition for ensuring that deadlock does not occur?
(A) $+ i, S_i < m$ (B) $+ i, S_i < n$
(C) $\sum_{i=1}^{n} S_i < (m+n)$ (D) $\sum_{i=1}^{n} S_i < (m*n)$

13. A system with following processes and resources exists. Check the system for safe state and find the safe sequence of processes

	Allocation			Max			Available		
	X	Y	Z	X	Y	Z	X	Y	Z
P_0	0	1	0	7	5	3	3	3	2
P_1	2	0	0	3	2	2			
P_2	3	0	2	9	0	2			
P_3	2	1	1	2	2	2			
P_4	0	0	2	4	3	3			

(A) $< P_1, P_3, P_4, P_2, P_0 >$
(B) $< P_3, P_4, P_2, P_0, P_1 >$
(C) $< P_2, P_4, P_0, P_1, P_3 >$
(D) The system is in unsafe state.

14. Does the below statements be executed concurrently?
$S_1 : a = x + y$
$S_2 : b = z + 1$
(A) Yes (B) No
(C) Not predictable (D) None of the above

15. Let A, B, C be three jobs. Their arrival time and execution time are shown below. By applying monoprogramming and multiprogramming (use Round Robin with time slice 1 unit) approaches, calculate the amount of reduction in turnaround time?

Job	Arrival time	Execution time
A	1	2
B	2	6
C	3	1

(A) 3.33 (B) 4.33
(C) 5.33 (D) 2.33

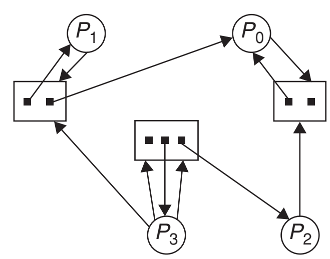
16. Consider a system with three processes A, B, C with 15 tape drivers. Process A has 4 tape drives but requires 14 tape drives.
Process B has 5 tape drives but requires 9 tape drives.
Process C has 3 tape drives but requires 7 tape drives.
Among the following processes which will enter the deadlock state?
(A) A, B only (B) A, B, C
(C) A, C only (D) B, C only

17. Assume that the following jobs are to be executed on a uniprocessor system:

Job id	CPU burst time
P	4
Q	1
R	8
S	1
T	2

The jobs are assumed to have arrived at 0, and in the order P, Q, R, S and T. Calculate the departure with time slice (completion time) for job P if scheduling is Round Robin with time slices of 1 unit (slice).
(A) 4 (B) 10
(C) 11 (D) 12

Common data for questions 18 and 19: Consider the following Resource Allocation Graph:



18. The system is in a deadlock state. This remark is:
(A) True (B) False
(C) Impossible to determine
(D) Unpredictable

19. Which one is a safe sequence?
(A) P_0, P_1, P_2, P_3 (B) P_1, P_0, P_2, P_3
(C) P_2, P_0, P_1, P_3 (D) Both (A) and (C)

Practice Problem 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Let there be five processes (P_1 to P_5) and three resource types A, B, C.
Resource type A has 10 instances,
Resource type B has 5 instances,
Resource type C has 7 instances.
Suppose that at time T_0, the following snapshot of the system has been taken.

	Allocation			Max			Available		
P_1	0	1	0	7	5	3	3	3	2
P_2	2	0	0	3	2	2			
P_3	3	0	2	9	0	2			
P_4	2	1	1	2	8	2			
P_5	0	0	2	4	3	3			

Which of the following statement is true?

(A) The system is in safe state.
(B) The system has process initiation denial problem.
(C) No process causes initiation denial
(D) Both (A) and (C)

2. Consider three CPU intensive processes, which require 20, 30 and 40 time units and arrive at times 0, 2 and 4, respectively. How many context switches are needed if the operating system implements a shortest remaining time first scheduling algorithm? Do not count the context switches at time zero and at the end.
(A) 0 (B) 1
(C) 2 (D) 3

3. Consider the set of processes P_1 to P_5 with the following CPU burst times. Find the average turnaround time using shortest remaining time first.

Process	CPU burst time	Arrival time
P_1	3	0
P_2	6	2
P_3	4	4
P_4	5	6
P_5	2	8

(A) 1.3 ms (B) 3.5 ms
(C) 5.8 ms (D) 7.2 ms

4. All processes are arriving at time 0, find the average waiting time.

Process	Burst time	Priority
P_1	10	3
P_2	1	1
P_3	2	3
P_4	1	4
P_5	5	2

(A) 8.2 ms (B) 4.1 ms
(C) 2.0 ms (D) 1.3 ms

5. Consider a set of three processes P_1, P_2 and P_3 with their priorities and arrival times as given below.

Process	Burst time	Priority	Arrival time
P_1	10	3	0
P_2	5	2	1
P_3	2	1(highest)	2

Find the average waiting time.
(A) 1 ms (B) 2 ms
(C) 3 ms (D) 4 ms

6. The portion of the process scheduler in an OS that dispatches processes is concerned with:
(A) assigning ready processes to the CPU
(B) activating suspended I/O bound processes
(C) temporarily suspending processes when the CPU load is too great.
(D) All the above

7. In a time-sharing OS, when the time slot given to a process is completed, the process goes from the running state to the
(A) blocked state (B) ready state
(C) suspended state (D) terminated state

8. On a system with n CPUs, what is the maximum number of processes that can be in the ready state?
(A) n processes
(B) No process can be in ready state
(C) There is no limit to the number of processes in the ready state
(D) None of the above

9. Consider a set of n tasks with known runtimes $r_1, r_2, \ldots, r_n$ to be run on a uniprocessor machine. Which of the following processor scheduling algorithms will result in the maximum throughput?
(A) Round Robin
(B) SJF
(C) Highest response ratio next
(D) First-come first-served

10. Match the following:

A	Critical region	I	Hoare's monitor
B	Wait/signal	II	Mutual exclusion
C	Working set	III	Principle of locality
D	Deadlock	IV	Circular wait

(A) A – II, B – I, C – III, D – IV
(B) A – I, B – II, C – III, D – IV
(C) A – II, B – I, C – IV, D – III
(D) A – I, B – II, C – IV, D – III

11. Consider three processes A, B, C to be scheduled as per SRT algorithm. A is known to be scheduled first and when A has been running for 7 units of time, C has arrived. C has run for 1 unit of time when B has arrived and completed running in 2 units of time, what could be the minimum time of executions for A and C?
(A) 11 and 4 (B) 11 and 3
(C) 12 and 3 (D) 12 and 4

12. Select the correct statements from below:
(i) SRT and SPN can cause starvation for larger processes.
(ii) FCFS can potentially block small processes in favour of much larger processes.
(iii) Round Robin algorithm gives fair treatment to all the processes.
(iv) FCFS is a pre-emptive algorithm.
(v) The throughput for Round Robin is high even for small time slices.
(A) (i), (ii), (iii) (B) (i), (ii), (iv)
(C) (iii), (iv), (v) (D) (i), (ii), (iii), (v)

13. Three processes share four resource units that can be reserved and released only one at a time. Each process needs a maximum of two units. Then
(A) there is a possibility of deadlock
(B) no deadlock will occur

(C) there will be a circular wait
(D) nothing can be predicted about dead lock.

14. N processes share M resource units that can be reserved and released only one at a time. The maximum need of each process does not exceed M and the sum of all maximum needs is less than $M + N$, then
(A) there is a possibility of deadlock
(B) there will be no deadlock
(C) circular wait exists
(D) nothing can be predicted about dead lock.

15. Which of the following scheduling algorithms could result in starvation?
(A) First-come, first-served
(B) Shortest job first
(C) Round Robin
(D) Highest response ratio next

Previous Years' Questions

1. Consider three processes (process id 0, 1, 2, respectively) with compute bursts 2, 4 and 8 time units. All processes arrive at time zero. Consider the longest remaining time first (LRTF) scheduling algorithm. In LRTF ties are broken by giving priority to the process with the lowest process id. The average turnaround time is: **[2006]**
(A) 13 units (B) 14 units
(C) 15 units (D) 16 units

2. Consider three processes, all arriving at zero, with total execution time of 10, 20 and 30 units, respectively. Each process spends the first 20% of execution time doing I/O, the next 70% of time doing computation, and the last 10% of time doing I/O again. The operating system uses a shortest remaining compute time first scheduling algorithm and schedules a new process either when the running process gets blocked on I/O or when the running process finishes its compute burst. Assume that all I/O operations can be overlapped as much as possible. For what percentage of time does the CPU remain idle? **[2006]**
(A) 0% (B) 10.6%
(C) 30.0% (D) 89.4%

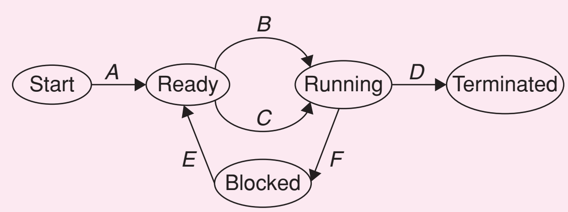
3. A single processor system has three resource types X, Y and Z, which are shared by three processes. There are five units of each resource type. Consider the following scenario, where the column *alloc* denotes the number of units of each resource type allocated to each process, and the column *request* denotes the number of units of each resource type requested by a process in order to complete execution. Which of these processes will finish *last*?

	alloc			request		
	X	Y	Z	X	Y	Z
P_0	1	2	1	1	0	3
P_1	2	0	1	0	1	2
P_2	2	2	1	1	2	0

(A) P_0 **[2007]**
(B) P_1
(C) P_2
(D) None of the above, since the system is in a deadlock.

4. Which of the following is *not* true of deadlock prevention and deadlock avoidance schemes? **[2008]**
(A) In deadlock prevention, the request for resources is always granted if the resulting state is safe
(B) In deadlock avoidance, the request for resources is always granted if the result state is safe
(C) Deadlock avoidance is less restrictive than deadlock prevention
(D) Deadlock avoidance requires knowledge of resource requirements *a priori*

5. In the following process state transition diagram for a uniprocessor system, assume that there are always some processes in the ready state: **[2009]**



Now consider the following statements:
I. If a process makes a transition D, it would result in another process making transition A immediately.
II. A process P_2 in blocked state can make transition E, while another process P_1 is in running state.
III. The OS uses pre-emptive scheduling.
IV. The OS uses non-pre-emptive scheduling.
Which of the above statements are true?
(A) I and II (B) I and III
(C) II and III (D) II and IV

6. Which of the following statements are true?
I. Shortest remaining time first scheduling may cause starvation
II. Pre-emptive scheduling may cause starvation
III. Round Robin is better than FCFS in terms of response time **[2010]**
(A) I only (B) I and III only
(C) II and III only (D) I, II and III

7. A system has n resources $R_0, \ldots, R_{n-1}$, and k processes $P_0, \ldots P_{k-1}$. The implementation of the resource request logic of each process P_i, is as follows:

```
if (i% 2 = = 0) {
if (i<n) request R_i;
if (i+2<n) request R_i+2;
}
else {
if (i<n) request R_n-i;
if (i+2<n) request R_n-i-2;
}
```

In which one of the following situations is a deadlock possible? **[2010]**

(A) $n = 40, k = 26$ (B) $n = 21, k = 12$
(C) $n = 20, k = 10$ (D) $n = 41, k = 19$

8. Consider the following table of arrival time and burst time for three processes P_0, P_1 and P_2. **[2011]**

Process	Arrival time	Burst time
P_0	0 ms	9 ms
P_1	1 ms	4 ms
P_2	2 ms	9 ms

The pre-emptive shortest job first scheduling algorithm is used. Scheduling is carried out only at arrival or completion of processes. What is the average waiting time for the three processes?

(A) 5.0 ms (B) 4.33 ms
(C) 6.33 ms (D) 7.33 ms

9. Consider the three processes, P_1, P_2 and P_3 as shown in the table. **[2012]**

Process	Arrival time	Time units required
P_1	0	5
P_2	1	7
P_3	3	4

The completion order of the three processes under the policies FCFS and RR_2 (Round Robin scheduling with CPU quantum of 2 time units) are

(A) **FCFS:** P_1, P_2, P_3 **RR2:** P_1, P_2, P_3
(B) **FCFS:** P_1, P_3, P_2 **RR2:** P_1, P_3, P_2
(C) **FCFS:** P_1, P_2, P_3 **RR2:** P_1, P_3, P_2
(D) **FCFS:** P_1, P_3, P_2 **RR2:** P_1, P_2, P_3

10. A scheduling algorithm assigns priority proportional to the waiting time of a process. Every process starts with priority zero (the lowest priority). The scheduler re-evaluates the process priorities every T time units and decides the next process to schedule. Which one of the following is TRUE if the processes have no I/O operations and all arrive at time zero? **[2013]**

(A) This algorithm is equivalent to the first-come-first-serve algorithm.
(B) This algorithm is equivalent to the Round Robin algorithm.
(C) This algorithm is equivalent to the shortest-job-first algorithm.
(D) This algorithm is equivalent to the shortest-remaining-time-first algorithm.

11. An operating system uses the *Banker's algorithm* for deadlock avoidance when managing the allocation of three resource types X, Y and Z to three processes P_0, P_1, and P_2. The table given below presents the current system state. Here, the *allocation* matrix shows the current number of resources of each type allocated to each process and the *Max* matrix shows the maximum number of resources of each type required by each process during its execution. **[2014]**

	Allocation			Max		
	X	*Y*	*Z*	*X*	*Y*	*Z*
P_0	0	0	1	8	4	3
P_1	3	2	0	6	2	0
P_2	2	1	1	3	3	3

There are three units of type X, two units of type Y and two units of type Z still available. The system is currently in a *safe* state. Consider the following independent requests for additional resources in the current state:

REQ1: P_0 requests 0 units of X, 0 units of Y and two units of Z

REQ 2: P_1 requests two units of X, 0 units of Y and 0 units of Z

Which one of the following is true?

(A) Only REQ1 can be permitted
(B) Only REQ2 can be permitted
(C) Both REQ1 and REQ2 can be permitted
(D) Neither REQ1 nor REQ2 can be permitted

12. Consider the following set of processes that need to be scheduled on a single CPU. All the times are given in milliseconds.

Process name	Arrival time	Execution time
A	0	6
B	3	2
C	5	4
D	7	6
E	10	3

Using the *shortest remaining time first* scheduling algorithm, the average process turnaround time (in msec) is ——. **[2014]**

13. Three processes A, B and C each execute a loop of 100 iterations. In each iteration of the loop, a process performs a single computation that requires t_c CPU milliseconds and then initiates a single I/O operation that lasts for t_{io} milliseconds. It is assumed that the computer where the processes execute has sufficient number of I/O devices and the OS of the computer assigns different I/O devices to each process. Also, the scheduling overhead of the OS is negligible. The processes have the following characteristics:

Process id	t_c	t_{io}
A	100 ms	500 ms
B	350 ms	500 ms
C	200 ms	500 ms

The processes *A*, *B* and *C* are started at times 0, 5 and 10 milliseconds, respectively, in a pure time sharing system (Round Robin scheduling) that uses a time slice of 50 milliseconds. The time in milliseconds at which process *C* would *complete* its first I/O operation is ——— **[2014]**

14. A system contains three programs and each requires three tape units for its operation. The minimum number of tape units which the system must have such that deadlocks never arise is ———. **[2014]**

15. An operating system uses *shortest remaining time first* scheduling algorithm for pre-emptive scheduling of processes. Consider the following set of processes with their arrival times and CPU burst times (in milliseconds):

Process	Arrival time	Burst time
P_1	0	12
P_2	2	4
P_3	3	6
P_4	8	5

The average waiting time (in milliseconds) of the processes is _____. **[2014]**

16. Consider a uniprocessor system executing three tasks T_1, T_2 and T_3, each of which is composed of an infinite sequence of jobs (or instances) which arrive periodically at intervals of 3, 7 and 20 milliseconds, respectively. The priority of each task is the inverse of its period, and the available tasks are scheduled in order of priority, with the highest priority task schedule first. Each instance of T_1, T_2 and T_3 requires an execution time of 1, 2 and 4 milliseconds, respectively. Given that all tasks initially arrive at the beginning of the 1st millisecond and task preemptions are allowed, the first instance of T_3 completes its execution at the end of ________ milliseconds. **[2015]**

17. A system has 6 identical resources and *N* processes competing for them. Each process can request atmost 2 resources. Which one of the following values of *N* could lead to a deadlock? **[2015]**

(A) 1 (B) 2
(C) 3 (D) 4

18. The maximum number of processes that can be in Ready state for a computer system with n CPUs is **[2015]**

(A) n (B) n^2
(C) 2^n (D) Independent of n

19. Consider the following policies for preventing deadlock in a system with mutually exclusive resources. **[2015]**

(1) Processes should acquire all their resources at the beginning of execution. If any resource is not available, all resources acquired so far are released.

(2) The resources are numbered uniquely, and processes are allowed to request for resources only in increasing resource numbers.

(3) The resources are numbered uniquely, and processes are allowed to request for resources only in decreasing resource numbers.

(4) The resources are numbered uniquely. A process is allowed to request only for a resource with resource number larger than its currently held resources.

Which of the above policies can be used for preventing deadlock?

(A) Any one of 1 and 3 but not 2 or 4
(B) Any one of 1, 3 and 4 but not 2
(C) Any one of 2 and 3 but not 1 or 4
(D) Any one of 1, 2, 3 and 4

20. For the processes listed in the following table, which of the following scheduling schemes will give the lowest average turnaround time? **[2015]**

Process	Arrival Time	Processing Time
A	0	3
B	1	6
C	4	4
D	6	2

(A) First Come First Serve
(B) Non-preemptive Shortest Job First
(C) Shortest Remaining Time
(D) Round Robin with Quantum value two

21. Consider an arbitrary set of CPU - bound processes with unequal CPU burst lengths submitted at the same time to a computer system. Which one of the following process scheduling algorithms would minimize the average waiting time in the ready queue? **[2016]**

(A) Shortest remaining time first
(B) Round-robin with time quantum less than the shortest CPU burst
(C) Uniform random
(D) Highest priority first with priority proportional to CPU burst length

22. Consider the following processes, with the arrival time and the length of the CPU burst given in milliseconds. The scheduling algorithm used is preemptive shortest remaining - time first.

Process	Arrival Time	Burst Time
P_1	0	10
P_2	3	6

P_3	7	1
P_4	8	3

The average turn around time of these processes is ____ milliseconds. **[2016]**

23. Consider the following CPU processes with arrival times (in milliseconds) and length of CPU bursts (in milliseconds) as given below :

Process	Arrival time	Burst time
P1	0	7
P2	3	3
P3	5	5
P4	6	2

If the pre-emptive shortest remaining time first scheduling algorithm is used to schedule the processes, then the average waiting time across all processes is milliseconds. **[2017]**

24. A system shares 9 tape drives. The current allocation and maximum requirement of tape drives for three processes are shown below:

Process	Current Allocation	Maximum Requirement
P1	3	7
P2	1	6
P3	3	5

Which of the following best describes current state of the system? **[2017]**

(A) Safe. Deadlocked
(B) Safe. Not Deadlocked
(C) Not Safe. Deadlocked
(D) Not Safe, Not Deadlocked

25. Consider the set of processes with arrival time (in milliseconds). CPU burst time (in milliseconds). and priority (0 is the highest priority) shown below. None of the processes have I/O burst time.

Process	Arrival Time	Burst Time	Priority
P_1	0	11	2
P_2	5	28	0
P_3	12	2	3
P_4	2	10	1
P_5	9	16	4

The average waiting time (in milliseconds) of all the processes using preemptive priority scheduling algorithm is________. **[2017]**

26. Consider a system with 3 processes that share 4 instances of the same resource type. Each process can request a maximum of K instances. Resource instances can be requested and released only one at a time. The largest value of K that will always avoid deadlock is ______. **[2018]**

27. In a system, there are three types of resources: E, F and G. Four processes P_0, P_1, P_2 and P_3 execute concurrently. At the outset, the processes have declared their maximum resource requirements using a matrix named Max as given below. For example, Max[P_2, F] is the maximum number of instances of F that P_2 would require. The number of instances of the resources allocated to the various processes at any given state is given by a matrix named Allocation.

Consider a state of the system with the Allocation matrix as shown below, and in which 3 instances of E and 3 instances of F are the only resources available.

Allocation			
	E	F	G
P_0	1	0	1
P_1	1	1	2
P_2	1	0	3
P_3	2	0	0

Max			
	E	F	G
P_0	4	3	1
P_1	2	1	4
P_2	1	3	3
P_3	5	4	1

From the perspective of deadlock avoidance, which one of the following is true? **[2018]**

(A) The system is in safe state.
(B) The system is not in safe state, but would be safe if one more instance of E were available.
(C) The system is not in safe state, but would be safe if one more instance of F were available.
(D) The system is not in safe state, but would be safe if one more instance of G were available.

Chapter 4

Memory Management and Virtual Memory

LEARNING OBJECTIVES

- *Basic concepts*
- *Memory management requirements*
- *Relocation and memory mapping techniques*
- *Placement algorithm*
- *Dynamic partitioning*
- *Placement algorithm*
- *Buddy system*
- *Non-contiguous storage allocation methods*
- *Paging*
- *Segmentation*
- *Page table structure*
- *Hierarchical page table*
- *Inverted page table*
- *Address translation in a segmentation system*

Basic Concepts

Uniprogramming system Main memory is divided into two parts as follows:

1. Operating system (OS) part
2. Program part (which is currently being executed)

Multiprogramming system Here the user part of memory must be further subdivided to accommodate multiple processes.

The task of subdivision is carried out dynamically by the OS and is known as memory management.

Memory Hierarchy

The triangle in Figure 1 gives the hierarchy of memory. The memory hierarchy shows the performance issues.

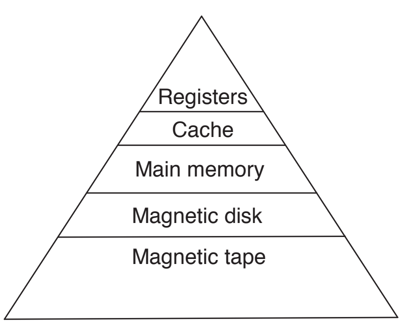

Figure 1 Memory hierarchy.

The memory hierarchy has different types of storage system in computers which are arranged in hierarchy, with respect to speed and cost.

If one moves down the hierarchy, access time increases, the cost per bit decreases, the memory capacity increases and memory access frequency by the processor decreases.

The registers, cache and main memory are volatile, whereas magnetic disc and magnetic tapes are non-volatile storage devices.

Memory Management Requirements

Memory management requirements are as follows:

1. Relocation
2. Protection
3. Sharing
4. Logical organization
5. Physical organization

Relocation

1. The role of relocation, the ability to execute processes independently from their physical location in memory, is central for memory management.
2. In a general purpose multiprogramming environment, a program cannot know in advance what processes will be running in memory when it is executed, nor how much memory the system has available for it, nor where it is located.
3. Hence program relocation is required such that a program must be compiled and linked in such a way that it can later be loaded starting from an unpredictable address in memory, an address that can even change during the execution of the process itself, if any swapping occurs.

4. The basic requirement for program relocation is that all the references to memory it makes during execution must not contain absolute (physical) address of memory cells, but must be generated relatively, that is, as a distance measured in number of contiguous memory words, from some known point.

Protection

Each process should be protected against unwanted interference by other processes, whether accidental or intentional.

Thus, programs in other processes should not be able to reference memory locations in a process for reading or writing purpose without permission.

Sharing

1. Any protection mechanism must have the flexibility to allow several processes to access the same portion of main memory.
2. Processes that are cooperating on some task may need to share access to the same data structure.
3. The memory management system must therefore allow controlled access to shared areas of memory without compromising essential protection.

Logical Organization

Main memory in a computer system is organized as a linear address space consisting of a sequence of bytes or words. But most of the programs are organized into modules.

If the OS and hardware can effectively deal with user programs and data in the form of modules, then there are some advantages.

1. Modules can be written and compiled independently.
2. Different degrees of protection can be given to different modules.
3. It is better to share modules among processes.

Physical Organization

Computer memory is organized in two levels:

1. Main memory
2. Secondary memory

The flow of information between these two modules is a major concern. If this is assigned to user, then there are some problems:

1. ***Overlaying*** may be possible. In overlaying concept, the various modules of a program can be assigned to the same region of memory, which causes wastage of programmer time.
2. The programmer does not know at the time of coding how much space will be available or where that space will be. So it must be handled by the system.

Address binding Addresses may be represented in different ways during the program execution:

1. Addresses in source program are generally symbolic.
2. A complier will typically bind these symbolic addresses to relocatable addresses.
3. The linkage editor or loader will in turn bind the relocatable addresses to absolute addresses.

So the binding of instructions and data to memory addresses can be done at any step along the way:

1. Compile time
2. Load time
3. Execution time

Compile time If you know at compile time where the process will reside in memory, then absolute code can be generated.

Load time If it is not known at compile time where the process will reside in memory, then the compiler must generate relocatable code.

Execution time If the process can be moved during its execution from one memory segment to another, then binding must be delayed until run time.

Logical versus Physical Address Apace

Logical address An address generated by the CPU is commonly referred to as a logical address.

Physical address An address seen by the memory unit, that is, one loaded into MAR is referred as a *physical address*.

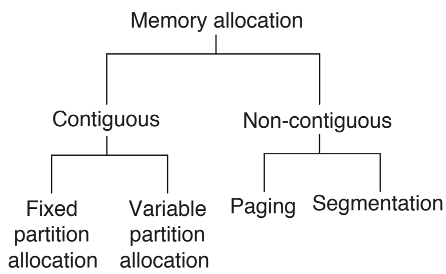
Notes:

1. Logical and physical addresses differ in execution time address-binding scheme.
2. Logical and physical addresses are same in compile time and load time address-binding schemes.
3. The run-time mapping from logical to physical address is done by a hardware device called the *memory management unit* (MMU).

Memory Mapping Techniques

The principle operation of memory management is to bring processes into main memory for execution by the processor. Let's now discuss various memory management techniques as follows:

1. Fixed partitioning
2. Dynamic partitioning
3. Simple paging
4. Simple segmentation
5. Virtual memory paging
6. Virtual memory segmentation.



Contiguous Storage Allocation

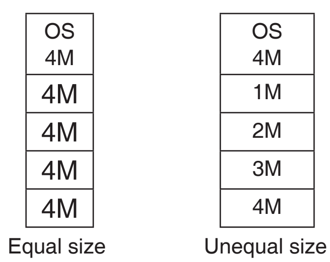
In this allocation, a memory resident program occupies a single contiguous block of memory.

Fixed/Static Partitioning

The main memory is divided into a number of static partitions at system generation time. Moreover, a process may be loaded into a partition of equal or greater size.

Partition size Two alternatives of fixed partition are as follows:

1. Equal-size partitions
2. Unequal-size partitions



Equal-size partitions: Any process whose size is less than or equal to the partition size can be loaded into any available partition.

Two problems with this technique are as follows:

1. A program may be too big to fit into a partition. Use overlaying to solve this problem.
2. Main memory utilization is extremely inefficient, as there is a possibility of internal fragmentation.

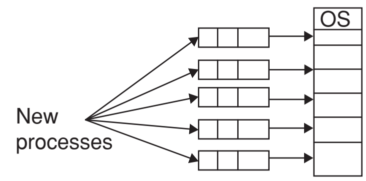
In *internal fragmentation*, there is a space wastage internal to a partition due to the fact that the block of data loaded is smaller than the partition.

Unequal-sized partition: Both the problems with equal-size partition can be lessened by using unequal-sized partitions.

Placement algorithm: With equal-size partitions, the placement of processes in memory is trivial. As all partitions are of equal size, it doesn't matter which partition is used.

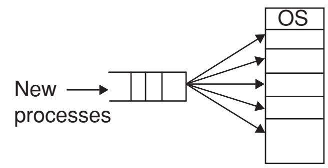
With Unequal-size partitions, there are two possible ways to assign processes to partitions:

1. Assign each process to the smallest partition within which it will fit.



- Figure shows one process queue for partition.
- Minimized internal fragmentation.
- Possibility of unused partitions.

2. Employ a single queue for all processes.



- When it is time to load a process into main memory, the smallest available partition that will hold the process is selected.

Advantages

1. Simple to implement.
2. Little OS overhead.

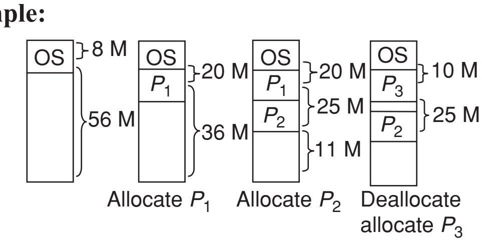
Disadvantages

1. Inefficient use of memory due to internal fragmentation.
2. Maximum number of active processes is fixed.

Dynamic Partitioning

With dynamic partitioning, the partitions are of variable length and number. When a process is brought into main memory, it is allocated exactly as much memory as it requires and no more.

Example:



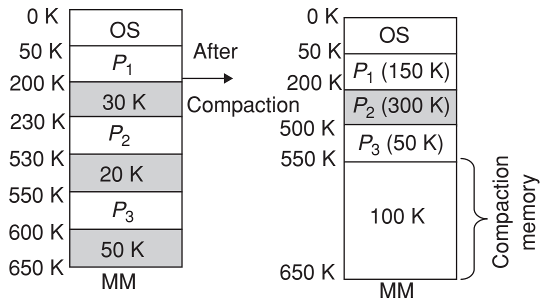
- This method starts out well, but eventually it leads to a situation in which there are a lot of small holes in memory.
- As time goes on, memory becomes more and more fragmented and memory utilization declines. This phenomenon is referred to as *external fragmentation*.

It indicates the memory that is external to all partitions becomes increasingly fragmented.

Compaction

Compaction is a technique by which the resident program are relocated in such a way that the small chunks of free

memory are made contiguous to each other and clubbed together into a single free partition that may be big enough to accommodate more programs.



It should be noted that compaction involves dynamic relocation of a program.

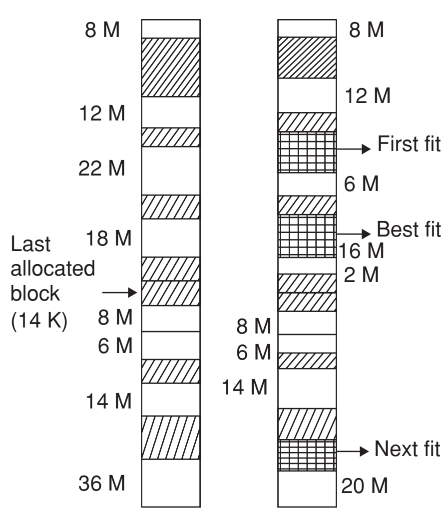
Placement algorithm

Memory compaction is a time-consuming process, and hence the OS uses some placement algorithms.

The three most common strategies to allocate free partitions to the new processes are as follows:

1. *First fit*: Allocate the first free partition, large enough to accommodate the process. IT executes faster.
2. *Best fit*: Allocate the smallest free partition that meets the requirement of the process. It achieves higher utilization of memory by searching smallest free partition.
3. *Worst fit*: Allocate the largest available partition to the newly entered process in the system.
4. *Next fit*: Start from current location in the list.

Example: Consider the following memory configuration after a number of placement and swapping out operations. The last block that was used was a 22 MB block from which a 14 MB partition was created. The figure (b) shows 16 MB allocation request.



(a) Before allocation (b) After allocation

Allocated block
Free block
Possible new allocation

Advantages of dynamic partitioning

1. Memory utilization is generally better as partitions are created dynamically.
2. No internal fragmentation as partitions are changed dynamically.
3. The process of merging adjacent holes to form a single larger hole is called coalescing.

Disadvantages

1. Lots of OS space, time, complex memory management algorithms are required.
2. Compaction time is very high.

Buddy system: Both fixed and dynamic partitioning schemes have drawbacks.

In Buddy system, memory blocks are available of size 2^K words, $L \le K \le U$, where,

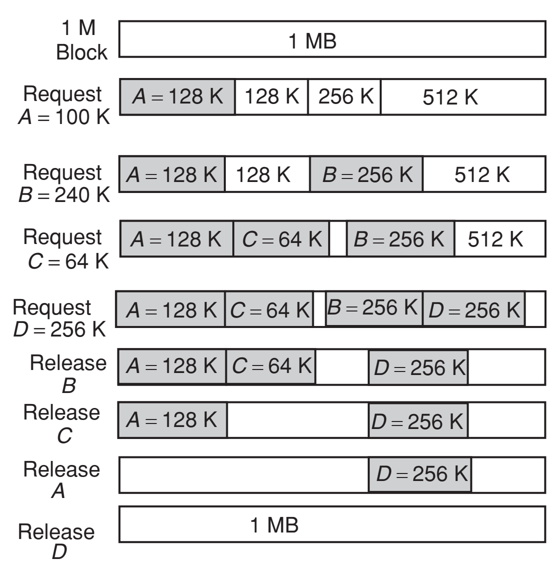
2^L = Smallest-size block that is allocated.

2^U = Largest-size block that is allocated.

Generally, 2^U is the size of the entire memory available for allocation. If a request of size 'S' such that $2^{U-1} < S \le 2^U$ is made, then the entire block is allocated. Otherwise the block is split into two equal buddies of size 2^{U-1}. If $2^{U-2} < S \le 2^{U-1}$, then the request is allocated to one of the two buddies. Otherwise, one of the buddies is split in half again. This process continues until the smallest block greater than or equal to 'S' is generated and allocated to the request.

1. At any time, the buddy system maintains a list of holes of each size 2^i.
2. A hole may be removed from the $(i + 1)$ list by splitting it in half to create two buddies of size 2^i in the 'i' list.
3. Whenever a pair of buddies on the i list both become unallocated, they are removed from the list and coalesced into a single block on the $(i + 1)$ list.

Example:



Non-contiguous Storage Allocation Methods

Paging

In simple paging, the main memory is divided into a number of equal-size frames. Each process is divided into a number of equal-size frames. The chunks of processes are referred as *pages*. A process is loaded by loading all of its pages into available, not necessarily contiguous frames.

Example: At a point in time, some of the frames in memory are in use and some are free. A list of free frames is maintained by the OS.

Consider four processes with their pages as displayed below:

Process P	Process Q	Process R	Process S
P.0	Q.0	R.0	S.0
P.1	Q.1	R.1	S.1
P.2	Q.2	R.2	S.2
P.3		R.3	S.3
			S.4

Let the main memory consist of 15 frames:
Main memory

		Load P
0		P.0
1		P.1
2		P.2
3		P.3

14				

1. The OS maintains a page table for each process.
2. The page table shows the frame location for each page of the process.
3. Within a program, each logical address consists of a page number and an offset with in the page.
4. Here a logical address is the location of a word relative to the beginning of the program; the processor translates that into a physical address.
5. For this, the processor must know the following details:

- *Logical address:* Consists page number and offset.
- *Page table:* Used to produce physical address (Frame number, offset).

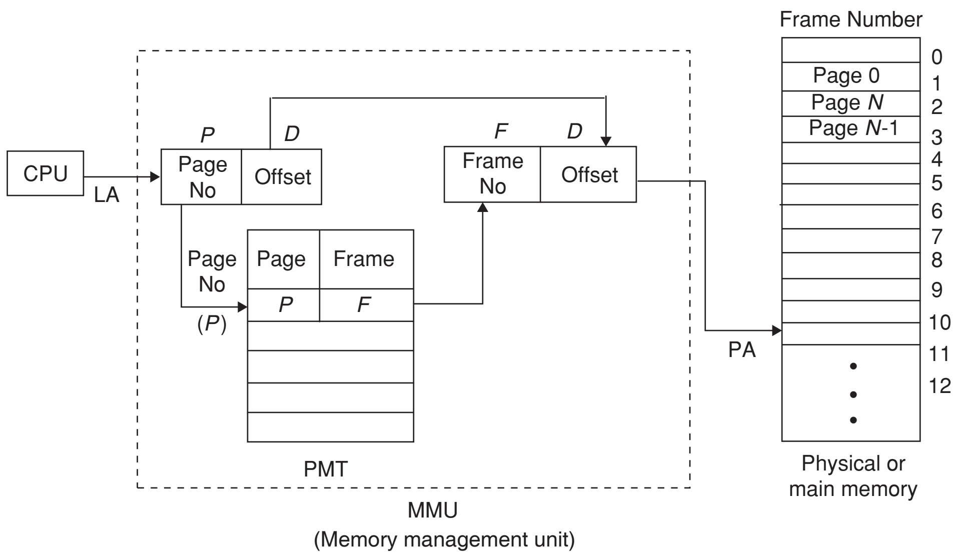
In the previous example, the page tables of each process will be:

	Process P page table	Process Q page table	Process R page table
0	0	–	7
1	1	–	8
2	2	–	9
3	3		10

	Process S page table
0	4
1	5
2	6
3	11
4	12

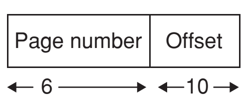
Free frame list.
13
14

Address mapping in paging



Example: Let 16-bit address is used by the processor and the page size is 1 KB.

Then number of pages in main memory $= \frac{2^{16}}{2^{10}} = 2^6$.
∴ Page number = 6-bits
Offset = 10-bits



For the relative address 1502 =
0000010111011110
The page number = 000001 = 1
and offset = 0111011110 = 478, that is, the physical location will be an offset $(478)_{10}$ on page 1.

Let the page 1 is present in frame 6. Then the physical address will be 0001100111011110.

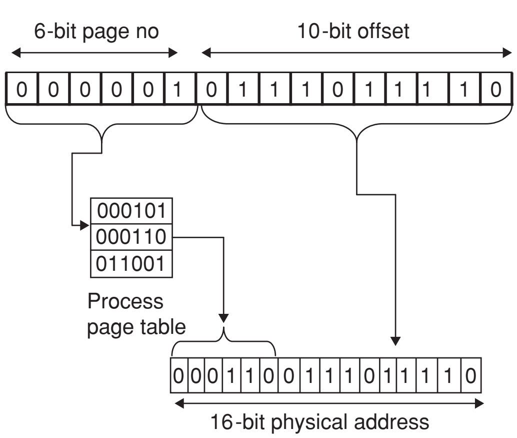


Figure 2 Paging.

Steps for address translation

1. Extract the page number from the logical address.
2. Use the page number as an index into the process page table to find the frame number.
3. The physical address will be constructed by appending the frame number to the offset.

Advantage

There is no external fragmentation.

Disadvantage

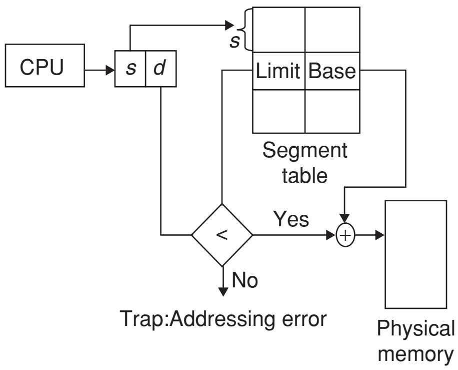
There is a small amount of internal fragmentation.

Segmentation

1. Each process is divided into a number of unequal-size segments.
2. A process is loaded by loading all of its segments into dynamic partitions that need not be contiguous.
3. The logical address using segmentation consists of two parts: *segment number* and an *offset*.
4. The principle inconvenience of segmentation is that the programmer must be aware of the maximum segment size limitation.
5. It makes use of a segment table for each process and a list of free blocks of main memory.
6. Each segment table entry would have to give the starting address in main memory of the corresponding segment. It also contains the length of the segment.
7. Steps for address translation:
   - Extract the segment number from the logical address.
   - Use the segment number as an index into the process segment table to find the starting physical address of the segment.

- Compare the offset to the length of the segment. If the offset is greater than or equal to the length, the address is invalid.
- The desired physical address is the sum of the starting physical address of the segment plus the offset.

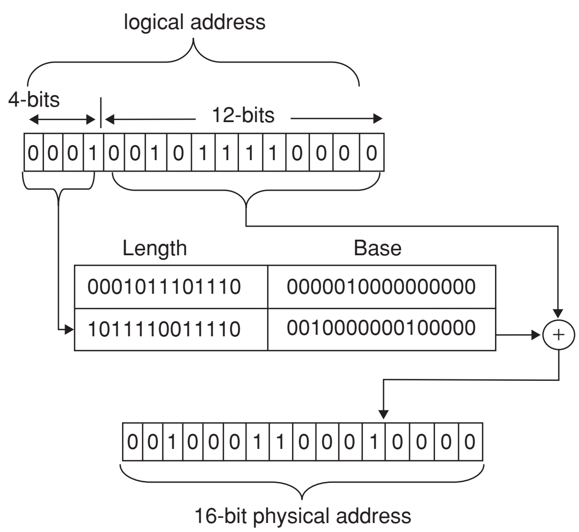
Hardware support for segmentation



Example: Consider the logical address 0001001011110000.

Let the segment number consists of 4-bits. Then segment number = 0001 = 1

Offset = 001011110000 = 752.



Advantages

1. No internal fragmentation
2. Improved memory utilization.
3. Reduced overhead compared to dynamic partitioning.

Disadvantage

1. External fragmentation.

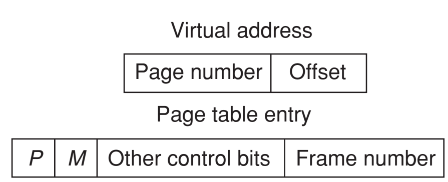
Virtual Memory

1. In simple paging/segmentation, it is not necessary that all of the pages or all of the segments of a process be in main memory during execution.
2. Suppose that it is time to bring new process into memory. The OS begins by bringing in only one or a few pages to include the initial program page and initial data page to which those instructions refer.
3. The portion of a process that is actually in main memory at any time is defined to be the resident set of the process.
4. If the processor encounters a logical address that is not in main memory, it generates an interrupt indicating a memory access fault.
5. Then the OS brings the required page to the main memory.
6. With virtual memory,
   - More processes may be maintained in main memory.
   - A process may be larger than all of main memory, then also it will be executed.
7. Virtual memory is a storage allocation scheme in which secondary memory can be addressed as though it were part of main memory.
8. ***Thrashing:*** When the OS brings one page in, it must throw another out. If it throws out a page just before it is used, then it will just have to go get that piece again almost immediately. Too much of this leads to a condition known as *thrashing*.

   If the system spends most of its time in swapping rather than executing instructions then that situation refers to thrashing.
9. Principle of locality suggests that a virtual memory scheme may work.
10. Virtual memory will be practical and effective if
    - There is a hardware support for paging/segmentation.
    - The OS includes software for managing the movement of pages/segments.

Paging with Virtual Memory

1. The main difference between paging and virtual memory paging is that in virtual memory paging concept, not all pages of a process need to be in main memory frames for the process to run. Pages may be read in as needed.
2. A page table is also needed for a virtual memory scheme based on paging. Also it is typical to associate a unique page table with each process.
3. The virtual address and page table entries for virtual memory paging are shown below:



P: Present bit. This bit specifies whether that particular page is present in main memory or not.

M: Modified bit. This bit indicates whether the contents of the corresponding page have been altered since the page was last loaded into main memory.

Page table structure

1. To read a word from memory, translate the virtual or logical address consisting of page number and offset into physical address consisting of frame number and offset, using a page table.
2. Page table must be stored in main memory to access it.

Hardware implementation for virtual memory paging

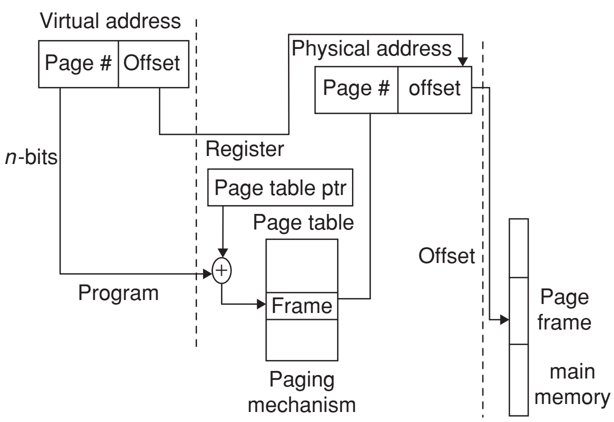


Figure 3 Address translation in paging system.

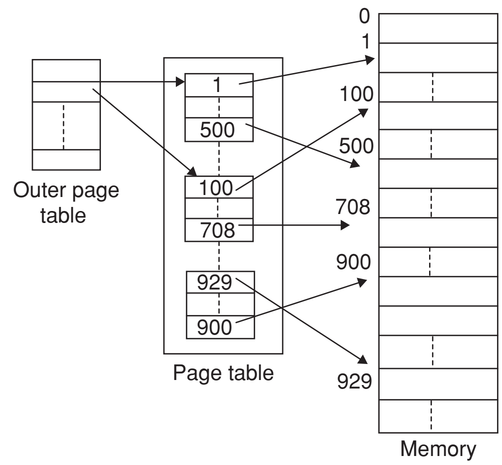
1. The amount of memory used by the page tables could be high.
2. To overcome this problem, most virtual memory schemes store page tables in virtual memory rather than real memory, that is, page tables are subject to paging just as other pages are.
3. When a process is running, at least a part of its page table must be in main memory, including the page table entry of the currently executing page.
4. Some processors make use of a two-level scheme to organize large page tables.

Hierarchical page table

1. If page table size is large, then use hierarchical page table.
2. The logical address space is broken up into multiple page tables.

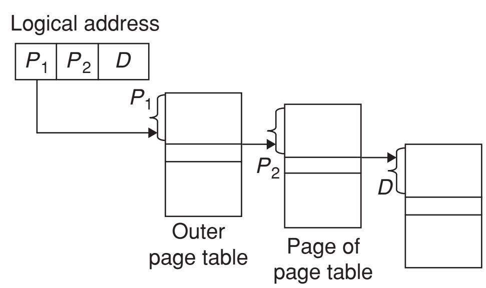


A logical address space (on 32-bit machine with 1 K page size) is divided into a page number consisting of 22-bits, page offset consisting of 10-bits. The page number is paged, the page number is divided into 12-bit page number and 10-bit page offset.

Page number		Page offset
P_1	P_2	D
12	10	10

Here, P_1 is an index into the outer page table, P_2 is the displacement within the page of the outer page table.

Address translation (diagrammatic)



Drawback: Page table size is proportional to that of the virtual address space.

Inverted page table

1. Here, the page number portion of a virtual address is mapped into a hash value, using simple hash function.
2. The hash value is a pointer to the inverted page table, which contains the page table entries.
3. There is one entry in the inverted page table for each real memory page frame rather than one per virtual page.
4. Thus, a fixed proportion of real memory is required for the tables.
5. One virtual address may map into the same hash table entry, so a chaining technique is used for managing the overflow.
6. The page table's structure is called *inverted*, because it indexes page table entries by frame number rather than by virtual page number.

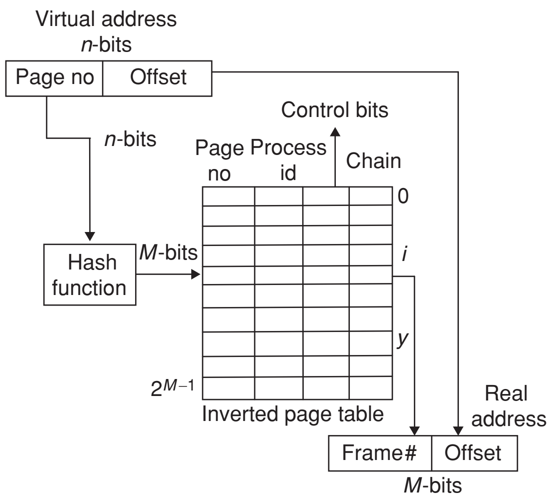


Figure 4 Inverted page table structure.

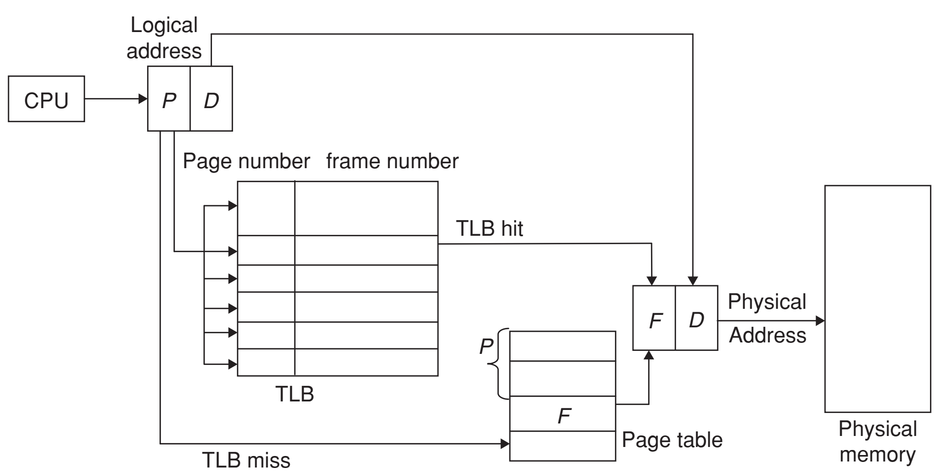
Translation look-a-side buffer (TLB)

1. The straight-forward virtual memory scheme would have the effect of doubling the memory access time.
2. To overcome this problem, most virtual memory schemes make use of a special high speed cache for page table entries, usually called TLB.
3. TLB contains the page table entries that have been most recently used.

Paging hardware with TLB

1. Given a virtual address, the processor will first examine the TLB. If the desired page table entry is present, that is, TLB hit, then the frame number is retrieved and real address is formed.
2. If there is a TLB miss, the processor uses the page number to index the process page table and examine the corresponding page table entry.
3. If present bit is set, then the page is in main memory and the processor can retrieve the frame number from the page table entry to form the real address.
4. The processor also updates the TLB to include this new page table entry.
5. If the page is not in main memory, then page fault is issued.
6. Then the OS will load the needed page and updates the page table.



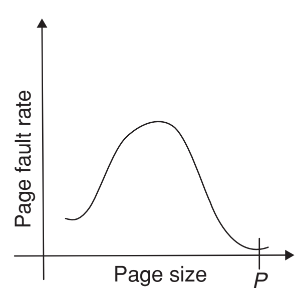
Organization of TLB

1. Each entry in TLB must include the page number and the complete page table entry.
2. The TLB may organized its entries either in
   - Direct mapping
   - Associative Mapping
3. The hardware must also consider the ways in which entries are organized and which entry to replace.

Note: The virtual memory mechanism must interact with the main memory cache system also.

Page size The factors to be considered for page size are as follows:

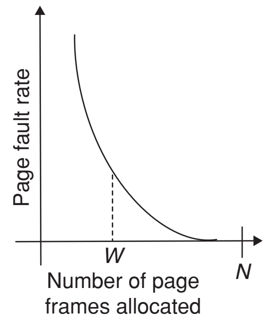
1. If page size is smaller: Then internal fragmentation is less. But it results in larger page tables. For large programs, the page fault rate increases.
2. Rotational secondary devices favour a larger page size for more efficient block transfer.



where P = size of entire process.

The above figure shows the relationship between page size and page fault rate.

The page fault rate is also determined by the number of frames allocated to a process. This relation is shown below.



where W = working set size
N = Total number of pages in process

Note: The design issue of page size is related to the size of physical main memory and program size.

Advantages of virtual memory paging

1. No external fragmentation
2. Higher degree of multiprogramming
3. Large virtual address space

Disadvantage

Overhead of complex memory management.

Segmentation with Virtual Memory

1. Memory consists of multiple segments.
2. Segments are of unequal and dynamic in size.
3. It simplifies the handling of growing data structures.
4. It allows programs to be altered and recompiled independently.
5. It lends itself to sharing among processes.
6. It lends itself to protection.
7. A unique segment table is associated with each process.
8. The virtual address and segment table entries are as shown below:

Virtual address

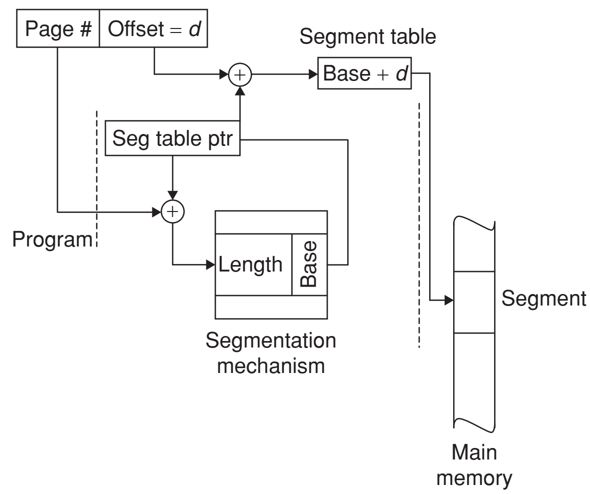
Segment number	Offset

Segment table entry

P	M	Other control bits	Length	Segment base

9. Only some of the segments of a process may be in main memory. To identify which segment is present in the main memory, use present bit P.
10. To know whether the segment is modified or not, use M-bit.

Address translation in a segmentation system (using virtual memory)



Advantages

1. No internal fragmentation
2. Higher degree of multiprogramming
3. Large virtual address space.
4. Protection and sharing support.

Disadvantage

1. Overhead of complex memory management.

Combined paging and segmentation

1. Here, the users address space is broken up into a number of segments by the programmer.
2. Each segment is, in turn, broken up into a number of fixed size pages, which are equal in length to a main memory frame.
3. If a segment has length less than that of a page, the segment occupies just one page.
4. The virtual address, segment table and page table entries are as shown below:

Virtual address

Segment number	Page number	Offset

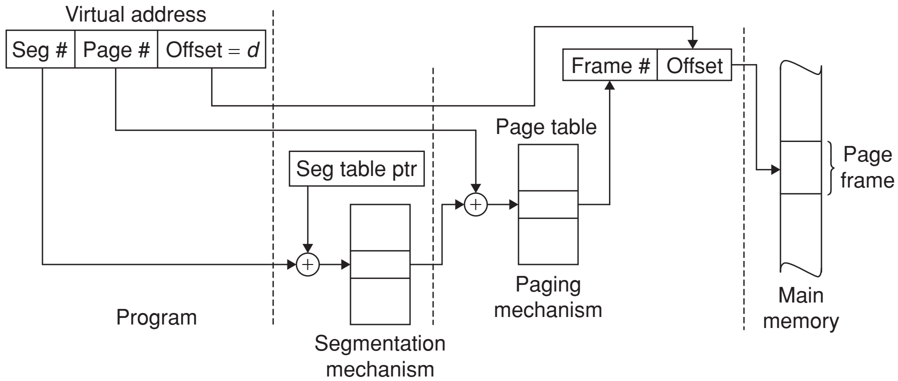
Segment table entry

Control bits	Length	Segment base

Page table entry

P	M	Other control bits	Frame number

Structure of combined segmentation/paging system



Notes:

1. Segmentation lends itself to the implementation of protection and sharing policies.
2. To achieve sharing, it is possible for a segment to be referenced in the segment tables of more than one process.

OS Software for Memory Management

We consider the following software policies for virtual memory:

1. Fetch policy:
   - Demand
   - Prepaging
2. Placement policy
3. Replacement policy:
   - Optimal
   - LRU
   - FIFO
   - Clock
4. Resident set management
   - Resident set size
   I. Fixed
   II. Variable
   - Replacement scope
   I. Local
   II. Global
5. Cleaning policy
   - Demand
   - Pre-cleaning
6. Load control
   - Degree of multi-programming

Fetch policy Determines when a page should be brought into main memory.

1. ***Demand paging:*** Here a page is brought into main memory only when a reference is made to a location on that page.
2. ***Prepaging:*** It is a technique that reduces the large number of page faults at process start up.
   - Prepaging is used to get before all or some of the pages a process will need, before they are referenced.
   - If prepaged pages are unused, I/O and memory would be wasted.
   - Assume 's' pages are prepaged and α of the pages are used.
   - Cost of $(s * \alpha)$ to save page faults greater or less than the cost of prepaging $s \times (1 - \alpha)$ unnecessary page. If α near zero $\Rightarrow$ prepaging is lost.

Placement Policy

1. Determines where in real memory a process piece is to reside.
2. In pure segmentation system, the policies like best fit, first fit, etc., are used.
3. For a system that uses either pure paging or paging combined with segmentation, placement is usually irrelevant.

Replacement policy This deals with the selection of a page in main memory to be replaced when a new page must be brought in. In a replacement policy, we have to consider the following:

1. How many page frames are to be allocated to each active process.
2. Whether the set of pages to be considered for replacement should be limited to those of the process that caused the page fault or encompass all the page frames in main memory.
3. Among the set of pages considered, which particular page should be selected for replacement.

Page Fault

1. Whenever a processor needs to execute a particular page and that page is not available in main memory, this situation is said to be *page fault*.

2. When the page fault occurs, the page replacement will be done.
3. 'Page Replacement' means select a victim page in the main memory, replace that page with the required page from the backing store (disk).
4. Some of the replacement algorithms are as follows:
   - FIFO
   - Optimal
   - LRU
   - Clock

FIFO (First-in-First-Out Algorithm)

1. Replace a page that is the oldest page of all the pages of the main memory.
2. Focuses on the length of time a page has been in memory rather than how much the page is being used.

Example:
Consider the reference string: 0 1 2 3 0 1 2 3 0 1 2 3 1

0	1	2	3	0	1
F	*F*	*F*	*F*	*F*	*F*
0	0	0	3	3	3
		1	1	0	0
		2	2	2	1

2	3	0	1	2	3	1
F	*F*	*F*	*F*	*F*	*F*	*H*
2	2	2	1	1	1	1*
0	3	3	3	2	2	2
1	1	0	0	0	3	3

Here the symbol '*F*' indicates page fault.

The number of page faults = 12

'*H*' indicates the page is already in the memory. The remaining pages are not present in memory that is why page fault occurs. In general, the more frames there are, the less page fault.

$$\text{Page fault rate} = \frac{\text{Number of page faults}}{\text{Number of bits in reference string}}$$

$$= \frac{12}{13} = 0.923 = 92.3\%.$$

Belady's Anomaly

Example: Consider the reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5

Number of frames = 4

F	*F*	*F*	*F*	*H*	*H*
1	1	1	1	1	1
	2	2	2	2	2
		3	3	3	3
			4	4	4
1	2	3	4	1	2

F	*F*	*F*	*F*	*F*	*F*
5	5	5	5	4	4
2	1	1	1	1	5
3	3	2	2	2	2
4	4	4	3	3	3
5	1	2	3	4	5

The number of page faults = 10

Consider the same reference string with three frames.

1	2	3	4	1	2
F	*F*	*F*	*F*	*F*	*F*
1	1	1	4	4	4
	2	2	2	1	1
		3	3	3	2

5	1	2	3	4	5
F	*H*	*H*	*F*	*F*	*H*
5	5	5	5	5	5
1	1	1	3	3	3
2	2	2	2	4	4

Here number of page faults = 9

Here, as the number of frames increases the page fault also increases. This is known as *Belady's anomaly*.

Optimal page replacement algorithm

1. Replace the page that will not be used for the longest period of time.

   Example: Consider the reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5 using four frames.

F	*F*	*F*	*F*	*H*	*H*
1	1	1	1	1	1
	2	2	2	2	2
		3	3	3	3
			4	4	4
1	2	3	4	1	2

F	*H*	*H*	*H*	*F*	*H*
1	1	1	1	4	4
2	2	2	2	2	2
3	3	3	3	3	3
5	5	5	5	5	5
5	1	2	3	4	5

Number of page faults = 6

Disadvantage

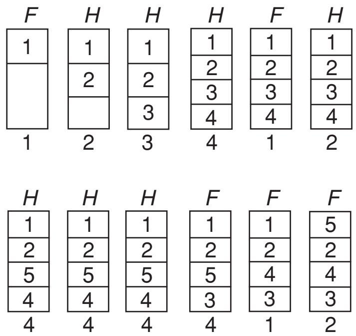
It requires future knowledge of reference string, so used for comparison studies.

LRU (least recently used) algorithm

1. Replace a page that has not been used for the longest period of time.
2. It looks backward in time rather than forward.
3. It associates with each page the time of that page last used.
4. Two methods of implementation:
   - Counters
   - Stack

   Example: Consider reference String: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5

Number of frames = 4



Number of page faults = 8 (less than FIFO)

Approach to Implement LRU Replacement

LRU is a good page replacement policy, but the problem with these is how to determine the frame used for the last time.

This is implemented by using two approaches:

1. Using counters
2. Using stacks

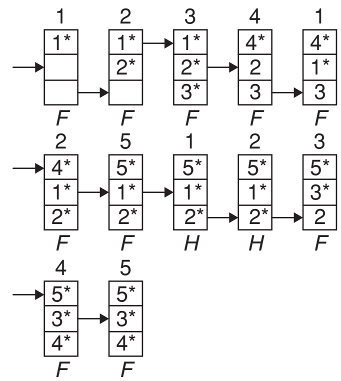
Using counters, LRU is implemented as follows: Every page entry has a counter, whenever a page is referenced, the clock value is copied into the counter. If the page has to be replaced, then it refers to the look up of the counter, whichever is having oldest time that is changed.

Using stack, LRU is implemented as follows: Form a doubly linked list of page numbers and keep it in stack whenever a page is referenced it is moved to the top of the stack that is top of the stack contains recently referenced page. Bottom of the stack will have least recently used one.

Clock replacement algorithm

1. The simplest form of clock policy requires the association of an additional bit with each frame, referred to as the use bit.
2. When a page is first loaded into frame in memory, the use bit for that frame is set to 1.
3. Whenever the page is subsequently referenced, its use bit is set to 1.
4. The set of frames that are candidates for replacement is considered to be a circular buffer, with which a pointer is associated.
5. When a page is replaced, the pointer is set to indicate the next frame in the buffer after the one just updated.
6. When it comes time to replace a page, the OS scans the buffer to find a frame with a use bit set to 0.
7. Each time it encounters a frame with a use bit of 1, it resets that bit to 0 and continues on.
8. If any of the frames in the buffer have a use bit of 0 at the beginning of this process, the first such frame encountered is chosen for replacement.
9. If all of the frames have a use bit of 1, then the pointer will make one complete cycle through the buffer, setting all the use bits to 0 and stop at its original position, replacing the page in that frame.

Example: Consider the reference string 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5, with three main memory frames:



∴ Number of misses = 9

Note: The clock algorithm was approximately closer in performance to LRU.

Effective memory access time

The percentage of times a page number is found in the associative registers is called the *hit ratio*. If we fail to find the page number in the associative registers, then we must first access memory for the page table and frame number, and then access the required byte in memory. To find the effective access time, we should weigh each case by its probability.

EMAT: Is given as $= p * s + (1 - p) * m$.

Where

p = Page fault rate

s = Page fault service time

m = Main memory access time

$(1 - p)$ = page hit ratio.

Frame locking Some of the frames in main memory may be locked. When a frame is locked, the page currently stored in that frame may not be replaced.

Page buffering To improve performance, a replaced page is not lost but rather is assigned to one of two lists:

1. The free page list if the page has not been modified or
2. The modified page list if it has modified.

Resident set management

Resident set size The OS must decide how many pages to bring in, that is, how much main memory to allocate to a particular process. Two policies are there:

1. Fixed allocation
2. Variable allocation

Fixed allocation This policy gives to a process a fixed number of frames in main memory within which to execute.

Variable allocation This policy allows the number of page frames allocated to a process to be varied over the life time of the process.

Replacement scope This is of two types as follows:

Local page replacement: When a process requests for a new page to be brought in and there are no free frames in the memory, we choose a frame allocated to only that process for replacement.

Global replacement: It allows a process to select a replacement frame from the set of all frames, even if that frame is currently allocated to some other processes. So, one process can take a frame from another.

Fixed allocation, local replacement

1. Number of frames allocated to a process is fixed.
2. Page to be replaced is chosen from among the frames allocated to that process.

Variable allocation, global scope

1. Page to be replaced is chosen from all available frames in main memory.
2. Size of resident set of processes varies.

Variable allocation, local scope

1. The number of frames allocated to a process may be changed from time to time.
2. Page to be replaced is chosen from among the frames allocated to that process.

Working set: This strategy is used to determine the resident set size and the timing of changes.

The working set with parameter Δ for a process at virtual time t, which we designated as $W(t, \Delta)$, is the set of pages of that process that have been referenced in the last Δ virtual time units.

Virtual time: Consider a sequence of memory references, $r(1)$, $r(2)$, … in which $r(i)$ is the page that contains the ith virtual address generated by a given process.

Time is measured in memory references; thus, $t = 1, 2, 3, \ldots$ measures the processes internal virtual time.

The variable 'Δ' is a window of virtual time over which the process is observed.

The working set size will be a non-decreasing function of the window size.

$$W(t, \Delta + 1) \supseteq W(t, \Delta).$$

For the sequence of page references 24, 15, 18, 23, 17, 15, 24, 18, 17, 17, 15. And window size = 2 then working set will be

{24, {24, 15,}, {15, 18}, {18, 23}, {23, 24}, {24, 17}, {17, 18}, {18, 24}, {18, 24}, {18, 17}, {17}, {17, 15}}

Page fault frequency (PFF) algorithm

1. The algorithm requires a use bit to be associated with each page in memory.
2. The bit is set to 1, when that page is accessed.
3. When a page fault occurs, the OS notes the virtual time since the last page fault for the process.
4. A threshold F is defined. If the amount of time since the last page fault is less than F, then a page added to resident set of the process.
5. Otherwise, discard all pages with a use bit of 0 and shrink the resident set according.

Note: PFF does not perform well during the transient periods when there is a shift to a new locality.

Variable interval sampled working set (VSWS)

1. The VSWS policy evaluates the working set of a process at sampling instances based on elapsed virtual time.
2. VSWS considers three parameters:
   M: The minimum duration of sampling interval
   L: The maximum duration of sampling interval
   Q: The number of page faults that are allowed to occur between sampling instances.
3. The policy works as following:
   - If virtual time since the last sampling instance reaches L, then suspend the process and scan the use bits.
   - If, prior to an elapsed virtual time of L, Q page faults occur,
     I. If the virtual time since the last sampling instance is less than M, then wait until the elapsed virtual time reaches M to suspend the process and scan the use bits.
     II. If the virtual time since the last sampling instance is greater than or equal to M, suspend the process and scan the use bits.

Cleaning policy It determines when a modified page should be written out to secondary memory. Two approaches are as follows:

1. Demand cleaning
2. Pre-cleaning

Demand cleaning A page is written out to secondary memory only when it has been selected for replacement.

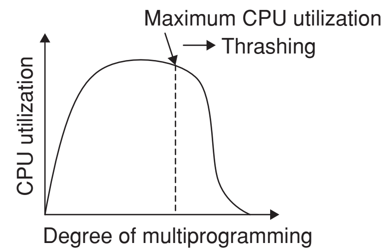
Pre-cleaning This policy writes modified pages before their page frames are needed so that pages can be written out in batches.

Load control It is concerned with determininig the number of processes that will be resident in main memory, which has been referred to as the multiprogramming level.

If too few processes are resident at any one time, it leads to swapping. If too many processes are present, thrashing will occur.

Cause of thrashing Consider the following scenario:

The OS monitors CPU utilization. If the utilization is too low, we increase the degree of multiprogramming by introducing a new process to the system. A global page replacement algorithm is used, which replaces pages with no regard to the process to which they belong. Now, say that a process enters a new phase in its execution and needs more frames. It starts faulting and taking frames away from other processes. These processes need those pages, however and so they also fault, taking frames from other processes. These faulting processes must use the paging device to swap pages in and out. As they queue up for paging device, the ready queue empties. As processes wait, for the paging device, CPU utilization decreases the CPU scheduler sees the decreasing CPU utilization; so it increases the degree of multiprogramming. The new process tries to get started by taking frames from running processes, causing more page faults, and a longer queue for paging device. As a result, CPU utilization drops even, further. The CPU scheduler tries to increase the degree of multiprogramming even more. Thrashing occurs, and the system throughput plunges. The page fault rate (FT) increases tremendously. Effective memory access time increases. No work is getting done because the processes are spending all their time in paging.



Thrashing

Exercises

Practice Problems 1

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider a 3-level memory hierarchy shown in the following table, with access times to memory:

Hierarchy level	Cache hit ratio	Page transfer time
M_1	0.55	0.003 ms
M_2	0.92	0.3 ms
M_3	–	1.0 ms

When a miss occurs, data is fetched from the next level. Calculate the average time required for a process to read one word from the memory system.

(A) 0.379 (B) 0.162
(C) 0.2798 (D) 0.172

2. Consider a memory system with FIFO page replacement algorithm policy. For an arbitrary page access pattern, increasing the number of page frames in main memory will

(A) Always decrease the number of page faults
(B) Always increase the number of page faults
(C) Sometimes increase the number of page faults
(D) Never effect the number of page faults

3. Consider the below page address stream generated by executing a program:

4 5 4 3 7 4

Assuming that LRU is used for page replacement and at most three frames are available in the memory for the process, find the number of page faults that can occur (initially all frames empty).

(A) 0 (B) 1
(C) 3 (D) 4

4. Consider a logical address space of four pages of 2048 words each mapped into a physical memory of 32 frames. How many bits in logical address?

(A) 12-bits (B) 14-bits
(C) 13-bits (D) 11-bits

5. The time taken to service a page fault is on average 10 ms and the memory access time is 20 μs. If the hit ratio is 70%, calculate the average access time.

(A) 3018 μs (B) 4014 μs
(C) 3014 μs (D) 4024 μs

6. Consider the following page trace:

4, 3, 2, 1, 4, 3, 5, 4, 3, 2, 1, 5

Number of frames for the Job $M = 4$. Then the page fault ratio using FIFO technique will be

(A) 63% (B) 75%
(C) 83% (D) 94%

7. The available main memory for loading pages is 64 MB with a frame size of 8 MB. If pages of size 6 MB, and 4 MB are loaded into memory, what is the percentage of the internal fragmentation resulted?

(A) 42.5 (B) 37.5
(C) 57.5 (D) 62.45

8. A demand paging system takes 50 time units to handle a page fault and 200 time units to replace a dirty page. Access time of memory is 2 time units. Probability of page fault and dirty page is P. Average access time is 4 time units. Then what is the value of P?

(A) 0.037 (B) 0.027
(C) 0.012 (D) 0.042

9. Assume that a total memory 20 KB is available with no partition. If Buddy system technique is used and there are total of four partitions to serve the request, the closest range of the requested size is

(A) 12.5 and 25 (B) 14.5 and 30
(C) 15.5 and 25 (D) 14.5 and 40

10. A system uses FIFO page replacement algorithm. It has three page frames with no pages loaded. First 50 pages are accessed in some order and the same pages are accessed in the reverse order. What is the number of page faults?
(A) 98 (B) 96
(C) 97 (D) 95

11. If 32-bit addressing is used for pages whose maximum size is 512 KB, what is the maximum number of pages that can be addressed?
(A) 4096 (B) 2048
(C) 8192 (D) 16384

12. Calculate the overhead due to page table if given the average process in bytes is 16-bytes, the page size is 32-bytes and the page entry is 2-bytes.
(A) 15 (B) 17
(C) 18 (D) 19

13. In a system with 32-bit virtual address and 1 KB page size, use of one-level page tables for virtual to physical address translation is not practical because of
(A) The large amount of internal fragmentation
(B) The large amount of external fragmentation
(C) The large memory overhead in maintaining page tables
(D) The large computation overhead in the translation process

14. If an instruction takes time 10 m sec if there is no page fault and time 20 m sec if there is a page fault, what is the effective instruction time if page fault occurs once every 5 instructions?
(A) 12.5 msec (B) 12 msec
(C) 14 msec (D) 15 msec

15. Let an instruction take 10 ms and page fault takes an additional 5 ms. If the average page fault occurs after 20 instructions, the effective instruction time will be
(A) 10 ms (B) 10.25 ms
(C) 0.25 ms (D) 10.75 ms

16. A 0.8 MB-sized memory is managed using variable partitions, while the rest of the memory is occupied by a 0.26 MB partition, 0.27 MB partition and 0.25 MB partitions in the order. Best-fit strategy is being adopted where would be a 0.18 MB allocation request is fulfilled?
(A) 0.26
(B) 0.27
(C) 0.25
(D) Request will be denied

Common data for questions 17 and 18: Suppose that the OS uses variable length partitions for memory management. At some particular time, the running process occupies a partition between physical addresses 20,000 and 40,000.

17. The values of base and limit register are respectively
(A) 20, 000, 40,000
(B) 20,000, 20,000
(C) 0, 10,000
(D) 0, 40,000

18. What physical address corresponds to a virtual address of 13,000?
(A) 13,000
(B) 43,000
(C) 33,000
(D) Out of range

19. Consider a page table where translation look ahead buffer is used. TLB hit ratio is 0.95 and generally takes 1 nanosecond to retrieve the frame number. If a miss is recorded by the TLB then an additional overhead of 10 nanoseconds should be taken into consideration, further cache and main memory reference takes 100 ns on average, what is the average memory fetch time using the TLB? Assume main memory accesses are always a success.
(A) 101 ns (B) 105 ns
(C) 200 ns (D) 205 ns

20. Consider a 1 MB process which is divided into five segments. Each segment is further divided into pages whose size is 4 KB. What is the maximum segments possible? Assume that the system is byte addressable.
(A) 64 (B) 128
(C) 256 (D) 512

Practice Problems 2

Directions for questions 1 to 20: Select the correct alternative from the given choices.

1. Consider a logical address space of 32 pages of 2048 words mapped into memory of 64 frames. Then the number of bits required for logical address are
(A) 16-bits (B) 17-bits
(C) 18-bits (D) 20-bits

2. In which of the page table techniques the logical address space is broken into multiple page table?
(A) Inverted Page Table
(B) Hierarchical Page Table
(C) Hashed Page Table
(D) None of the above

3. Consider a system with 70% hit ratio, 60 nanoseconds time to search the associative registers, 800 nanoseconds to access memory. What is the effective memory access time?
(A) 1200 nsec (B) 1100 nsec
(C) 1300 nsec (D) 2200 nsec

4. On a system using fixed partitions, all of size 2^8, the number of bits used by the limit register is
   (A) 128 (B) 256
   (C) 8 (D) 1024

5. Working set (t, k) at an instant of time, t, is the set of
   (A) k future references that the operating system will make
   (B) future references that the operating system will make in the next 'k' time units
   (C) k references with high frequency
   (D) pages that have been referenced in the last k time units.

6. Cache and interleaved memories are ways of speeding up memory access between CPUs and slower RAM. Which of the following memory models are best suited (i.e., improves performance the most) for which programs?
   (i) Cached memory is best suited for small loops.
   (ii) Interleaved memory is best suited for small loops.
   (iii) Interleaved memory is best suited for large loops.
   (iv) Cache memory is best suited for large sequential code.
   (A) (i) and (ii) are true
   (B) (i) and (iii) are true
   (C) (iv) and (ii) are true
   (D) (iv) and (iii) are true

7. A paging system with a page table in memory every reference to memory takes 100 ns. The TLB hit ratio is 85% and the time needed for searching TLB is almost negligible. What is the effective memory access time?
   (A) 115 ns (B) 135 ns
   (C) 145 ns (D) 125 ns

8. Consider the page sequence 4, 2, 1, 5, 3, 2, 1, 5, 0, 2, 5. If FIFO page replacement algorithm is used and frame size is 3, then the percentage of page fault is
   (A) 99% (B) 90.9%
   (C) 80.8% (D) 89.9%

9. If the page size is 32 KB, primary page table contains 4096 entries and the secondary page table contains 256 entries, then what is the size of logical address in bits?
   (A) 15-bits (B) 20-bits
   (C) 32-bits (D) 35-bits

10. If page size is 2 KB and logical address is 20-bit, then the number of entries in the page table is
    (A) 2048 B (B) 256 B
    (C) 512 B (D) 1 MB

11. Consider a paging system with the page table stored in memory. If a memory reference takes 200 ns, how long does a paged memory reference take?
    (A) 100 ns (B) 200 ns
    (C) 300 ns (D) 400 ns

12. Consider a logical address space of eight pages of 1024 words each mapped onto a physical memory of 32 frames. How many bits are there in the logical address and in the physical address?
    (A) 10, 18 (B) 13, 18
    (C) 13, 15 (D) 10, 5

13. For a paged system, TLB hit ratio is 0.9. Let the RAM access time 't' be 20 ns and the TLB access time 'T' be 100 ns. Then effective memory access (with TLB) will be
    (A) 120 ns (B) 200 ns
    (C) 130 ns (D) 150 ns

14. Assume that a user program is 100 K words and secondary storage device is a fixed hard disk with an average latency of 8 ms and a transfer rate of 2,50,000 words/second. Then find the swap time of a transfer of 100 K words to or from memory.
    (A) 816 ms (B) 408 ms
    (C) 204 ms (D) 8 ms

15. Consider the following segment table:

Segment	Limit	Base
0	1000	1400
1	400	6300
2	400	4300
3	1100	3200
4	1000	4700

    The physical address for a logical address which is in segment 2 with offset 253 is
    (A) 4553 (B) 6353
    (C) 6253 (D) 4453

16. Consider a process of size 2 MB. If the page size is 0.5 KB, what is the size of the page table (assuming that each page is mapped by a 32-bit size page table entry)?
    (A) 8 KB (B) 16 KB
    (C) 24 KB (D) 32 MB

17. A CPU generates 32-bit virtual address. The page size is 2 KB. The translation look-aside buffer (TLB) which can hold 256 page table entries and is two-way set associative mapping. The number of bits in the TLB tag is
    (A) 10-bits (B) 12-bits
    (C) 14-bits (D) 15-bits

18. Assume that a total memory M is available with no partitions made yet. If Buddy system strategy is being used and a total of n partitions have been made to serve the request. The closest range of the requested size is
    (A) $\frac{M}{2^n+1}$ and $\frac{M}{2^n}$ (B) $\frac{M}{n}$ and $\frac{M}{n-1}$
    (C) $\frac{M}{2^n}$ and $\frac{M}{2^{n-1}}$ (D) $\frac{M}{n+1}$ and $\frac{M}{n}$

19. The memory has four free blocks of sizes 2K, 6K, 20K, 4K. The request blocks are allocated according to best fit allocation method. The allocation requests are stored in queue as shown:

Reqest no.	P_1	P_2	P_3	P_4	P_5	P_6	P_7
Reqest sizes	4 K	10 K	2 K	3 K	5 K	4 K	2 K
Usage time	1	4	2	6	3	1	8

The time at which request for P_7 will be completed is
(A) 10 unit time
(B) 14 unit time
(C) 20 unit time
(D) 15 unit time

20. A memory page containing a heavily used variable that was initialized very early and is in constant use is removed when ______ page replacement is used.
(A) LRU
(B) FIFO
(C) LFU
(D) Optimal

Previous Years' Questions

1. A processor uses 36-bit physical addresses and 32-bit virtual addresses, with a page frame size of 4 K bytes. Each page table entry is of size 4 bytes. A three-level page table is used for virtual to physical address translation, where the virtual address is used as follows: **[2008]**

- Bits 30–31 are used to index into the first level page table
- Bits 21–29 are used to index into the second level page table
- Bits 12–20 are used to index into the third level page table, and
- Bits 0–11 are used as offset within the page

The number of bits required for addressing the next level page table (or page frame) in the page table entry of the first, second and third level page tables are, respectively,
(A) 20, 20 and 20 (B) 24, 24 and 24
(C) 24, 24 and 20 (D) 25, 25 and 24

2. How many 32 K × 1 RAM chips are needed to provide a memory capacity of 256 K bytes? **[2009]**
(A) 8 (B) 32
(C) 64 (D) 128

3. In which one of the following page replacement policies, Belady's anomaly may occur? **[2009]**
(A) FIFO (B) Optimal
(C) LRU (D) MRU

4. The essential content(s) in each entry of a page table is/are **[2009]**
(A) Virtual page number
(B) Page frame number
(C) Both virtual page number and page frame number
(D) Access right information

5. A multilevel page table is preferred in comparison to a single-level page table for translating virtual address to physical address because **[2009]**
(A) It reduces the memory access time to read or write a memory location.
(B) It helps to reduce the size of page table needed to implement the virtual address space of a process.
(C) It is required by the translation look-aside buffer.
(D) It helps to reduce the number of page faults in page replacement algorithms.

6. A system uses FIFO policy for page replacement. It has four-page frames with no pages loaded to begin with. The system first accesses 100 distinct pages in some order and then accesses the same 100 pages but now in the reverse order. How many page faults will occur? **[2010]**
(A) 196 (B) 192
(C) 197 (D) 195

7. Let the page fault service time be 10 ms in a computer with average memory access time being 20 ns. If one page fault is generated for every 10^6 memory accesses, what is the effective access time for the memory? **[2011]**
(A) 21 ns (B) 30 ns
(C) 23 ns (D) 35 ns

8. Consider the virtual page reference string

1, 2, 3, 2, 4, 1, 3, 2, 4, 1

on a demand paged virtual memory system running on a computer system that has main memory size of three-page frames which are initially empty. Let LRU, FIFO and OPTIMAL denote the number of page faults under the corresponding page replacement policy. Then **[2012]**
(A) OPTIMAL< LRU < FIFO
(B) OPTIMAL < FIFO < LRU
(C) OPTIMAL = LRU
(D) OPTIMAL = FIFO

9. A RAM chip has a capacity of 1024 words of 8 bits each (1 K × 8). The number of 2 × 4 decoders with

enable line needed to construct a 16 K × 16 RAM from 1 K × 8 RAM is **[2013]**
(A) 4 (B) 5
(C) 6 (D) 7

Common data for Questions 10 and 11: A computer uses 46-bit virtual address, 32-bit physical address, and a three-level paged page table organization. The page table base register stores the base address of the first-level table (T_1), which occupies exactly one page. Each entry of T_1 stores the base address of a page of the second-level table (T_2). Each entry of T_2 stores the base address of a page of the third-level table (T_3). Each entry of T_3 stores a page table entry (PTE). The PTE is 32-bits in size. The processor used in the computer has a 1 MB 16-way set associative virtually indexed physically tagged cache. The cache block size is 64 bytes.

10. What is the size of a page in KB in this computer? **[2013]**
(A) 2 (B) 4
(C) 8 (D) 16

11. What is the minimum number of page colours needed to guarantee that no two synonyms map to different sets in the processor cache of this computer? **[2013]**
(A) 2 (B) 4
(C) 8 (D) 16

12. Assume that there are three page frames which are initially empty. If the page reference string is 1, 2, 3, 4, 2, 1, 5, 3, 2, 4, 6, the number of page faults using the *optimal replacement policy* is ———. **[2014]**

13. A computer has 20 physical page frames which contain pages numbered 101 through 120. Now a program accesses the pages numbered 1, 2, … 100 in that order, and repeats the access sequence THRICE. Which one of the following page replacement policies experiences the same number of page faults as the optimal page replacement policy for this program? **[2014]**
(A) Least-recently used (B) First-in-first-out
(C) Last-in-first-out (D) Most-recently-used

14. A system uses three page frames for storing process pages in main memory. It uses the Least Recently Used (LRU) page replacement policy. Assume that all the page frames are initially empty. What is the total number of page faults that will occur while processing the page reference string given below? **[2014]**
4, 7, 6, 1, 7, 6, 1, 2, 7, 2

15. Consider a paging hardware with a TLB. Assume that the entire page table and all the pages are in the physical memory. It takes 10 milliseconds to search the TLB and 80 milliseconds to access the physical memory. If the TLB hit ratio is 0.6, the effective memory access time (in milliseconds) is ——— **[2014]**

16. Consider a system with byte-addressable memory, 32-bit logical addresses, 4 kilobyte page size and page table entries of 4 bytes each. The size of the page table in the system in megabytes is _______. **[2015]**

17. Consider a main memory with five page frames and the following sequence of page references: 3, 8, 2, 3, 9, 1, 6, 3, 8, 9, 3, 6, 2, 1, 3. Which one of the following is true with respect to page replacement policies First In First Out (FIFO) and Least Recently Used (LRU)? **[2015]**
(A) Both incur the same number of page faults
(B) FIFO incurs 2 more page faults than LRU
(C) LRU incurs 2 more pages faults than FIFO
(D) FIFO incurs 1 more page faults than LRU

18. Consider six memory partitions of sizes 200 KB, 400 KB, 600 KB, 500 KB, 300 KB and 250 KB, where KB refers to kilobyte. These partitions need to be allotted to four processes of sizes 357 KB, 210 KB, 468 KB and 491 KB in that order. If the best fit algorithm is used, which partitions are NOT allotted to any process? **[2015]**
(A) 200 KB and 300 KB
(B) 200 KB and 250 KB
(C) 250 KB and 300 KB
(D) 300 KB and 400 KB

19. A computer system implements 8 kilobyte pages and a 32-bit physical address space. Each page table entry contains a valid bit, a dirty bit, three permission bits, and the translation. If the maximum size of the page table of a process is 24 megabytes, the length of the virtual address supported by the system is _______ bits. **[2015]**

20. Consider the following two *C* code segments. *Y* and *X* are one and two dimensional arrays of size *n* and $n \times n$ respectively, where $2 \leq n \leq 10$. Assume that in both code segments, elements of Y are initialized to 0 and each element $X[i]\ [j]$ of array *X* is initialized to $i + j$. Further assume that when stored in main memory all elements of *X* are in same main memory page frame.

Code segment 1: **[2015]**

```
    //initialize elements of Y to 0
//initialize elements X[i][j] of X to
i+j
for (i = 0; i < n; i++)
Y[i] += X[0] [i];
```

Code Segment 2:

```
    //initialize elements of Y to 0
```

```
    //initialize elements X[i] [j] of X
to i + j
    for (i = 0; i < n; i++)
    Y[i] += X[i] [0];
```

Which of the following statements is/are correct?

S_1: Final contents of array Y will be same in both code segments

S_2: Elements of array X accessed inside the for loop shown in code segment 1 are contiguous in main memory

S_3: Elements of array X accessed inside the for loop shown in code segment 2 are contiguous in main memory.

(A) Only S_2 is correct
(B) Only S_3 is correct
(C) Only S_1 and S_2 are correct
(D) Only S_1 and S_3 are correct

21. Consider a computer system with 40-bit virtual addressing and page size of sixteen kilobytes. If the computer system has a one-level page table per process and each page table entry requires 48 bits, then the size of the per-process table is ______ megabytes. **[2016]**

22. Consider a computer system with ten physical page frames. The system is provided with an access sequence ($a_1, a_2, \ldots, a_{20}, a_1, a_2, \ldots a_{20}$), where each ai is a distinct virtual page number. The difference in the number of page faults between the last-in-first-out page replacement policy and the optimal page replacement policy is ______. **[2016]**

23. In which one of the following page replacement algorithms it is possible for the page fault rate to increase even when the number of allocated frames increases? **[2016]**

(A) **LRU** (Least Recently Used)
(B) **OPT** (Optimal Page Replacement)
(C) **MRU** (Most Recently Used)
(D) **FIFO** (First In First Out)

24. Recall that Belady's anomaly is that the page-fault rate may *increase* as the number of allocated frames increases. Now, consider the following statements:

S1: *Random page replacement* algorithm (where a page chosen at random is replaced) suffers from Belady's anomaly

S2: *LRU page replacement* algorithm suffers from Belady's anomaly

Which of the following is CORRECT? **[2017]**

(A) S1 is true, S2 is true
(B) S1 is true, S2 is false
(C) S1 is false, S2 is true
(D) S1 is false, S2 is false

25. Consider a process executing on an operating system that uses demand paging. The average time for a memory access in the system is M units if the corresponding memory page is available in memory and D units if the memory access causes a page fault. It has been experimentally measured that the average time taken for a memory access in the process is X units.

Which one of the following is the correct expression for the page fault rate experienced by the process? **[2018]**

(A) $(D - M)/(X - M)$ (B) $(X - M/(D - M)$
(C) $(D - X/(D - M)$ (D) $(X - M/(D - X)$

Chapter 5

File Systems, I/O Systems, Protection and Security

LEARNING OBJECTIVES

- *File systems*
- *File management systems*
- *File system architecture*
- *Device drivers*
- *Basic input/output supervisor*
- *Logical input/output*
- *Access methods*

File Systems

The file system consists of two distinct parts:

1. Collection of files
2. Directory structure

File A file is a named collection of related information that is recorded on secondary storage. The files must have

1. Long-term existence
2. Sharable between processes
3. Structure

File attributes A typical file attributes are

1. Name
2. Identifier
3. Type
4. Location
5. Size
6. Protection
7. Time, date and user identification

File operations The operations that are applied on files are

1. Creation
2. Deletion
3. Closing
4. Reading
5. Writing

File types A common technique for implementing file types is to include the type as part of the file name. The name is split into two parts:

1. A name
2. An extension (usually separated by a period character)

The type of a file may be

1. Executable (exe, com, bin)
2. Object (obj, o)
3. Source code (c, cc, java)
4. Batch (bat, sh)
5. Text (txt, doc)
6. Word processor (wp, text, doc)
7. Library (lib)
8. Print or view (ps, pdf, jpg)
9. Archive (zip, tar)
10. Multimedia (mpeg, mov, rm)

File structure The four common terms of file systems are

1. Field
   - Basic element of data
   - Contains a single value
   - Has a particular length and data type

2. Record
   - It is a collection of related fields
   - It is treated as a unit

3. File
   - It is a collection of similar records
   - Treated as a single entity
   - Has file names
   - Access to file may be restricted or unrestricted

4. Database
   - Collection of related data.
   - Relationship exists among elements.

File Management Systems

It is a set of system software that provides services to users and applications in the use of files. Objectives of file management systems are as follows:

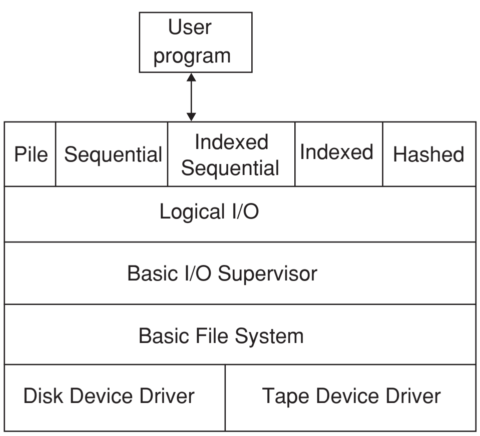
1. To meet the data management needs and requirements of the user including storage of data.
2. To guarantee, that the data in the file are valid.
3. To optimize performance (i.e., throughput, response time).
4. To provide Input/Output (I/O) support for a variety of storage device types.
5. To minimize or eliminate the potential for lost or destroyed data.
6. To provide a standardized set of I/O interface routines.
7. To provide I/O support for multiple users.

The minimal set of requirements from user's point of view for an interactive, general purpose, file system are as follows:

1. Ability to create, delete, read, write and modify files.
2. Controlled access to other users files.
3. Control the type of accesses to files.
4. Restructure the user's files.
5. Able to move data between files.
6. Ability to back up and recover user's files.
7. Able to access a file by name.

File System Architecture

The file system architecture is shown below:



Device Drivers

1. It is at the lower part.
2. Communicates directly with peripheral devices.
3. Initiative to start I/O operations on a device.
4. Processes the completion of an I/O request.

Basic File System

1. Mainly concerned with I/O.
2. Exchanges blocks of data.
3. Deals with placement of blocks.
4. Deals with buffering blocks in main memory.

Basic I/O Supervisor

1. Responsible for file initiation and termination.
2. Maintain control structures.
3. Selects the device while file I/O is to be performed.
4. Deals with scheduling access to optimize performance.
5. Part of the operating system (OS).

Logical I/O

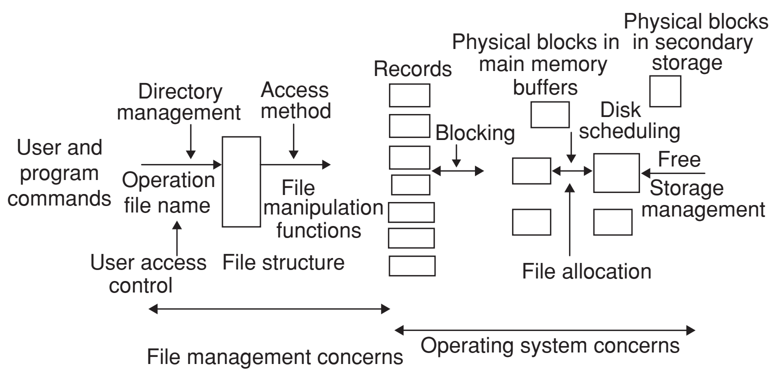
1. Enables users and application to access records.
2. Provides general purpose record I/O capability.
3. Maintains basic data about file.

Access Methods

1. They reflect different file structures.
2. Provide different ways to access and process data.
3. Access methods are as follows:
   - Sequential: read next, write next
   - Direct: read block n, write block n

File Management Functions

The functions of a file system is shown below:



File Organization and Access

File organization refers to the logical structuring of the records as determined by the way in which they are accessed. We choose a particular file organization based on

1. Short access time
2. Ease of update
3. Economy of storage
4. Simple maintenance
5. Reliability

We will discuss five types of file organizations:

1. The pile
2. The sequential file
3. The indexed sequential file
4. The indexed file
5. The direct or hashed file

The pile The pile organization is shown in Figure 1:

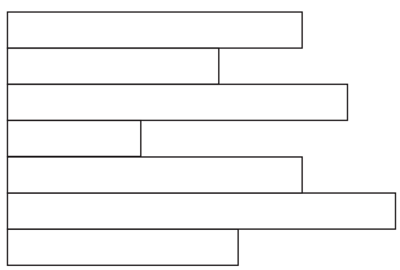


Figure 1 Pile file.

1. Data are collected in order they arrive.
2. The aim is to accumulate mass of data and save.
3. Records may have different fields.
4. There is no structure.
5. Record are accessed by exhaustive search.
6. There can be variable length records.
7. This type of files are encountered when data are collected and stored prior to processing or when data are not easy to organize.

The sequential file The sequential file is shown in Figure 2.

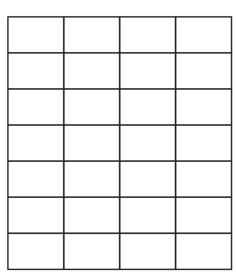

Figure 2 Sequential file.

1. Fixed format used for records.
2. Records are of same length.
3. All fields are of the same order and length.
4. One field is the key field. It uniquely identifies the record. Records are stored in a key sequence.
5. New records are placed in a log file or transaction file.
6. Batch update is performed to merge the log file with the master file.
7. Used in batch applications.
8. Not suitable for interactive applications.

Indexed sequential file

1. Index provides a look up capability to quickly reach the vicinity of the desired record.
2. It contains key field and a pointer to the main file.
3. Index is searched to find highest key value that is equal to or precedes the desired key value.
4. Search continues in the main file at the location indicated by the pointer.
5. New records are added to an overflow file.
6. Record in main file that precedes it is updated to contain a pointer to the new record.
7. The overflow is merged with main file during a batch update.
8. Multiple indexes for the same key can be set up to increase efficiency.

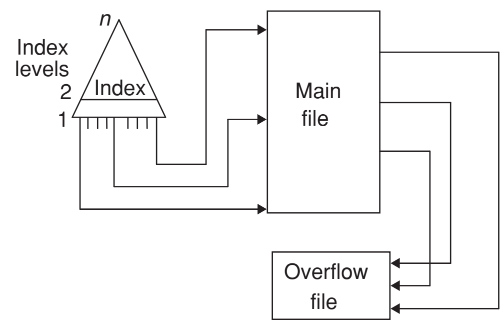

Figure 3 Indexed file.

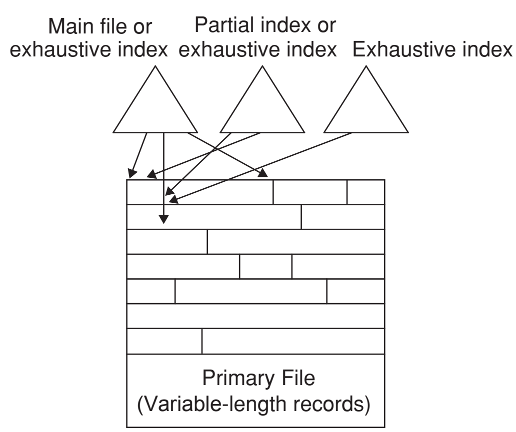
9. Key field required for each record.
10. It uses multiple indexes for different key fields.
11. It may contain exhaustive index that contains one entry for every record in the main file or partial index.



12. Used in the applications where timeliness of information is critical and where data are rarely processed exhaustively.

Direct or Hashed file

1. This file has the capability to access any block of a known address.
2. Key field required in each record.
3. No concept of sequential ordering.

Figure 4 shows hashed file organization:

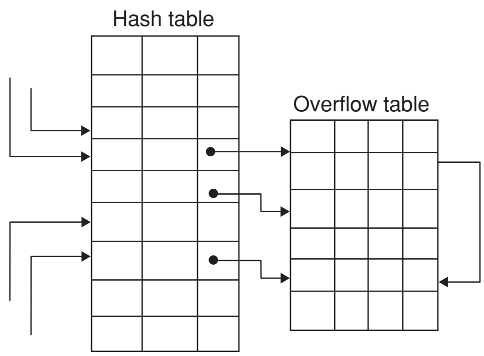


Figure 4 Hashed file organization.

File Directories

The collection of files is a file directory.

Contents

1. Contain information about files, such as attributes, location, and ownership.
2. Itself a file owned by the OS.
3. It provides mapping between file names and the file themselves.

Directory Structure

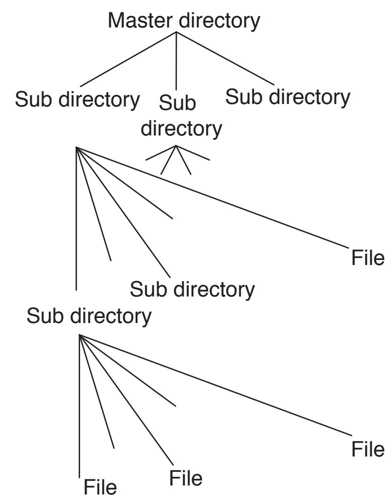
1. It consists of list of entries, one for each file.
2. Sequential file with the name of the file serving as the key.
3. Provides no help in organizing the files.
4. Not scalable (same name cannot be used for two different files).
5. As directory grows in size, searching is too time consuming.

Two-level Directory Structure

1. Contains one directory for each user and a master directory.
2. The master directory contains entry for each user
3. User directory is a simple list of files for that user.
4. File naming conflict is solved.

Hierarchical or Tree-structured Directory

1. Contains master directory with user directory underneath it.
2. Each user directory may have subdirectories and files as entries.



3. Files can be located by following a path from the root, or master directory down various branches which is called *pathname* for the file.
4. Current directory is called the *working directory*.
5. Files are referenced relative to the working directory.

Naming The use of a tree-structured directory minimizes the difficulty in assigning unique names. Any file in the system can be located by following a path from the root or master directory down various braches until the file is reached.

Path name The series of directory names, culminating in the file name itself, constitutes a path name for the file.

Example: Time/Gate/Exam/OS
The slash is used to delimit names in the sequence. The name of master directory is implicit, because all paths starts at that directory. Files can also be referenced from the working directory.

File sharing It has got two issues, such as:

1. Access rights
2. Management of simultaneous access

Access rights Users or groups of users are granted certain access rights to a file. A wide range of access rights has been used. The access rights may be

1. None
2. Knowledge
3. Execution
4. Reading
5. Appending
6. Updating
7. Changing protection
8. Deletion

These access rights can be specified to specific users or user groups or all users.

Record Blocking For I/O to be performed, records must be organized as blocks. Given the size of a block, there are three methods of blocking that can be used:

1. Fixed blocking
2. Variable length spanned blocking
3. Variable length unspanned blocking.

Fixed blocking

1. Fixed-length records (Figure 5) are used and an integral number of records are stored in a block.
2. Possibility of internal fragmentation.
3. Used for sequential files.

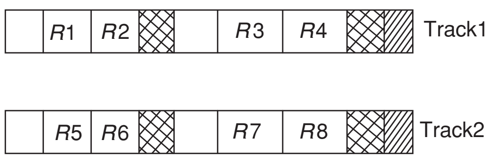


Figure 5 Fixed blocking.

Variable length spanned blocking Variable length records are used and are packed into blocks with no unused space. Some records can span two blocks. These do not limit the size of records.

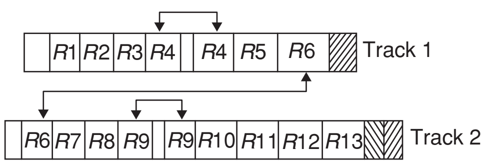

Figure 6 Variable blocking: spanned.

Variable length unspanned blocking Variable length records (Figure 7) are used, but spanning is not employed. There is wasted space in most blocks and limits record size.

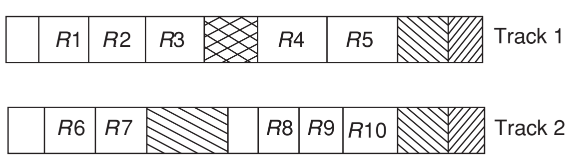

Figure 7 Variable blocking: unspanned.

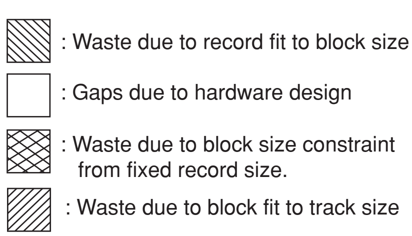


Secondary Storage Management

1. Space (or blocks) must be allocated to files on disk.
2. Need to keep track of the space available (free blocks) for allocation to files.
3. Preallocation of blocks to files can be used to allocate space for files. For this, it needs to know the maximum size of the file at the time of creation.

File Allocation

Preallocation Versus Dynamic Allocation

1. A preallocation policy requires that the maximum size of a file be declared at the time of the file creation request. For many applications, it is difficult to estimate the file size.
   It is better to use dynamic allocation, which allocates space to a file in portions as needed.

Portion size The portion size which is allocated to a file may be

1. Variable, large contiguous portions.
2. Blocks

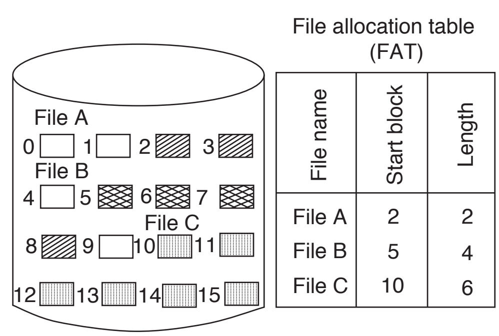
Some strategies for dealing with fragmentation of free space are as follows:

1. *First-fit*: Choose the first unused contiguous group of blocks of sufficient size.
2. *Best-fit*: Choose the smallest unused group that is of sufficient size.
3. *Nearest-fit*: Choose the unused group of sufficient size that is closest to the previous allocation.

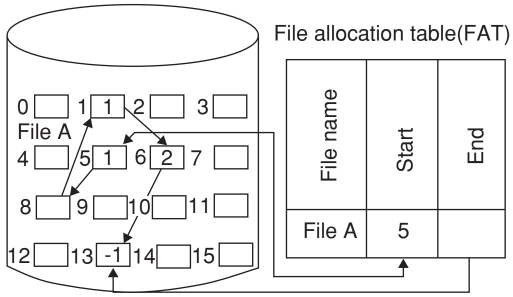
File allocation methods It has three methods as follows:

1. Contiguous allocation
2. Chained allocation
3. Indexed allocation

Contiguous allocation Here, a single set of blocks is allocated to a file at the time of creation. Only a single entry in the file allocation table is created consisting of starting block and length of the file. It exhibits external fragmentation and performs compaction.

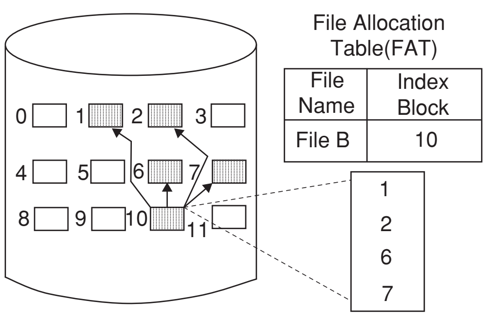


Linked or chained allocation The allocation is done on basis of individual block. Each block contains a pointer to the next block in the chain. Only single entry is created in the file allocation table consisting of starting block and length of file. There occurs no external fragmentation and it is best for sequential files. There is no accommodation of principle of locality. If block size is n, then only $n - 1$ units of data are stored and 1 unit stores the link information.

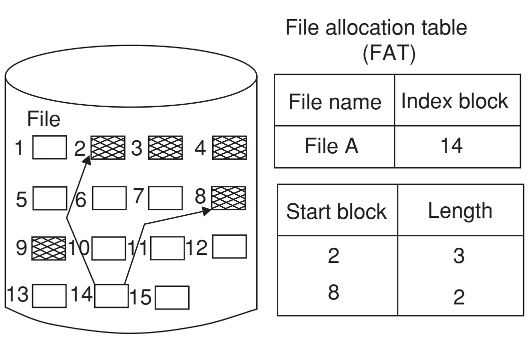


Indexed file allocation The file allocation table contains a separate one level index for each file. The index has one entry for each portion allocated to the file. The file allocation table contains block number for the index. If a file requires n blocks, then $n + 1$ blocks are used, where the first block contains index information (pointers to data blocks).

Index Allocation with Block Pointers



Indexed Allocation with Variable length Portion



Example 1: A direct access of file has fixed size 50 byte records. Assuming the first record is record 1, the first byte of record 10 will be at what logical location?

Solution:
Total records = 50 × 10 = 500
First record is record 1. This record is already read.
Logical location of first byte = 500 – 50 = 450
The correct logical location = 450 + 1 = 451.

Example 2: A sequential access file has fixed-size 32-byte records. Assuming that the first record is record 0, the first byte of record 20 will be at what location?

Solution: Since the first record is record 0, the first byte of record 20 will be at logical location = 32 × 20 = 640

Free Space Management

In addition to file allocation table, disk allocation table is also required to know what blocks on the disk are available. Some of the free space management techniques are as follows:

1. Bit tables
2. Chained free portions
3. Indexing
4. Free block list

Bit tables This method uses a vector containing, one bit for each block on the disk. Each entry of a '0' corresponds to a free block and each '1' corresponds to a block in use.

Advantage

1. Easy to find one or a contiguous group of free blocks.
2. Smaller in size.

The amount of memory required for a block bitmap will be

$$\frac{\text{Disk size in (bytes)}}{8 \times \text{file system block size}}$$

Chained free portion The free portions may be chained together by using a pointer and length value in each free portion. This method has negligible space overhead. This method is suitable for all file allocation methods. The disk will become quite fragmented, after some use. It is slower for individual block file creation and also for deletion.

Indexing It treats the free space as a file and uses an index table (same as in file allocation). The index should be on the basis of variable size portions rather than blocks.

Free block list Here, each block is assigned a number sequentially and the list of the numbers of all free blocks is maintained in a reserved portion of the disk.

Volumes

It is a collection of addressable sectors in a secondary memory that an OS or application can use for data storage. The sectors in a volume need not be consecutive on a physical storage device. (a single disk equals one volume).

Unix File Management

I-nodes (Index Node)

UNIX files are administered by the OS by means of i-node. An i-node (index node) is a control structure that contains the key information needed by the OS for a particular file.

The attributes of the file as well as its permissions and other control information are stored in the i-node. The

exact i-node structure varies from UNIX implementation to another. The FreeBSD i-node structure is shown in Figure 8.

File Allocation

1. It is done on a block basis.
2. Allocation is dynamic.
3. The blocks of a file on disk are not necessarily contiguous.
4. An indexed method is used to keep track of each file, with i-node includes a number of direct pointers and three indirect pointers.

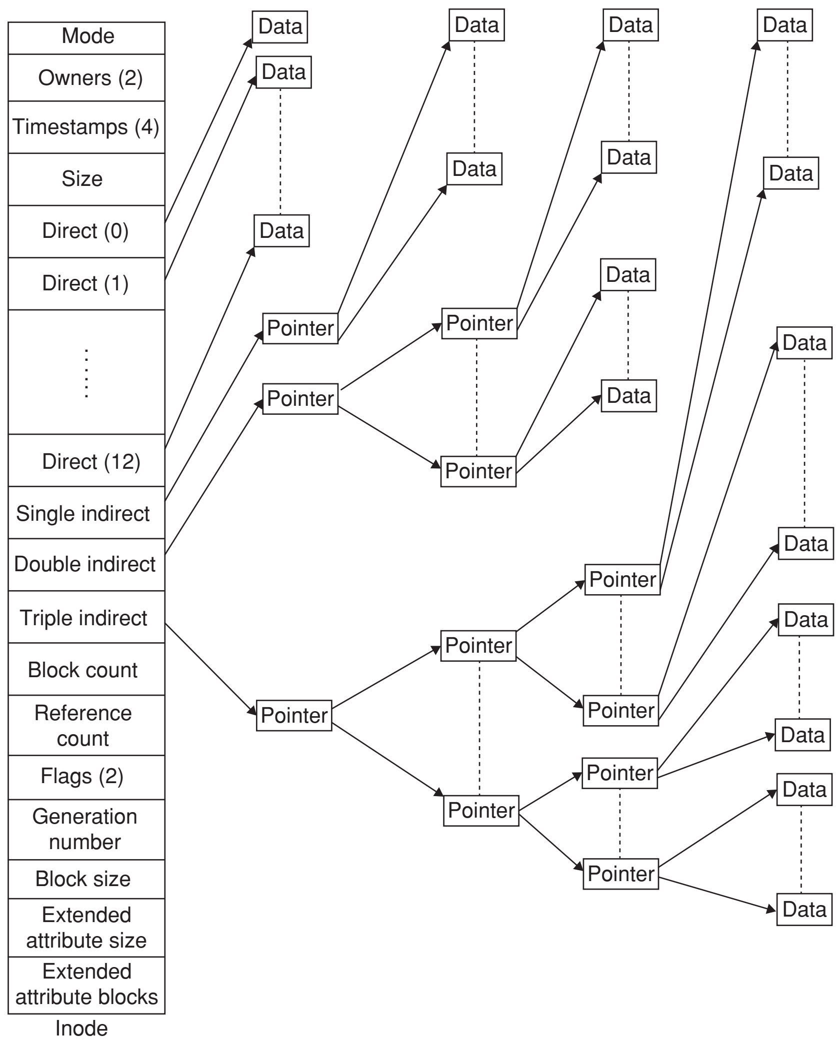


Figure 8 Structure of free BSD i-node and file.

5. The free BSD i-node includes 120 bytes of address information that is organized as fifteen 64-bit addresses.
6. The first 12 addresses point to the first 12 data blocks of the file.
7. If the file requires more than 12 data blocks, one or more levels of indirection are used as follows:
   - The thirteenth address in the i-node points to a block on disk that contains the next portion of the index. This is referred to as the *single indirect block*.
   - If the file contains more blocks, the fourteenth address in the i-node points to a double indirect block. Each block consists of single indirect blocks, each of which contains pointers to file blocks.
   - If the file contains still more blocks, the fifteenth address in the i-node points to a triple indirect block that is a third level of indexing. This block points to additional double indirect blocks.

The capacity of FreeBSD file with 4 kB block size is shown below:

Level	Number of Blocks	Number of Bytes
Direct	12	48 K
Single indirect	512	2 M
Double indirect	$512 \times 512 = 256$ K	1 G
Triple indirect	512×256K $= 128$ M	512 G

The total number of data blocks in a file depends on the capacity of the fixed-size blocks in the system. In FreeBSD, the minimum block size is 4 kB, and each block can hold a total of 512 block addresses. Thus, the maximum size of a file with this block size is over 500 GB.

Windows NT File System

The windows NT file system provides a combination of reliability, compatibility and performance, which are not available in the FAT file system.

1. It will quickly perform standard file operations, such as write, read and search.
2. It also performs file-system recovery on very large hard disks.
3. NTFS file system formatting on a volume results in the creation of several system files and the master file table (MST), which contains information about all the files and folders on the NTFS (Figure 9).

Partition boot sector	Master file table	System files	File area

Figure 9 NTFS after formatting.

4. It includes security features required for high-end personal computers and file servers.
5. It supports data access control and ownership privileges.
6. Folders shared on a Windows NT are assigned specific permissions.
7. It allows users to assign permissions to individual files.

I/O Systems

Design Objectives of OS

Two objectives of OS for I/O systems are as follows:

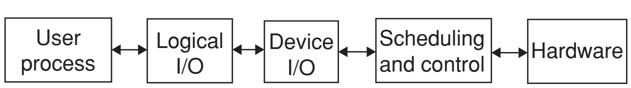
1. Efficiency
2. Generality

Logical Structure of the I/O Function

The three most important logical structures are as follows:

1. Local peripheral devices
2. Communication ports
3. File system

Local Peripheral Device



Logical I/O

Manages general I/O functions on behalf of user processes, allowing them to deal with the device in terms of a device identifier and simple commands, such as open, close, read, write.

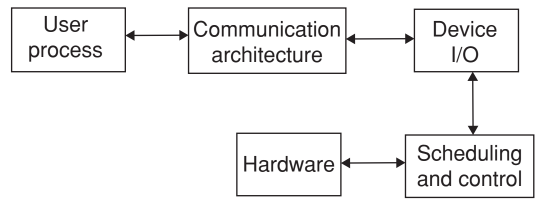
Device I/O

The requested operations and data are converted into appropriate sequences of I/O instructions, channel commands and controller orders.

Scheduling and Control

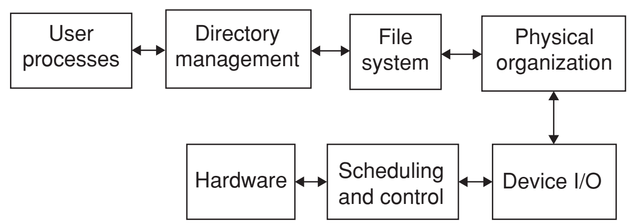
The actual queuing and scheduling of I/O operations occurs at this layer as well as the control of the operations. Interrupts are handled. I/O status is collected and reported.

Communication Port



Here, the communication architecture may itself consist of a number of layers.

File System



Directory management Here, the symbolic file names are converted to identifiers that either reference the file directly or indirectly through a file descriptor or index table.

File system This layer deals with the logical structure of files and with the operations that can be specified by users, such as open, close, read, write.

Physical organization Allocation of secondary storage space and main storage buffers is generally treated here.

I/O buffering In buffering, we perform input transfers in advance of requests being made and perform output transfers sometime after the request is made. We will discuss

1. Single buffering
2. Double buffering
3. Circular buffering

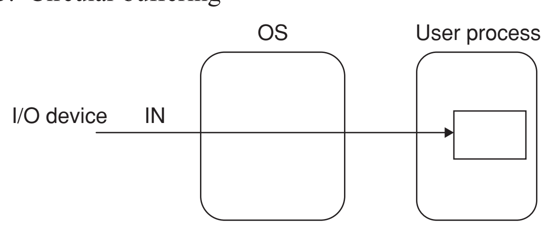


Figure 10 No buffering.

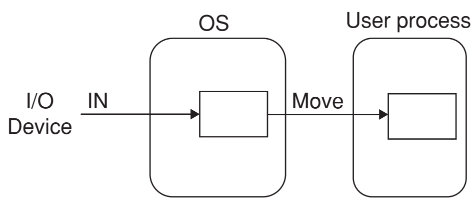

Figure 11 Single buffering.

- When a user process issues an I/O request, the OS assigns a buffer in the system portion of main memory to the operation.
- Provides a speed up compared to the lack of system buffering.
- For block oriented devices, input transfers are made to the system buffer. When the transfer is complete, the process moves the block into user space and immediately requests another block. This is same for block-oriented output.
- Suppose that T is the time required to input one block and that C is the computation time that intervenes between input requests.
  Without buffering, the execution time per block = $T + C$.
  With a single buffer, the execution time per block = max $[C, T] + M$,
  where M = Time required to move the data from the system buffer to user memory.
- For stream-oriented I/O, the single buffering scheme can be used in a line-get-a-time fashion or a byte-at-a-time fashion.

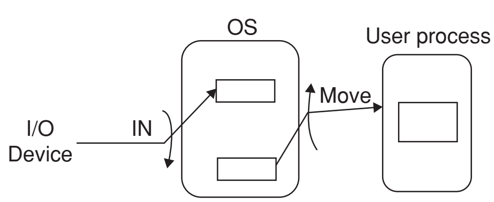

Figure 12 Double buffer

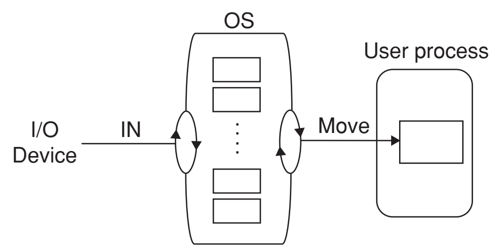
- An improvement over single buffer.
- A process now transfers data to one buffer while the OS empties the other. This is known as *double buffering* or *buffer swapping*.
- For block-oriented transfer, the estimated execution time is max $[C, T]$.
- The stream-oriented transfer may be line-at-a-time or byte-at-a-time.

Automatic and Explicit Buffering

An indefinite length queue is provided in automatic buffering. Sender never blocks to copy a message. No specifications are present for providing automatic buffering. One method is to reserve large amount of memory. In this method, most of the memory is wasted.

The size of the queue is provided in explicit buffering. Sender will block if the requested space is more than available. In this scheme, memory wastage is less likely to happen.

Circular Buffer



1. Here, more than two buffers are used. Each individual buffer is one unit of circular buffer.

Kernal I/O Subsystem

Kernel I/O provides I/O-related services. It is built on the hardware and device driver infrastructure.

One of the responsibilities of Kernal I/O subsystem is to protect itself from the erroneous process and malice users.

Services provided by the I/O subsystem are as follows:

1. Scheduling
2. Buffering
3. Caching
4. Spooling
5. Device reservation
6. Error handling

Disk Scheduling

Hard Disk Performance Parameters (Terminologies)

Seek time It is defined as the time required to move the disk arm to the required track. It consists of

1. Initial start-up time
2. The time taken to traverse the tracks that has to be crossed once the access arm is up to speed.

$$\text{Seek time, } T_s = m \times n + S$$

where T_s = Estimated seek time
n = Number of track traversed
m = Constant that depends on the disk drive
S = Start-up time

Rotational delay Time required to reach the desired sector by read/write head. Rotational speed ranges from 5400 to 10,000 rpm.

1. Floppy disks typically rotate between 300 and 600 rpm.
2. For 1,00,000 rpm, the average rotational delay will be 3 ms.

Transfer time The transfer time to or from the disk depends on the speed of the disk.

$$T = \frac{b}{rN}$$

where, T = Transfer time
b = Number of bytes to be transferred
N = Number of bytes on a track
r = Rotation speed in revolutions/second

Total average access time

$$T_a = T_s + \frac{1}{2r} + \frac{b}{rN}$$

$T_s \rightarrow$ average seek time

Hard Disk Scheduling Algorithms

Disk bandwidth and fast access time are to be considered. Bandwidth is the total number of bytes transferred divided by the total time between the first request for service and completion of the last transfer.

FCFS (First Come First Served) The disk in controller processes the I/O requests the order in which they arrive, thereby moving backwards and forwards across the surface of the disk to get the next requested location each time (Figure 10).

Example 3: A disk queue has the following requests to read tracks:

87, 170, 40, 150, 36, 72, 66, 15

Consider the disk head is initially at cylinder 60. Total head movement = (87 – 60) + (170 – 87) + (170 – 40) + (150 – 40) + (150 – 36) + (72 – 36) + (72 –66) + (66 – 15) = 27 + 83 + 130 + 110 + 114 + 36 + 6 + 51 = 557 cylinders

Average head movement $= \frac{557}{8} = 69.6$ cylinders

Advantage

Improved response time as a request gets response in fair amount of time.

Disadvantages

1. Involves a lot of random head movements and disk rotations.
2. Throughput is not efficient.
3. Used in small systems only where I/O efficiency is not very important.

Shortest Seek Time First (SSTF) When a disk operation finishes, choose the request that is closer to the current head position or choose the request that has minimum seek time from the current head position.

Example 4: Consider the following requests: 87, 170, 40, 150, 36, 72, 66, 15. Find the average head movement for SSTF.

The initial head position is say 60. Now, closest to the head position is the request at cylinder 66. Then, the closest to 66 is 72, closest request to 72 is 87, and so on. Total head movements = (66 – 60) + (72 – 66) + (87 – 72) + (87 – 40) + (40 – 36) + (36 – 15) + (150 – 15) + (170 – 150) = 6 + 6 + 15 + 47 + 4 + 21 + 135 + 20 = 254 cylinders

Average head movements $= \frac{254}{8} = 31.75$ cylinders

Advantages

1. It minimizes latency
2. Better throughput than FIFO method

Disadvantages

1. Starvation occurs if some process has to wait for long time until its requests are satisfied.
2. SSTF services requests for those tracks which are highly localized.

SCAN/elevator algorithm The disk head constantly moves from the most inner cylinder to the outer cylinder and then it changes its direction back towards the centre. As the head moves, if there is a request for the current disk position then it is satisfied.

1. It is known as *elevator algorithm* because it services all the request of going up and then reaching at the top, it goes downward.
2. It needs two information:
   - Direction of head movement
   - Last position of the disk head

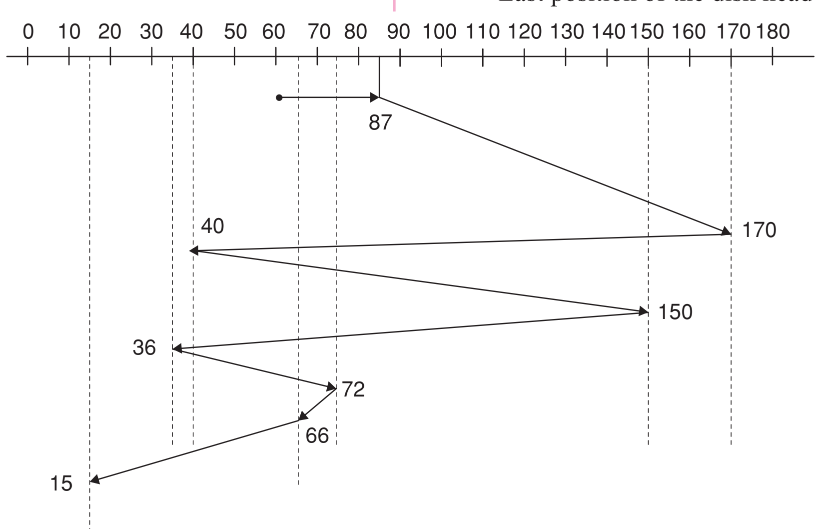


Figure 13 FCFS.

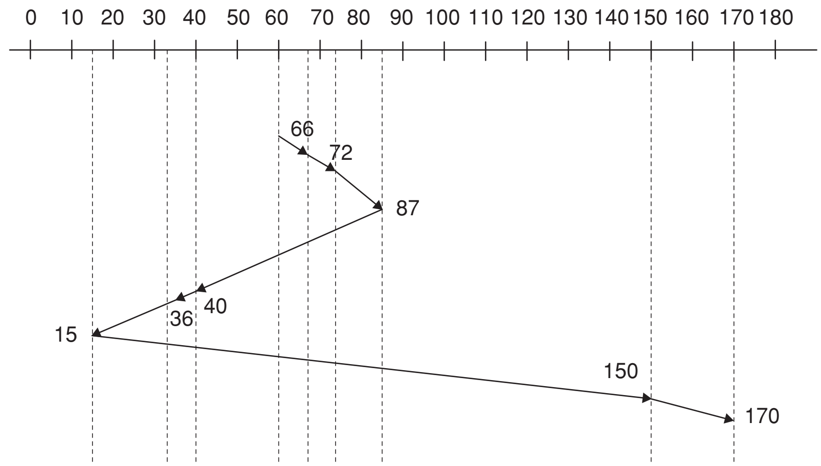

Figure 14 SSTF

Example 5: For the following track requests: 87, 170, 40, 150, 36, 72, 66, 15. (Initially head is at track 60 to the arm is moving outwards.

Total head movement = (66 – 60) + (72 – 66) + (87 – 72) + (150 – 87) + (170 – 150) + (180 – 170) + (180 – 40) + (40 – 36) + (36 – 15)

= 6 + 6 + 15 + 63 + 20 + 10 + 140 + 4 + 21

= 285 cylinders

Average head movement $= \frac{285}{8} = 35.6$ cylinders

Advantages

1. Throughput better than FIFO.
2. Basic for most scheduling algorithms.
3. Eliminates the discrimination.
4. No starvation.

Disadvantages

1. Because of the continuous scanning of disk from end to end, the outer tracks are visited less often than the mid-range tracks.
2. Disk arm keeps scanning between two extremes; this may result in wear and tear of the disk assembly.
3. Certain requests arriving ahead of the arm position would get immediate service but some other requests that arrive behind the arm position will have to wait for the arm to return back.

C–SCAN algorithm (one–way elevator algorithm) It treats the cylinder as a circular list. The head sweeps from the innermost cylinder to the outermost cylinder, satisfying the waiting requests in order of their locations. When it reaches the outermost cylinder, it sweeps back to the innermost cylinder without satisfying any requests and then starts again.

Example 6: Consider the cylinders requests:
87, 170, 40, 150, 36, 72, 66, 15 Starting cylinder = 60th (arm moving outwards)

Total head movement = (66 – 60) + (72 – 66) + (87 – 72) + (150 – 87) + (170 – 150) + (180 – 170) + (180 – 0) + (15 – 0) + (36 – 15) + (40 – 36)

= 6 + 6 + 15 + 63 + 20 + 10 + 180 + 15 + 21 + 4 = 340

Average head movement $= \frac{340}{8} = 35.6 = 42.5$

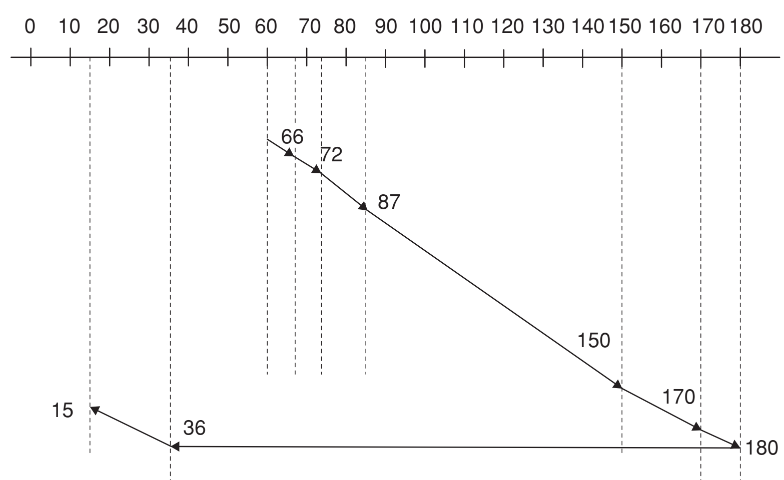

Figure 15 SSTF

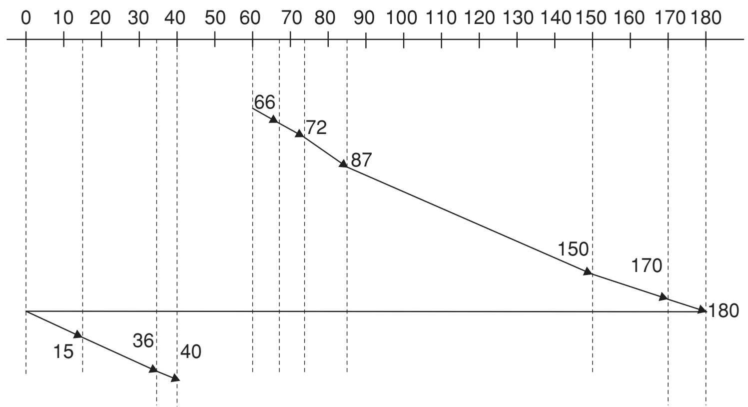

Figure 16 C–SCAN

Advantage

Lower service variability.

Disadvantages

1. An average head movement is more compared to SCAN algorithm.
2. Increase in the total seek time

LOOK/SEEK algorithm Look is similar to SCAN, but stops moving inwards (or) outwards when there are no more requests in that direction.

Example 7: Consider the following requests:
87, 170, 40, 150, 36, 72, 66, 15 initially head is at track 60 (moves outwards).

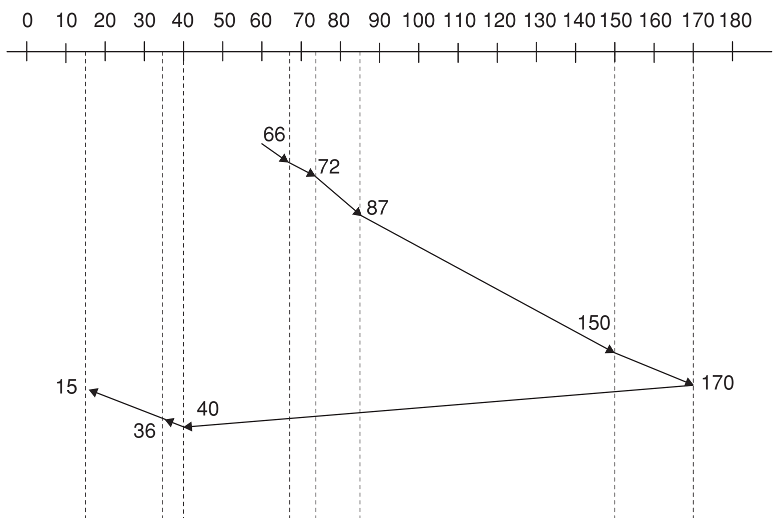

Figure 17 LOOK

$$\text{Average head movement} = \frac{275}{8} = 34.37$$

C–LOOK/C–SEEK algorithm The head moves inwards servicing requests until there are no more requests in that direction. Then it jumps to the outer most outstanding request.

Magnetic Disk and Factors that Determine Access Speed

The factors that determine the access speed are rotational speed, which is measured in revolutions per minute are seek time, the time taken to read or write the particular sector of the disk.

The other factors are sequential read, sequential write, random read and random write. These vary enormously, but for spinning disks one can expect 25 Mbps to 150 Mbps for sequential read and write it is about 3 Mbps to 50 Mbps for the random read and write.

RAID (Redundant Array of Independent Disks)

1. It is multiple disk database design.
2. It consists of seven levels, zero through six.
3. Characteristics of RAID Levels:
   - RAID is a set of physical disk drives viewed by the OS as a single logical drive.
   - Data are distributed across the physical drives of an array in a scheme known as striping.
   - Redundant disk capacity is used to store parity information, which guarantees data recoverability in case of a disk failure.

RAID Level 0:

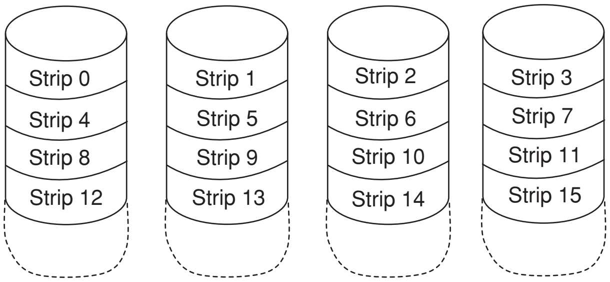

Figure 18 Non-redundant (RAID0)

1. It does not include redundancy.
2. N disks are required.
3. Data available in RAID level 0 is lower than single disk.
4. It has high data transfer capacity.
5. It has high I/O request rate.

RAID Level 1:

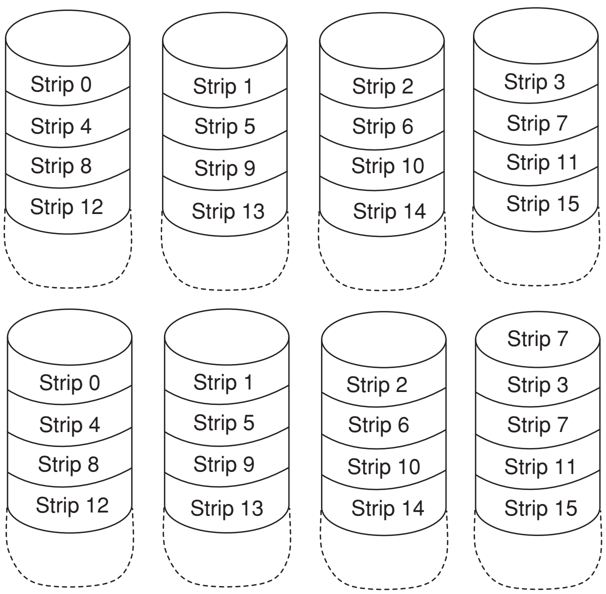

Figure 19 RIAD 1 (Mirrored)

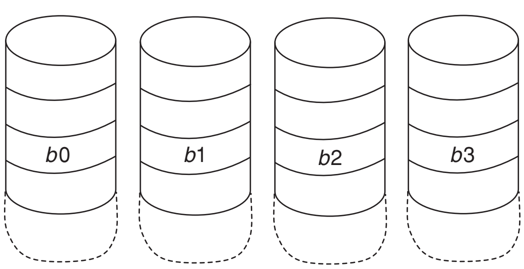
1. Redundancy is achieved by the simple expedient of duplicating all the data.
2. 2N disks required.
3. Data availability is higher than RAID 2, 3, 4, or 5. But lower than RAID 6.
4. Recovery from failure is simple.
5. RAID1 costs more.

RAID Level 2:



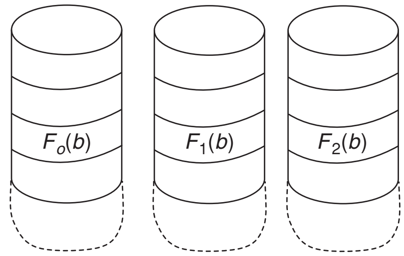


Figure 20 RAID 2 (Redundancy through Hamming code).

6. Here redundancy is achieved through hamming code.
7. $N + m$ disks required.

RAID Level 3:

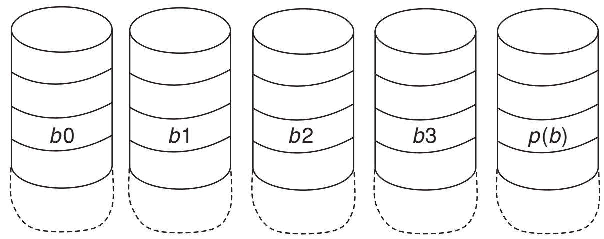

Figure 21 RAID 3 (bit-interleaved parity)

1. It has bit interleaved parity.
2. Provides parallel access.
3. $N + 1$ disks required.

RAID Level 4:

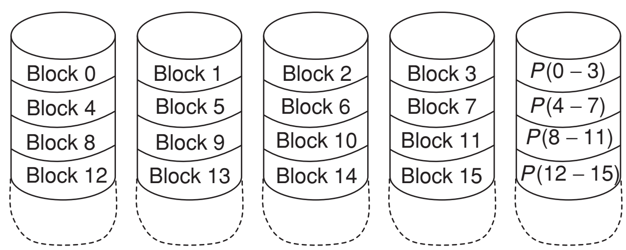

Figure 22 RAID 4 (Block-level parity)

1. $N + 1$ disks required.
2. Provides independent access.
3. Consider an array of five drives in which X_0 through X_3 contains data and X_4 is the parity disk.

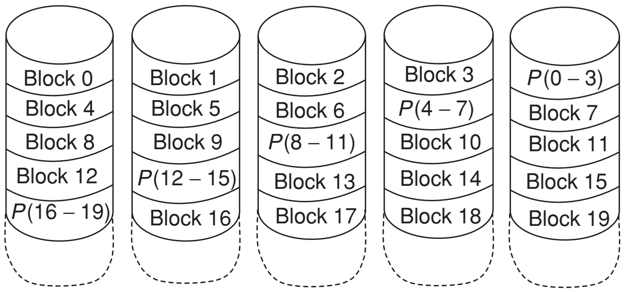
Suppose that a write is performed that only involves a strip on disk X_1. Initially for each bit i, we have the following relationship:

$$X_4(i) = X_3(i) \oplus X_2(i) \oplus X_1(i) \oplus X_0(i)$$

After the update, with potentially altered bits indicated by a prime symbol:

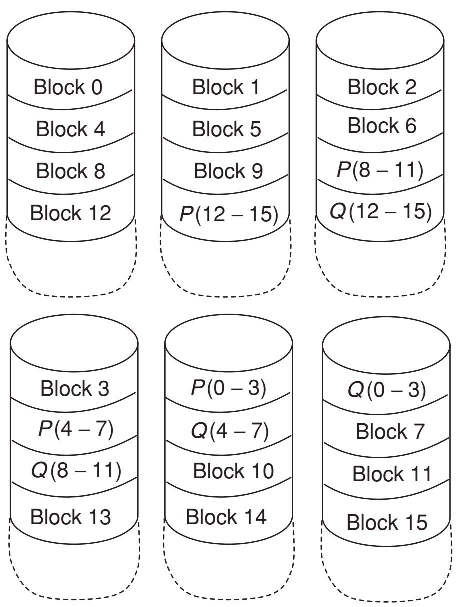
$$\begin{aligned} X_4'(\text{i}) &= X_3(i) \oplus X_2(i) \oplus X_1'(i) \oplus X_0(i) \\ &= X_3(i) \oplus X_2(i) \oplus X_1'(i) \oplus X_0(i) \oplus X_1(i) \oplus X_1(i) \\ &= X_4(i) \oplus X_1(i) \oplus X_1'(i) \end{aligned}$$

RAID Level 5:



1. It has block level distributed parity.
2. Provides independent access.
3. It has $N + 1$ disks.

RAID Level 6:

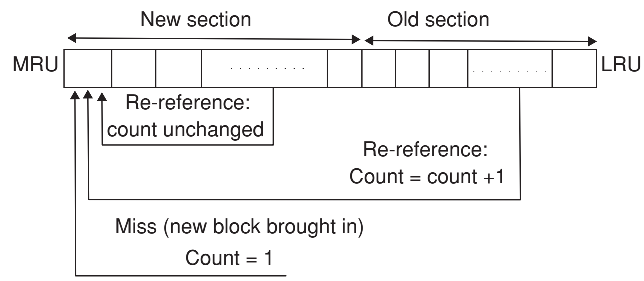


1. It has dual redundancy.
2. It provides independent access.
3. It has $N + 2$ disks.

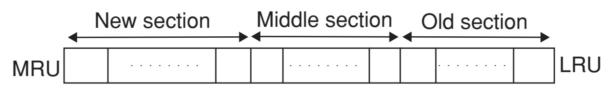
Disk Cache:

1. It is a buffer in main memory for disk sectors.
2. The cache contains a copy of some of the sectors on the disk.
3. Replacement policy:
   - LRU
   - LFU

But these two replacement policies lead to poor performance. So a new technique frequency-based replacement is proposed. Two alternatives of frequency-based technique are shown below:



(A) FIFO



(B) Use of three sections.

In FIFO, the blocks are logically organized in a stack; where the top part of the stack is the new section. When there is a cache hit, the referenced block is moved to top of the stack. If the block was already in the new section, its reference count is not incremented; otherwise it is incremented by 1.

In another technique, we divide the stack into three sections: New, middle and old. Here only blocks in the old section are eligible for replacement.

Protection and Security

System protection Protection refers to a mechanism for controlling the access of programs, processes or users to the resources defined by a computer system.

Principles of Protection

Programs, users and even systems are given just enough privileges to perform their tasks. This is the principle of *least privilege*.

Domain of protection A computer system is a collection of processes and objects. The objects may be software or hardware objects. The operations that are possible may depend on the object.

A process should be allowed to access only those resources for which it has authorization. At any time, a process should be able to access only those resources that it currently requires to complete its task. This requirement is referred as *need to know principle* and is useful in limiting the amount of damage, which a faulty process can cause in the system.

Domain structure Each domain defines a set of objects and the types of operations that may be invoked on each object.

The ability to execute an operation on an object is an *access right*. A domain is a collection of access rights, each of which is an ordered pair <obj-name, rights-set>

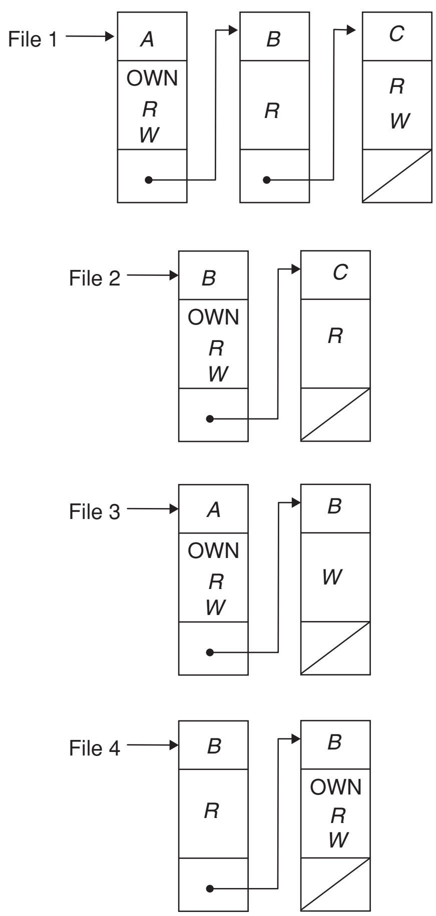
File System Security

1. A general model of access control for file management is an access matrix.
2. The basic elements of the model are as follows:
   - *Subject*: An entity capable of accessing objects.
   - *Object*: Anything to which access is controlled.
   - *Access right*: The way in which an object is accessed by a subject.

Access matrix format is shown below:

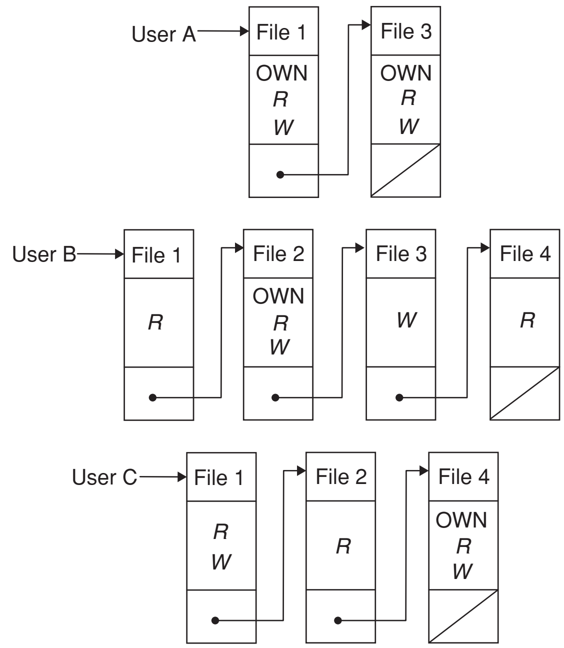
	File 1	File 2	File 3	File 4	Account 1	Account 2
User A	OWN R W		OWN R W		Inquiry credit	
User B	R	OWN R W	W	R	Inquiry debit	Inquiry credit
User C	R W	R		OWN R W		Inquiry Debit

The access matrix may be decomposed by columns, yielding access control lists. The access control list for above matrix is



Note: This allows users that are not explicitly listed as having special rights to have a default set of rights.

Decomposition by row yields. Capability tickets.



Note: These tickets would have to be held in a region of memory inaccessible to users.

System security This is the protection afforded to an automated information system in order to attain objectives of preserving the integrity, availability and confidentiality of information system resources.

Objectives of Computer Security

Confidentiality Preserving authorized restrictions on information access and disclosure, including means for protecting personal privacy and proprietary information.

Integrity Guarding against improper information modification or destruction, including ensuring information non-repudiation and authenticity.

Availability Ensuring timely and reliable access to and use of information.

Authenticity The property of being genuine and being able to be verified and trusted.

Accountability The security goal that generates the requirement for actions of an entity to be traced uniquely to that entity.

Threats, Attacks and Assets

Threats and attacks *Unauthorized disclosure* is the threat to confidentiality. The attacks of following this threat are as follows:

1. *Exposure*: Sensitive data are directly released to an unauthorized entity.
2. *Interception*: An unauthorized entity directly accesses sensitive data traveling between authorized sources and destinations.

3. *Inference*: A threat action where an unauthorized entity indirectly accesses sensitive data by reasoning from characteristics or by-products of communications.
4. *Intrusion*: An unauthorized entity gains access to sensitive data by circumventing a system's security protections.

Deception Threat to either system integrity or data integrity. Types of attacks that can result are as follows:

1. *Masquerade*: An unauthorized entity gains access to a system or performs a malicious act by posing as an authorized entity.
2. *Falsification*: False data deceive an authorized entity.
3. *Repudiation*: An entity deceives another by falsely denying responsibility for an act.

Disruption A circumstance or event that interrupts or prevents the correct operation of system services and functions. Attacks for this threat are as follows:

1. *Incapacitation*: Prevents or interrupts system operation by disabling a system component.
2. *Corruption*: Undesirably alters system operation by adversely modifying system functions or data.
3. *Obstruction*: A threat action that interrupts delivery of system service by hindering system operation.

Usurpation A circumstance or event that results in control of system services or functions by an unauthorized entity. Attacks with this threat are as follows:

1. *Misappropriation*: An entity assumes unauthorized logical or physical control of a system resource.
2. *Misuse*: Causes a system component to perform a function or service that is detrimental to system security.

Threats and assets The assets of a computer are as follows:
1. Hardware
2. Software
3. Data
4. Communication lines

Hardware A major threat to computer system hardware is the threat to availability (e.g., theft of CD-ROMS).

Software
1. A key threat to software is an attack on availability (e.g., deletion of software).
2. A threat to integrity.
3. A threat to confidentiality.

Data Threats to data are an attack on
1. Availability
2. Confidentiality
3. Integrity

Communication lines and networks Two types of attacks:
1. Passive attacks
2. Active attacks

Passive attacks
1. These are in the nature of monitoring of the transmissions.
2. Attackers obtain information that is being transmitted.
3. Two types of passive attacks:
   - Release of message contents.
   - Traffic analysis
4. These are very difficult to detect because they do not involve any alteration of the data.

Active attacks
1. These attacks involves some modification of the date stream or the creation of a false stream and can be subdivided into four categories:
   - Replay
   - Masquerade
   - Modification of messages
   - Denial of service
2. It is difficult to prevent active attacks absolutely.

Intruders Three types of intruders:

Masquerader An individual who is not authorized to use the computer and who penetrates a systems access controls to exploit a legitimate user's account. He is likely to be an outsider.

Misfeasor A legitimate user who accesses data, programs or resources for which such access is not authorized or who is authorized for such access but misuses his or her privileges (generally an insider).

Clandestine user An individual who seizes supervisory control of the system and uses this control to evade auditing and access controls or to suppress audit collection (either outsider or insider).

Hackers Those who hack into computers do so for the thrill of it or for status. Attackers often took for targets of opportunity and then share the information with others.

Criminals Organized group of hackers have become a widespread and common threat to internet based systems.

Malicious software overview The most sophisticated types of threats to computer systems are presented by programs that exploit vulnerabilities in computing systems. These threats are referred as malicious software (or) malware.

1. It is designed to cause damage to or use up the resources of a target computer.
2. There are two types of malicious software:
   - Those that need a host program.
     Example: Viruses, logic bombs.
   - Those that are independent.
     Example: Worms, bot programs.
3. We can also differentiate between two types of software threats:
   - That do not replicate. These programs are activated by a trigger.
     Example: Logic bombs, backdoors.

- Those that replicate.
  Example: Viruses, worms

Backdoor (trapdoor) It is a secret entry point into a program that allows someone who is aware of the backdoor to gain access without going through usual security access procedures.

Logic bomb It is a program inserted into software by an intruder. It lies dormant until a predefined condition is met; the program then triggers an unauthorized act.

Trojan Horse It is an apparently useful program, containing hidden code that, when invoked, performs some unwanted or harmful function.

Mobile code It is a software that can be shipped unchanged to a heterogeneous collection of platforms and execute with identical semantics.

Viruses A computer virus is a piece of software that can infect other programs by modifying them.

Nature of Viruses

A virus can do anything that other programs do. It attaches itself to another program and executes secretly when the host program is run. Three parts of computer virus are as follows:

1. Infection mechanism
2. Trigger
3. Payload

Phases of computer virus are

1. Dormant phase
2. Propagation phase
3. Triggering phase
4. Execution phase

Types of Virus

1. Encrypted virus
2. Stealth virus
3. Polymorphic virus
4. Metamorphic virus

Worms A worm is a program that can replicate itself and send copies from computer to computer across network connections.

Bots A bot is a program that secretly takes over another internet attached computer and then uses that computer to launch attacks that are difficult to trace to the bot's creator.

Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Given a system using unspanned blocking and 100 byte blocks. A file contains records 30, 40, 55, 80, 30, 40. What percentage of space will be wasted in the blocks allocated for the file?
(A) 31.25% (B) 41.25%
(C) 51.25% (D) 62.15%

2. Disk requests come into the disk driver for cylinders 15, 25, 10, 2, 35, 9, 42 in that order. The disk head is currently positioned over cylinder 15. A seek takes 6 msec per cylinder moved. What is the total seek time using First Come First Served Algorithm?
(A) 750 msec (B) 650 msec
(C) 550 msec (D) 450 msec

3. A Java application needs to load 50 libraries. To load each library, one disk access is required. Seek time to access the location is 10 ms. Rotational speed is 6000 rpm. The total time needed to load all libraries is
(A) 0.65 sec (B) 0.75 sec
(C) 0.85 sec (D) 1 sec

4. A program has just read the 13th record in a sequential access file. If it wants to read the 10th record next, how many records must the program read to input the tenth record?
(A) 5 (B) 0
(C) 10 (D) 13

5. A disk is formatted into 40 sectors and 20 tracks. The disk rotates at 200 ms in one revolution. The time taken by the head to move from the centre to the rim is 10 ms. There are three different files stored on the disk:
File P : Sector 2, track 4
File Q : Sector 5, track 1
File R : Sector 6, track 2
Calculate the average latency time required for the three files.
(A) 22.55 ms (B) 32.22 ms
(C) 21.66 ms (D) 30.22 ms

6. Match the following

(a) RAID0	(1) Parallel access
(b) RAID1	(2) Striping
(c) RAID2	(3) Use hamming code
(d) RAID3	(4) Mirrored

(A) a – 2, b – 4, c – 3, d – 1
(B) a – 1, b – 2, c – 3, d – 4
(C) a – 3, b – 2, c – 4, d – 1
(D) a – 4, b – 1, c – 2, d – 3

7. The correct matching for the following pairs is

(A) Disk scheduling	(1) Round Robin
(B) Batch processing	(2) SCAN
(C) Time sharing	(3) LIFO
(D) Interrupt processing	(4) FIFO

(A) A – 3, B – 4, C – 2, D – 1
(B) A – 4, B – 3, C – 2, D – 1
(C) A – 2, B – 4, C – 1, D – 3
(D) A – 2, B – 1, C – 4, D – 3

8. A program P reads and processes 2000 consecutive records from a sequential file stored on device R without using any file system facilities. Given the following:
Size of each record = 3500 bytes
Access time of R = 20 ms
Data transfer rate of $R = 500 \times 10^3$ bytes/sec
CPU time to process each record = 5 m sec
What is the elapsed time of P if R contains unblocked records and P does not use buffering?
(A) 64 sec (B) 46 sec
(C) 34 sec (D) 17 sec

9. A disk has 19456 cylinders, 16 heads and 63 sectors per track. The disk spins at 5400 rpm. Seek time between adjacent tracks is 2 ms. Assuming the read/write head is already positioned at track 0, how long does it take to read the entire disk?
(A) 35 min (B) 68 min
(C) 58 min (D) 53 min

10. On a disk with 1000 cylinders, numbered 0 to 999, compute the number of tracks the disk arm must move to satisfy all the requests in the disk queue using SCAN algorithm. Assume the last request serviced was at track 345 and the head is moving towards 0. The queue in FIFO order contains requests for the following tracks:
123, 874, 692, 475, 105, 376
(A) 219 (B) 635
(C) 845 (D) 1219

Common data for questions 11 to 14: In the operation of a certain disk drive mechanism, a disk is formatted into 20 sectors and 10 tracks. The disk can be rotated either clockwise or anti-clockwise. The times required to perform certain operations are as follows:

I. Rotate the disk through one revolution = 200 ms
II. Move the disk head from the centre to the rim = 20 ms
III. Read and transmit one block of data = 0.3 ms

Three files are stored on the disk:
File A: 2 blocks at track 6
File B: 5 blocks at track 2
File C: 1 block at track 5

11. The disk head is initially at sector 0, track 0. If all three files A, B and C are to be read in the minimum amount of time, they should be read in the following order:
(A) A, B, C (B) A, C, B
(C) B, C, A (D) C, A, B

12. The disk head is initially at sector 0, track 0. The files are read in the order C, B, A. The total time to read the files is
(A) 143.9 ms (B) 100.4 ms
(C) 114.0 ms (D) 102.6 ms

13. The most nearly average latency time for the sequence CBA is:
(A) 1 ms (B) 7 ms
(C) 27 ms (D) 50 ms

14. The most nearly average seek time for CBA is
(A) 1 ms (B) 8 ms
(C) 30 ms (D) 50 ms

15. A CD has 150 tracks rotating at 3500 rpm. Average seek time for consecutive tracks is 0.1 ms, the disk is subjected to read data from the track numbers 89, 75, 112, 5. What is the total seek time if the requests are served unidirectionally (C-Scan) and the first request determines initial direction? Assume that the current position of the head is at track 100.
(A) 20.2 ms (B) 16.9 ms
(C) 21.3 ms (D) 14 ms

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. The strategy that allocates the smallest possible chunk of disk space that is sufficient to the file is
(A) Nearest fit (B) Best fit
(C) Worst fit (D) First fit

2. If a process of 200 kB is transferred from backing store to memory and average disk latency is 10 ms, then what would be the total swap time, if transfer ratio is 2 Mbps?
(A) 10 ms
(B) 20 ms
(C) 30 ms
(D) 40 ms

3. Let us assume that the user process is 10 MB in size and backing store is a standard hard disk with a transfer rate of 40 MB per second. Let the average latency is 8 millisecond. Find actual time transfer of the 10 MB process to or from main memory?
(A) 8 ms (B) 250 ms
(C) 258 ms (D) 516 ms

4. Disk scheduling involves deciding
(A) which disk should be accessed next
(B) the order in which disk access requests must be serviced.
(C) the physical location when files should be accessed in the disk
(D) disk access time and an unused space.

5. The root directory of a disk should be placed
   (A) at a fixed address in the memory
   (B) anywhere on the disk
   (C) at a fixed location on the system disk
   (D) at a location on floppy.
6. Direct access methods are not effectively supported by
   (A) Contiguous allocation
   (B) Linked allocation
   (C) Indexed allocation
   (D) Sequential allocation
7. In which of the following directory systems, it is possible to have multiple paths for a file, starting from the root directory?
   (A) Single-level directory
   (B) Two-level directory
   (C) Tree-structured directory
   (D) A cyclic graph directory
8. The most common system's security method is:
   (A) Passwords
   (B) Key card systems
   (C) Surveillance system
   (D) Lock system
9. Trojan Horse programs
   (A) are legitimate programs that allow unauthorized access.
   (B) are hacker programs that do not show up on the system
   (C) really do not work
   (D) are immediately discovered
10. Which of the following is a program that spreads throughout the network?
    (A) Trojan Horse (B) Virus
    (C) TSR (D) Worm
11. A program has just read the 15th record in a sequential access file. If it wants to read the 10th record next, how many records must the program read to input the tenth record?
    (A) 0 (B) 5
    (C) 4 (D) 10
12. Formatting of a floppy disk refers to
    (A) Arranging the data on the disk in contiguous fashion
    (B) Writing the directory
    (C) Erasing the system area
    (D) Writing identification information on all tracks
13. Sector interleaving in disks is done by
    (A) the disk manufacturer
    (B) the disk controller card
    (C) the operating system
    (D) the user
14. Disk I/O is done in terms of
    (A) Tracks
    (B) Blocks
    (C) Bits
    (D) Bytes
15. How many six-letter passwords can be constructed using lowercase letters and digits?
    (A) 26^6 (B) 10^6
    (C) 36^6 (D) 35^6

Previous Years' Questions

1. Consider a disk drive with the following specifications: **[2005]**
   16 surfaces, 512 tracks/surfaces, 512 sectors/track, 1 KB/sector, rotation speed 3000 rpm. The disk is operated in cycle stealing mode whereby whenever one 4 byte word is ready it is sent to memory; similarly, for writing, the disk interface reads a 4 byte word from the memory in each DMA cycle. Memory cycle time is 40 nsec. The maximum percentage of time that the CPU gets blocked during DMA operation is:
   (A) 10 (B) 25
   (C) 40 (D) 50
2. Consider a disk pack with 16 surfaces, 128 tracks per surface and 256 sectors per track. 512 bytes of data are stored in a bit serial manner in a sector. The capacity of the disk pack and the number of bits required to specify a particular sector in the disk are, respectively: **[2007]**
   (A) 256 Mbyte, 19 bits
   (B) 256 Mbyte, 28 bits
   (C) 512 Mbyte, 20 bits
   (D) 64 Gbyte, 28 bits
3. For a magnetic disk with concentric circular tracks, the seek latency is not linearly proportional to the seek distance due to **[2008]**
   (A) non-uniform distribution of requests
   (B) arm starting and stopping inertia
   (C) higher capacity of tracks on the periphery of the platter
   (D) use of unfair arm scheduling policies
4. Consider a file of 16384 records. Each record is 32 bytes long and its key field is of size 6 bytes. The file is ordered on a non-key field, and the file organization is unspanned. The file is stored in a file system with block size 1024 bytes, and the size of a block pointer is 10 bytes. If the secondary index is built on the key field of the file, and a multi-level index scheme is used to store the secondary index, the number of first-level and second-level blocks in the multi-level index are, respectively **[2008]**

(A) 8 and 0 (B) 128 and 6
(C) 256 and 4 (D) 512 and 5

5. Consider a disk system with 100 cylinders. The requests to access the cylinders occur in following sequence: **[2009]**

4, 34, 10, 7, 19, 73, 2, 15, 6, 20

Assuming that the head is currently at cylinder 50, what is the time taken to satisfy all requests if it takes 1ms to move from one cylinder to adjacent one and shortest seek time first policy is used?

(A) 95 ms (B) 119 ms
(C) 233 ms (D) 276 ms

Common data for questions 6 and 7: A hard disk has 63 sectors per track, 10 platters each with 2 recording surfaces and 1000 cylinders. The address of a sector is given as a triple $\langle c, h, s \rangle$, where c is the cylinder number, h is the surface number and s is the sector number. Thus, the 0th sector is addressed as $\langle 0, 0, 0 \rangle$, the 1st sector as $\langle 0, 0, 1 \rangle$, and so on

6. The address <400, 16, 29> corresponds to the sector number: **[2009]**

(A) 505035 (B) 505036
(C) 505037 (D) 505038

7. The address of the 1039th sector is **[2009]**

(A) $\langle 0, 15, 31 \rangle$ (B) $\langle 0, 16, 30 \rangle$
(C) $\langle 0, 16, 31 \rangle$ (D) $\langle 0, 17, 31 \rangle$

8. A file system with 300 GByte disk uses a file descriptor with 8 direct block addresses, 1 indirect block address and 1 doubly indirect block address. The size of each disk block is 128 bytes and the size of each disk block address is 8 bytes. The maximum possible file size in this file system is **[2012]**

(A) 3 Kbytes
(B) 35 Kbytes
(C) 280 Kbytes
(D) dependent on the size of the disk

9. Consider a hard disk with 16 recording surfaces (0–15) having 16384 cylinders (0–16383) and each cylinder contains 64 sectors (0–63). Data storage capacity in each sector is 512 bytes. Data are organized cylinder-wise and the addressing format is <cylinder no., surface no., sector no.>. A file of size 42797 KB is stored in the disk and the starting disk location of the file is <1200, 9, 40>. What is the cylinder number of the last sector of the file, if it is stored in a contiguous manner? **[2013]**

(A) 1281 (B) 1282
(C) 1283 (D) 1284

10. A FAT (File allocation table)-based file system is being used, and the total over head of each entry in the FAT is 4 bytes in size. Given a 100×10^6 bytes disk on which the file system is stored and data block size is 10^3 bytes, the maximum size of a file that can be stored on this disk in units of 10^6 bytes is ______? **[2014]**

11. Consider a disk pack with a seek time of 4 milliseconds and rotational speed of 10000 rotations per minute (RPM). It has 600 sectors per track and each sector can store 512 bytes of data. Consider a file stored in the disk. The file contains 2000 sectors. Assume that every sector access necessitates a seek, and the average rotational latency for accessing each sector is half of the time for one complete rotation. The total time (in milliseconds) needed to read the entire file is ________. **[2015]**

12. Suppose the following disk request sequence (track numbers) for a disk with 100 tracks is given: 45, 20, 90, 10, 50, 60, 80, 25, 70. Assume that the initial position of the R/W head is on track 50. The additional distance that will be traversed by the R/W head when the Shortest Seek Time First (SSTF) algorithm is used compared to the SCAN (Elevator) algorithm (assuming that SCAN algorithm moves towards 100 when it starts execution) is ______ tracks. **[2015]**

13. Consider a typical disk that rotates at 15000 rotations per minute (RPM) and has a transfer rate of 50×10^6 bytes/sec. If the average seek time of the disk is twice the average rotational delay and the controller's transfer time is 10 times the disk transfer time, the average time (in milliseconds) to read or write a 512-byte sector of the disk is ________ **[2015]**

14. Consider a disk queue with requests for I/O to blocks on cylinders 47, 38, 121, 191, 87, 11, 92, 10. The C-LOOK scheduling algorithm is used. The head is initially at cylinder number 63, moving towards larger cylinder numbers on its servicing pass. The cylinders are numbered from 0 to 199. The total head movement (in number of cylinders) incurred while servicing these requests is _____. **[2016]**

15. In a file allocation system, which of the following allocation scheme(s) can be used if no external fragmentation is allowed? **[2017]**

I. Contiguous
II. Linked
III. Indexed

(A) I and III only (B) II only
(C) III only (D) II and III only

16. Consider a storage disk with 4 platters (numbered as 0, 1, 2 and 3), 200 cylinders (numbered as 0, 1, ..., 199), and 256 sectors per track (numbered as 0, 1, ..., 255). The following 6 disk requests of the form [sector number, cylinder number, platter number] are

received by the disk controller at the same time:

[120, 72, 2], [180, 134, 1], [60, 20, 0], [212, 86, 3], [56, 116, 2], [118, 16, 1]

Currently the head is positioned at sector number 100 of cylinder 80, and is moving towards higher cylinder numbers. The average power dissipation in moving the head over 100 cylinders is 20 milliwatts and for reversing the direction of the head movement once is 15 milliwatts. Power dissipation associated with rotational latency and switching of head between different platters is negligible.

The total power consumption in milliwatts to satisfy all of the above disk requests using the Shortest Seek Time First disk scheduling algorithm is _________. **[2018]**

Test

Operating System

Time: 60 min.

Directions for questions 1 to 30: Select the correct alternative from the given choices.

1. A program is _____ entity, while a process is _____ entity.
   (A) Active, passive
   (B) Active, sometimes active
   (C) Passive, active
   (D) Both (B) and (C)
2. All the information associated with a specific process is contained in:
   (A) Process control block
   (B) Program control block
   (C) TLB
   (D) Heap
3. Kernel-level threads and user-level threads are supported, respectively, by _____.
   (A) Operating system and operating system
   (B) Operating system and user
   (C) User and user
   (D) None of these
4. Which of the following is false about user-level threads?
   (A) User-level threads are visible to the programmer and are unknown to the Kernel.
   (B) These are faster to create.
   (C) Kernel never interferes.
   (D) There is no effect of a system call () on process.
5. Which of the following interprocess communication models are implemented using system calls?
   (A) Shared memory
   (B) Message passing
   (C) Both (A) and (B)
   (D) Neither (A) nor (B)
6. Peterson's solution
   (i) is restricted to two processes
   (ii) share two data items turn and flag [i]
   (iii) mutual exclusion is achieved
   (iv) is a hardware solution

   Which of the above are true?
   (A) (i), (ii), (iii)
   (B) (ii), (iii), (iv)
   (C) (iv), (i), (ii)
   (D) (i), (ii), (iii), (iv)
7. Which of the following requires a mode switch from one thread to another?
   (A) One process multiple thread
   (B) User-level thread
   (C) Kernel-level threads
   (D) Both (B) and (C)
8. When a process is created, its state is
   (A) New
   (B) Ready
   (C) Block
   (D) Suspend
9. The data section of a process in memory contains
   (A) Local variables, function parameters
   (B) Return addresses
   (C) Global variables
   (D) None of the above
10. Which one of the following is true about process states?
    (i) A process which is running must have terminated as next state.
    (ii) From running state process can go to either waiting, ready or terminated state.
    (iii) Only one process can run at any instant.
    (iv) Ready process can go to waiting state.

    (A) (i), (ii), (iii)
    (B) (ii) and (iii) only
    (C) (i) and (iv) only
    (D) (ii), (iii), (iv)
11. Message passing model of inter process communication can be
    (A) Blocking only
    (B) Blocking and non-blocking
    (C) Synchronous and asynchronous
    (D) Both (B) and (C)
12. The definition of wait( ) is as follows:
    ```
    wait (S) {
    while (S <=0);
    S - - ;
    }
    ```
    The semicolon after while statement, signifies
    (A) Infinite looping
    (B) Blank statement
    (C) Depends on interpretation of compiler
    (D) No operation
13. To avoid race condition, the number of processes using the critical sections is/are:
    (A) 1 (B) 2
    (C) 3 (D) More than 3
14. The 'Critical Section' is the region in which
    (A) Any number of processes can enter without any permission
    (B) Only one process enters at a time and others wait for it.
    (C) Section is very critical
    (D) None of these

15. What does process control block contain?
(A) Process Identification
(B) Process state information
(C) Process control information
(D) All of the above

16. Match the following

(i) Multiprogramming	(x) Managing multiple processes executing on multiple computers
(ii) Multiprocessing	(y) Management of multiple processes within a uniprocessor system.
(iii) Distributed process Management	(z) Management of multiple processes within a multiprocessor.

(A) (i) –y (ii) –z (iii) –x
(B) (i) –z (ii) –x (iii) –y
(C) (i) –y (ii) –x (iii) –z
(D) Ambiguous

17. For '*n*' number of fork( ) system call, how many parent and child processes will be created?
(A) 1, $2^n - 1$, respectively
(B) 1, 2^n, respectively
(C) $2^n - 1$, 1, respectively
(D) n, $2n$, respectively

18. If the value of binary semaphore is initialized with 1 and three wait( ) operations are performed, how many processes are there in the block list?
(A) 1 (B) 0
(C) 3 (D) 2

19. A counting semaphore is initialized with the value 3. A list of '*P*' and '*V*' operations are performed on the semaphore as: 1*P*, 2*V*, 2*P*, 3*V*, 5*P*, 7*V*, 2*P*, 3*V*.
The final value of semaphore is?
(A) 5 (B) 8
(C) 7 (D) 6

20. The final value of semaphore after 10 '*P*' operations and 23 '*V*' operations is 1. What will be the initial value of this counting semaphore?
(A) –14 (B) –13
(C) –12 (D) –11

21. For a machine-instruction approach to enforce mutual exclusion, following are its properties:
(i) starvation and deadlock free
(ii) it is applicable to any number of processes.
(iii) it can be used to support multiple critical sections, each defined by its own variable.
(iv) it is simple, easy to verify and employed with busy waiting

Which of the above is false?
(A) (iv) only (B) (ii), (iii) only
(C) (i), (ii) only (D) (i) only

22. Consider the following code:

```
if (fork( ) == 0)
{
a = a + 5;
printf("%d,%d\n",a,&a);
}
else
{
a = a - 5;
printf("%d,%d\n",a,&a);
}
```

Let p, q be the values printed by the parent process, and s, t be the values printed by the child process. Which one of the following is true?
(A) $p = s + 10$ and $q = t$
(B) $p = s + 10$ and $q \uparrow t$
(C) $p + 10 = s$ and $q = t$
(D) $p + 10 = s$ and $q \uparrow t$

23. Consider the following statements with respect to user-level threads:
(i) Context switch is faster with kernel-supported threads.
(ii) For user-level threads, a system call can block the entire process.
(iii) Kernel-supported threads can be scheduled independently.
(iv) User-level threads are transparent to the Kernel.

Which of the above statements are true?
(A) (i), (iii) and (iv) only
(B) (ii) and (iii) only
(C) (i) and (iii) only
(D) (i) and (ii) only

24. Suppose there are '*n*' CPUs and '*m*' processes such that $m > n$. What will be the minimum and maximum number of ready, running and blocked process, respectively?
(A) 0, 0, 0 and m, n, m (B) 1, m, 1 and n, n, n
(C) m, 1, 0 and m, m, n (D) 0, 0, 0 and n, m, m

25. Consider the following signal semaphore code signal (semaphore *s)

```
{
s.value++;
if( ____(I)_____ )
{
    remove a process P from S.list;
    ____(II)_____
    }
}
```

Choose the suitable options for (I) and (II), respectively
(A) S.value = 0 and wakeup(P);
(B) S.value <= 0 and wakeup(P);
(C) S.value <0 and block( );
(D) S.value <= 0 and block( );

26. Consider the methods used by processes P_1 and P_2 for accessing their critical sections whenever needed. The initial values of shared Boolean variables S_1 and S_2 are randomly assigned.

Method used by P_1

While ($S_1 = = S_2$);
Critical section
$S_1 = S_2$;

Method used by P_2

While ($S_1 \,!= S_2$);
Critical section
$S_2 = !(S_1)$;

Which of the following statements describes the properties achieved?

(A) Mutual exclusion but not progress
(B) Progress only
(C) Bounded waiting, progress
(D) Mutual exclusion, progress, bounded waiting

27. Consider the following statements regarding spin locks:

(i) No context switch is required when a process wait on a lock
(ii) Spin locks are useful when locks are expected to be held for short times.
(iii) They are often employed on multiprocessor systems
(iv) Process 'spins' while waiting for a lock

Choose the correct option:

(A) (i), (ii), (iii), (iv) are true
(B) Only (i) and (ii) are true
(C) (iii) is false
(D) (ii) is true and (iv) is false

Common data for questions 28, 29 and 30: From the Readers-Writers problem, the data structure for reader process is:

```
semaphore mutex, wrt;
int readcount;
```

```
while(1)
{
wait(mutex);
readcount++;
if(readcount == 1)
wait(wrt);
signal(mutex);

_ _ _ _ _

_ _ _ _ _
wait(mutex);
readcount - -;
if(readcount ==0)
signal(wrt); signal(mutex);
}
```

mutex and wrt are initialized to 1 and readcount is initialized to 0.

28. Mutual exclusion for readers is attained by

(A) Wrt
(B) Mutex
(C) Readcount
(D) Both (A) and (B)

29. Which of the following semaphore or semaphores is used by the first or last reader that enters or exits the critical section?

(A) Wrt
(B) Mutex
(C) Readcount
(D) Both (A) and (B)

30. The readcount variable keeps track of how many processes are _______.

(A) Currently reading the object
(B) Currently writing the object
(C) Waiting in the queue
(D) Reading the shared data

Answer Keys

1. C	**2.** A	**3.** B	**4.** D	**5.** B	**6.** A	**7.** C	**8.** A	**9.** C	**10.** B

Operating Systems Test 1

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices.

1. Which of the following service is provided by an Operating System?
   (i) Access to I/O Devices
   (ii) Controlled access to files
   (iii) System Access
   (iv) Accounting
   (A) (i), (ii) (B) (iii), (iv)
   (C) (i), (ii), (iii) (D) (i), (ii), (iii), (iv)
2. In which of the following modes, privileged instructions will be executed?
   (A) Kernel mode only
   (B) User mode only
   (C) Either kernel mode or user mode
   (D) execution of privileged instruction is independent of mode
3. In which of the following environment, the computer memory can hold three, four or more programs and a single CPU switches among all of them for execution?
   (A) Uniprogramming (B) Multiprogramming
   (C) Multiprocessing (D) Both (B) and (C)
4. What is the principle objective of Time sharing system?
   (A) Maximize processor use
   (B) Minimize response time
   (C) Maximize memory usage
   (D) Minimize CPU idle time
5. Which of the following will not be included in the Process Control Block of a process?
   (A) Process state (B) Program counter
   (C) Priority (D) None of the above
6. Which of the following best explains 'process spawning'?
   (A) The OS creates a process at the explicit request of another process.
   (B) The OS creates a process to perform a function on behalf of a user program.
   (C) A process is created when a user logs on to the system.
   (D) The OS creates a process as per its requirement.
7. For which of the following reason, a process will move from 'Running' state to 'Blocked' state?
   (A) Timeout (B) Dispatch
   (C) Suspend (D) Event wait
8. If a process is in secondary memory and is available for execution as soon as it is loaded into main memory, then it is in __________ state.
   (A) Ready (B) Blocked
   (C) Blocked/Suspend (D) Ready/Suspend
9. Which of the following will be a reason for Process Suspension?
   (A) Swapping
   (B) Interactive user request
   (C) Parent process request
   (D) All the above
10. Which of the following is TRUE?
    (A) The overhead involved in mode switch is more compared to process switch.
    (B) The overhead involved in process switch is more compared to mode switch.
    (C) The overhead involved in process switch is same as mode switch.
    (D) comparing the overhead involved in process switch and mode switch is irrelevant.
11. Viruses, Logic bombs and Backdoors are examples of
    (A) Parasitic malware
    (B) Self-replicated malware
    (C) Self-contained malware
    (D) Active malware
12. Which of the following details will be maintained by each thread, in a multithreaded environment?
    (i) Register state (ii) Priority
    (iii) Stack
    (A) (i), (ii) (B) (ii), (iii)
    (C) (i), (iii) (D) (i), (ii) and (iii)
13. Which of the following are advantages of using User-Level-Threads (ULT) over Kernel-Level-Threads?
    (i) There is no need of kernel mode privileges for thread switching.
    (ii) ULTs can run on any OS.
    (iii) A system call cannot block the entire process.
    (A) (i), (ii) (B) (i) only
    (C) (ii), (iii) (D) (i), (iii)
14. Consider a multiprogramming environment, in which two processes are running and one process is unaware of another process, then which of the following problems will occur?
    (A) Mutual exclusion (B) Deadlock
    (C) Starvation (D) All the above.
15. Which of the following will be (a) requirement(s) for mutual exclusion?
    (A) A process remains inside its critical section for a finite time only.
    (B) A process that halts in its non critical section must do so without interfering with other processes.
    (C) When no process is in a critical section, any process that requests entry to its critical section may be permitted to enter with some delay.
    (D) Both (A) and (B)

16. Identify the correct sequence of actions from the following, to read data with a Virtual address using TLB and cache (Assume TLB and cache has miss):
(i) Access the TLB
(ii) Read from cache
(iii) Access memory to get address
(iv) Access memory to read data.
(A) (i), (ii), (iii), (iv) (B) (i), (iii), (ii), (iv)
(C) (i), (ii), (iv), (iii) (D) (i), (iii), (iv), (ii)

17. A 2-Level page translation scheme has 4 K byte pages and 4 Byte page table entries. The virtual address has 32-bits. What is the number of bits required to access first level; second level page table entries and offset in a page respectively?
(A) 9, 9, 14 (B) 12, 12, 8
(C) 10, 10, 12 (D) 8, 12, 12

18. What is the effective access time for TLB with 90% hit rate, 1 ns to access TLB and 10 ns to access memory. (Assume a 2-level page table)
(A) 1 ns (B) 2 ns
(C) 3 ns (D) 4 ns

19. Consider the page reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5. The number of page frames allocated is 3. Using FIFO, in which way, the number of page faults change by increasing the page frames allocated to 4.
(A) increases by two (B) decreases by two
(C) increases by one (D) decreases by one

20. A 512 KB file is stored contiguously on one disk track. Each track contains 1024 sectors, each sector is 512 bytes. Average seek time is 1 ms. And the rotational speed is 15000 rpm. What is the average access time to read the entire file?
(A) 2 ms (B) 4 ms
(C) 7 ms (D) 3 ms

21. Consider mapping a Virtual memory of 1 GB onto a physical memory organized into 256 page frames of 4 KB each. Assume that the smallest addressable unit is 1 byte. Then which of the following is TRUE?
I. The page table fit in the main memory
II. The frame table fit in a single page.
(A) I only (B) II only
(C) Both I and II (D) Neither I nor II

22. Consider below program segment:
```
# include < stdio.h>
# include < unistd.h>
..................
int main ()
{
pid p;
p = fork ();
if (p = = 0)
{
fork ();
fork ();
for k ():
}
return 0;
}
```
Including the initial parent process, how many processes will be created?
(A) 7 (B) 15
(C) 8 (D) 9

23. Consider the following resource requests.
P_1 requests exclusive use of both R_1 and R_2
P_2 requests exclusive use of both R_2 and R_3
P_3 requests exclusive use of both R_3 and R_4
P_4 requests exclusive use of both R_4 and R_2
Resources are assigned in process request order. (P_1 is first). Which of the following is TRUE?
(A) Given system is in deadlock.
(B) There is a possibility of deadlock after P_1 finishes its execution.
(C) There is no deadlock in given system.
(D) After P_1, if P_2 executes then there is a possibility of deadlock.

24. Which of the following instructions can only be executed in kernel mode?
(i) Load Instruction
(ii) Modify PC register
(iii) Modify SP register
(iv) Modify the register that controls kernel/user mode.
(v) Direct access to I/O device.
(A) (i), (ii), (v) (B) (i), (iii), (iv)
(C) (iv), (v) (D) (ii), (iv)

Directions for questions 25 and 26: A computer with a 32-bit address uses a 2-level page table. The virtual address format is shown below:

1st-level page table	2nd-level page table	Off set

25. What is the page size?
(A) 1024 B (B) 2048 B
(C) 4096 B (D) 8192 B

26. How many pages are there?
(A) 2^9 (B) 2^{11}
(C) 2^{12} (D) 2^{20}

27. Suppose that a 32-bit virtual address is broken up into four fields p, q, r and s. The first three are used for a 3-level page table system. The fourth field, s is the offset. Then which of the following is TRUE?
(A) The number of pages depend on the total number of bits in p, q, r combined.
(B) The number of pages depend on the total number of bits in p, q, r and s combined.
(C) The number of pages depend on the split among the fields p, q, r.
(D) The number of pages depend on the split among the fields p, q, r and s.

28. A computer provides each process with 65, 536 bytes of address space. A particular program has a text size of 32768 bytes, a data size of 16386 bytes and a stack size of 15870 bytes. If a page may not contain parts of two different segments then which of the following is TRUE?
(A) The program will fit in the address space if the page size is 4096 bytes.
(B) The program will fit in the address space if the page size is 2048 bytes.
(C) The program will fit in the address space if the page size is 1024 bytes.
(D) The program will fit in the address space if the page size is 512 bytes.

29. The Newton–Raphson method is applied to compute a root of the equation $f(x) = x^4 - x^3 - x^2 - 21x + 18 = 0$. With $x_0 = 3.1$ as the initial solution, the method converges to an exact solution after how many iterations?
(A) 1 (B) 4
(C) 7 (D) 10

30. How many disk operations are needed to fetch the inode for the file Admin/OS/UNIX/File/src.p?
Assume that the inode for this root directory is memory but nothing else along the path is in memory. (Note: All directories fit in one disk block)
(A) 5 (B) 10
(C) 4 (D) 8

31. The beginning of a free space bitmap looks like below after the disk partition is first formatted:
1000 0000 0000 0000 ....
The system always searches for free blocks starting at the lowest numbered block. So after writing file *A*, which uses 5 blocks, the bit map looks like: 1111 1100 0000 0000 Then what will be the bit map after performing following
actions:
(i) File *B* of 6 blocks is written
(ii) File *A* is deleted
(iii) File *C* of 7 blocks is written
(iv) File *B* is deleted
(A) 1111 1111 0000 0000 ....
(B) 1111 1111 1111 1100 ......
(C) 1111 1100 0000 1100 ......
(D) 1000 0000 0111 1111 ....

32. Consider below features:
(i) This scheduler has more speed.
(ii) The scheduler has less control over the degree of multiprogramming.
(iii) The scheduler is minimal in time sharing systems.
Which scheduler has above features?
(A) Long-term scheduler
(B) Medium-term scheduler
(C) Short-term scheduler
(D) None of these

33. Consider a system consisting of four processes and single resource. The current status of the Claim and Allocation matrices are:

$$C = \begin{bmatrix} 4 \\ 3 \\ 10 \\ 7 \end{bmatrix} \qquad A = \begin{bmatrix} 2 \\ 2 \\ 4 \\ 2 \end{bmatrix}$$

What is the minimum number of units of the resource(s) needed to be available for this state to be safe?
(A) 0 (B) 1
(C) 2 (D) 3

Common Data Questions 34 and 35:
Consider two CPU scheduling algorithms for a single CPU: Round Robin scheduling and Shortest job First scheduling. Consider below five processes with arrival times and expected CPU time.

Process	Arrival time	Expected CPU Time
P1	0	15
P2	3	13
P3	5	9
P4	6	5
P5	18	8

34. What is the average waiting time using SJF?
(A) 5 (B) 10
(C) 13.6 (D) 15.4

35. What is the average waiting time using Round Robin scheduling with time quantum of 6 units?
(A) 36.2 (B) 18.4
(C) 12.6 (D) 23.4

Answer Keys

1. D	**2.** A	**3.** B	**4.** B	**5.** D	**6.** A	**7.** D	**8.** D	**9.** D	**10.** B
11. A	**12.** D	**13.** A	**14.** D	**15.** D	**16.** B	**17.** C	**18.** C	**19.** C	**20.** C
21. C	**22.** D	**23.** B	**24.** C	**25.** C	**26.** D	**27.** A	**28.** D	**29.** B	**30.** B
31. C	**32.** C	**33.** B	**34.** C	**35.** D					

Hints and Explanations

1. All those services are provided by OS. Choice (D)

2. Privileged instructions will be executed in kernel mode, in which protected areas of memory will be accessed. Choice (A)

3. In Uniprogramming, the memory holds only a single program. In multiprogram, the CPU executes more than one program in time interleaved fashion, which are present in memory. In multiprocessing, There will be more than one CPU executing more than one program. Choice (B)

4. The Time sharing system handles multiple interactive jobs, so that response time will be reduced. Choice (B)

5. PCB holds information about a process. Choice (D)

7. A process will be in blocked state if it is waiting for an event to occur. Choice (D)

10. Mode switch occurs without changing the state of process. Process switch requires some changes in its environment.

∴ Overhead of process switch is greater than mode switch. Choice (B)

11. In Parasitic malware, the fragments of programs do not exist independently Choice (A)

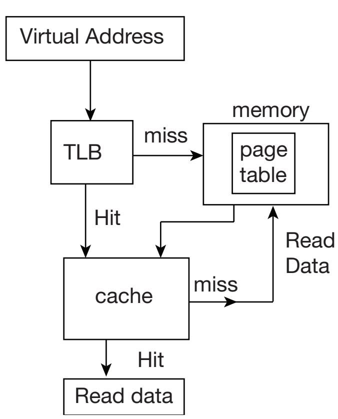
12. In multithreaded environment, each thread maintains a stack, register values, priority and other thread related state information. Choice (D)

13. In ULTs, the thread management will be done by thread library. So no need of kenel mode privileges for thread switching. On any OS, ULTs can run. A system call blocks entire process. Choice (A)

14. If processes are unaware of each other then competition exist between them. There is a possibility of Mutual exclusion, Deadlock and Starvation. Choice (D)

15. There will be no delay in permitting a process to enter its critical section if no process is in critical section. Choice (D)

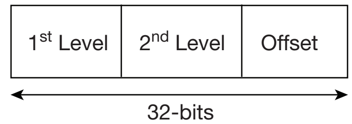
16.



So the sequence of actions will be (i), (iii), (ii), (iv) Choice (B)

17. Page size = 4 KB = 2^{12} B.

⇒ 12-bits required to identify a byte in a page.



Number of entries in 2nd level Page table $= \frac{2^{12}}{4} = 2^{10}$

∴ 10 bits required for 2nd level. Similarly for first level also 10-bits required. Choice (C)

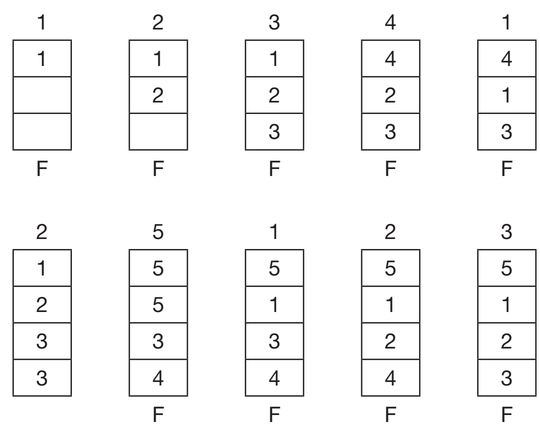
18. Effective TLB access time

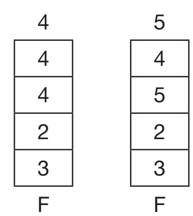
= hit ratio * TLB access time + (1-hit ratio) * (TLB access time + memory access time *2)

= 0.9 * 1 + (0.1) * (1 + 20) = 0.9 + 2.1 = 3 ns.

Choice (C)

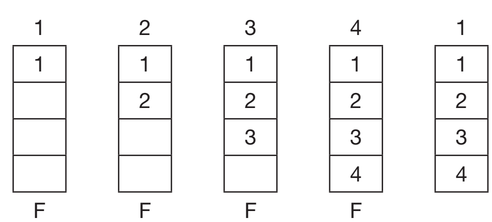
19. Initially, page frames allocated = 3





∴ Number of page faults = 9

Page frames Allocated = 4



2	5	1	2	3
1	5	5	5	5
2	2	1	1	1
3	3	3	2	2
4	4	4	4	3
	F	F	F	F

4	5
4	4
1	5
2	2
3	3
F	F

∴ Number of page faults = 10

∴ Number of page fault increases by one. Choice (C)

20. Seek time = 1 ms

Rotational speed = 15000 RPM.

15000 RPM = 15000/60 RPS = 250 rps

Rotational delay $= \dfrac{1}{2\times 250} = 2$ ms

Transfer time $= \dfrac{512\times 1024}{250\times 1024\times 512} = 4$ ms

∴ Total time = seek time + Rotational delay + Transfer time = 7 ms Choice (C)

21. Virtual memory = 1 GB = 2^{30} B

Page frames = 256

Page size = 4 KB

Physical memory = 256 * 4 K = 2^{20} B.

Number of pages $= \dfrac{2^{30}}{2^{12}} = 2^{18}$

Page table size will fit in main memory. (main memory = 2^{20} B, Page table size = 2^{18} * PTE,

PTE will be less than 4 B)

∴ I is true

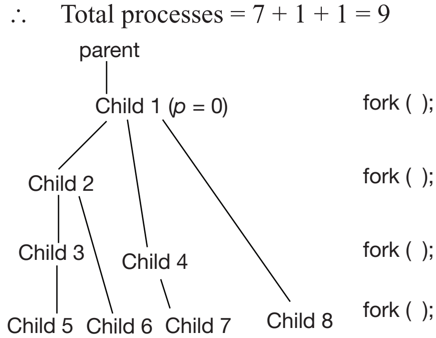
Frame table size = 256 * (8 + 18) = 6656 bits

This can fit in a page.

∴ It is true. Choice (C)

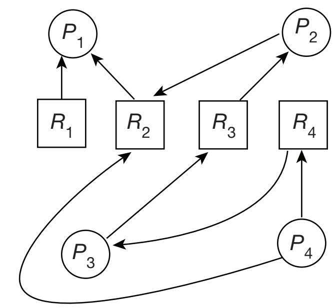
22. Fork () is used to create a child process *A* parent process returns the id of its children. A child process returns zero The first fork () call creates a child process. Only for child process $p = 0$, so child process only executes 3 fork() call statements, which creates 7 child processes.

∴ Total processes = 7 + 1 + 1 = 9



Choice (D)

23. The resource allocation graph of given system is shown below:



Initially P_1 completes and releases its resources. Now if P_4 acquires R_2, then P_2 waits for R_2, P_4 waits for R_4, P_3 waits for R_3. There is a circular wait. But if P_2 acquires R_2 then there will be no deadlock. Choice (B)

24. Load, modify *PC*, *SP* are not protected instructions. Modifying the register that controls kernel/user mode is a protected instruction. Otherwise any process can make itself run in kernel mode. I/O devices are only directly accessible by the *OS*. Choice (C)

25. Offset = 12 bits

Using 12-bits, we can access 2^{12} bytes. So the page size is 2^{12} = 4096 bytes. Choice (C)

26. Number of pages $= \dfrac{\text{Virtual memory}}{\text{Page size}}$

Number of pages $= \dfrac{2^{32}}{2^{12}} = 2^{20}$ Choice (D)

27. The number of pages depend on $p + q + r$. Choice (A)

28. Given total address space = 65536 bytes

Text size = 32768 bytes

Data size = 16386 bytes

Stack size = 15870 bytes

If page size = 4096

Total pages in memory $= \dfrac{65536}{4096} = 16$

Pages for text $= \dfrac{32768}{4096} = 8$

Pages for data $= \dfrac{16386}{4096} = 5$

Pages for stack $= \dfrac{15870}{4096} = 4$

Total pages required for process = 8 + 5 + 4 = 17

∴ Choice (A) is wrong.

Similarly if page size is 2048, the memory consists of 32 pages. If page size is 1024, the memory consists of 64 pages, but process requires 65 pages.

If page size = 512 bytes,

Memory consists of 128 pages and process requires 128 pages.

∴ Choice (D) is correct Choice (D)

29. The iterative formula for finding root of $f(x) = 0$ in Newton–Raphson method is

$$x_{k+1} = x_k - \frac{f(x_k)}{f'(x_k)}$$

By using this formula, starting with $k = 0$ and $x_0 = 3.1$, it can be easily observed that $x_4 = 3$ (the exact root)

$\therefore$ After 4 iterations, the method converges to exact root. Choice (B)

30. As all directories fit in one disk block, then all required data on a directory is stored in the inode itself.

To open /Admin/OS/UNIX/file/src.p

We do following reads:

1. inode of /→ Already in memory
2. Directory for /
3. inode of /Admin
4. Directory of /Admin
5. inode of /Admin/OS
6. Directory of /Admin/OS
7. inode of /Admin/OS/UNIX
8. Directory of /Admin/ OS/UNIX/File
9. inode of /Admin/OS/UNIX/File
10. Directory of /Admin/ OS/UNIX/File
11. inode of /Admin/OS/UNIX/file /scr.p

$\therefore$ 10-disk read operations required. Choice (B)

31. Bitmap after writing A is

1111 1100 0000 0000 …..

File B (6 Blocks): $\underbrace{1111\ 11}_{A}\ \underbrace{11\ 1111}_{B}\ 0000$ .....

Delete A : 1000 0011 1111 0000 ……

File C (7 blocks): $\underbrace{1111\ 11}_{C}\ \underbrace{11\ 1111}_{B}\ \underbrace{1}_{C}100$ .....

Delete B: $\underbrace{1\,111\ 11}_{C}\ 000000\ \underbrace{1}_{C}10$ .....

$\therefore$ Final bitmap : 1111 1100 0000 1100 ... Choice (C)

32. A short-term scheduler selects the process which is ready to execute. It does not have that much of control over degree of multiprogramming Choice (C)

33.

$$\text{Allocation} = \begin{array}{c} p_1 \\ p_2 \\ p_3 \\ p_4 \end{array}\begin{bmatrix} 2 \\ 2 \\ 4 \\ 2 \end{bmatrix}$$

Total resources (R) = 10, Available (V) = 0

Need 1 more additional resource for execution of P_2.

$\Rightarrow$ $R = 11$, $V = 1$

Now p_2 can complete. And it releases its allocted resources.

$\Rightarrow$ $R = 11$, $V = 3$

p_1 requires 2 more resources. After execution it releases those 2 + allocated resources i.e., 4

$\Rightarrow$ $R = 11$, $V = 5$

Now p_4 can execute with the available and allocated resources.

$\Rightarrow$ $R = 11$, $V = 7$

Now p_3 can execute.

$\therefore$ One additional resource required.

Choice (B)

34. Shortest-job-First algorithm will select the shortest CPU burst time first.

P_1	P_4	P_5	P_3	P_2

0 15 20 28 37 50

Waiting time of $P_1 = 0$

Waiting time of $P_2 = 37 - 3 = 34$

Waiting time of $P_3 = 28 - 5 = 23$

Waiting time of $P_4 = 15 - 6 = 9$

Waiting time of $P_5 = 20 - 18 = 2$

$$\therefore \quad \text{Average waiting time } = \frac{(0+34+23+9+2)}{5}$$

$= 13.6$ units

Choice (C)

35. In Round Robin algorithm with time quantum 6 units, each job executed for 6 units and wait in waiting queue. The job with more waiting time will be executed first.

P_1	P_2	P_3	P_4	P_1	

0 6 12 18 23 29

P_2	P_5	P_3	P_1	P_5	

35 41 44 47 49

Waiting time of $P_2 = (6 - 3\ ) + (29 - 12) = 20$

Waiting time of $P_3 = (12 - 5\ ) + (41 - 18) = 30$

Waiting time of $P_4 = (18 - 6) = 12$

Waiting time of $P_5 = (\ 35 - 18) + (47 - 41) = 23$

$$\text{Average waiting time } = \frac{32+20+30+12+23}{5} = 23.4$$

Choice (D)

OPERATING SYSTEMS TEST 2

Number of Questions: 35 **Section Marks: 30**

Directions for questions 1 to 35: Select the correct alternative from the given choices

1. Suppose we have variable logical records of length 10 bytes, 20 bytes and 30 bytes, while the physical block size in disk is 15 bytes. What is the maximum and minimum fragmentation seen in bytes?
(A) 10 and 5 (B) 10 and 0
(C) 5 and 0 (D) 5 and 5

2. Match the following:

List-A	List-B
1. Contiguous allocation policy	(i) Internal fragmentation
2. Chained list allocation	(ii) External Fragmentation
3. Indexed allocation	

(A) 1–(i), 2–(i), 3–(i) (B) 1–(i), 2–(i), 3–(ii)
(C) 1–(ii), 2–(i), 3–(i) (D) 1–(ii), 2–(ii), 3–(i)

3. Suppose that the scheduling algorithm favors those processes that have used the least processor time in the recent past. Then which of the following is TRUE?
(A) The algorithm favors I/O bound programs.
(B) The algorithm favors CPU bound programs.
(C) Fair treatment to all the programs.
(D) The algorithm favors longer programs.

4. Which of the following is not a necessary condition for deadlock?
(A) Mutual exclusion (B) Hold and wait
(C) Circular wait (D) Reentrancy

5. What will be the state of a process after it encounters an I/O instruction?
(A) Ready (B) Blocked
(C) Idle (D) Running

6. Which of the following is used by a program to request a service from an operating system's kernel that it does not normally have permission to run?
(A) Context switch (B) Threads
(C) System call (D) Service call

7. Which of the following is the reason for having threads within a process?
(i) Threads are lighter in weight than processes.
(ii) Threads have high performance when the processes have both I/O and CPU activity.
(iii) Threads are useful on systems with multiple CPU's.
(A) (i), (ii) (B) (ii), (iii)
(C) (i), (iii) (D) (i), (ii), (iii)

8. Which of the following is TRUE?
(A) No protection required between threads.
(B) Different threads in a process are always independent.
(C) All the threads cannot share open files, child processes.
(D) Each thread will maintain Accounting Information.

9. Which of the following is FALSE with respect to a monitor?
(A) Only one process can be active in a monitor at any instant.
(B) A monitor is a collection of procedures.
(C) Procedures declared outside the monitor can access monitor's internal data structure.
(D) Monitors can be used to provide mutual exclusion.

10. Which of the following is a reason for process scheduling?
(i) When a new process is created.
(ii) When a process exits.
(iii) When a process blocks.
(iv) When an interrupt occurs.
(A) (i), (ii) (B) (i), (iii), (iv)
(C) (ii), (iii) (D) (i), (ii), (iii), (iv)

11. Match the following:

List-A	List-B
1. First Come First Serve	I. High throughput
2. Shortest Process Next	II. Fair treatment of processes
3. Round Robin	III. Non-preemptive

(A) 1-II, 2-III, 3-II (B) 1-III, 2-I, 3-II
(C) 1-I, 2-III, 3-II (D) 1-I, 2-II, 3-III

12. To use process switching in hardware, instead of interrupts, the CPU needs to know about
(A) Process table data structure
(B) System calls
(C) CPU burst time
(D) PC only

13. Which of the following is FALSE?
(A) Throughput is the number of processes that complete their execution per unit time.
(B) Turnaround time is the amount of time required to execute a particular process.
(C) Waiting time is the amount of time, a process has been waiting in the ready queue.
(D) Response time is the amount of time taken to get the output.

14. Which of the following scheduling algorithm is also referred as preemptive version of FCFS?
(A) Shortest Job First
(B) Round Robin
(C) Shortest Remaining Time First
(D) None of these

15. Which of the following malware can result in pop-up ads or can redirect a browser to a commercial site?
(A) Spyware (B) Adware
(C) Zombie (D) Backdoor

16. In 48-bit machine, with 4 GB RAM and 8 KB page size, how many entries will be there in the page table if it is inverted?
(A) 2^{35} (B) 2^{20}
(C) 2^{19} (D) 2^{13}

17. Consider the following process and resource requirement of each process.

Process	Resource 1		Resource 2	
	Used	Max	Used	Max
P1	2	3	2	4
P2	2	4	2	3
P3	3	5	2	5

Assume that there are a total of 8 instances of resource type 1 and 7 instances of resource type 2. What is the state of this system?
(A) Can go to safe or unsafe state based on sequence.
(B) Safe state
(C) Unsafe state
(D) Deadlock state

18. Consider a system that has two CPU's and each CPU has two threads. Suppose three programs *P*1, *P*2 and *P*3 are started with run times 10, 15 and 25 ms respectively. What is the minimum time required to complete the execution of these programs?
(A) 25 ms (B) 35 ms
(C) 45 ms (D) 40 ms

19. A computer system has enough room to hold five programs in its main memory. These programs are blocked on I/O, half the time. What fraction of the CPU time is wasted?
(A) 96.8% (B) 32%
(C) 3.125% (D) 50%

20. A computer has 4 GB of RAM, of which the operating system occupies 256 MB. The processes are all 128 MB and have the same characteristics. If the goal is 95% CPU utilization, what is the maximum I/O wait that can be tolerated?
(A) 90.4% (B) 85.4%
(C) 72% (D) 50%

21. A file system with 4 KB blocks can access 64 GB worth of data through an i-node triple indirect block.
How many bits does the file system use for block pointers?
(A) 8 (B) 16
(C) 32 (D) 64

22. In a File Allocation table, each entry is of size 24-bits. For a 32 GB disk, what is the minimum size of a file allocation in this system?
(A) 1 KB (B) 2 KB
(C) 4 KB (D) 8 KB

23. On a system with 2^{64} bytes of memory and fixed partitions with a partition size of 2^{20} bytes, what is the minimum number of bits needed in an entry in the process table to record the partition to which a process has been allocated?
(A) 20-bits (B) 32-bits
(C) 36-bits (D) 44-bits

24. Which of the following features are required by an ideal CPU scheduling algorithm?
(i) Maximize the CPU utilization
(ii) Maximize the throughput
(iii) Minimize the turnaround time
(iv) Minimize the waiting time
(v) Minimize the response time
(A) (i), (iii), (v) (B) (ii), (iv), (v)
(C) (i), (ii), (iv), (v) (D) (i), (ii), (iii), (iv), (v)

25. Consider the following set of processes:

Process	Burst time	Priority
P1	10	3
P2	1	1
P3	2	3
P4	1	4
P5	5	2

The processes are assumed to have arrived in the order *P*1, *P*2, *P*3, *P*4 and *P*5 all at time 0. What is the average Turnaround time using Shortest Job First scheduling?
(A) 5 (B) 7
(C) 15 (D) 19

26. Consider the given concurrent processes:

```
Process P0:
while (true)
{
    while(turn = = 1);
    critical section
    turn = 1
    remainder section
}
Process P1:
    while (true)
{
        while (turn = = 0);
            critical section
        turn = 0
        remainder section
}
```

'turn' is a global Boolean variable, Which will take either 0 or 1. Which of the following is TRUE for above two processes?
(A) There is mutual exclusion and progress.
(B) There is progress but no mutual exclusion

(C) There is mutual exclusion but no progress.
(D) There is no mutual exclusion and no progress.

27. Consider 'n' concurrent processes P_1, P_2, ... P_n whose code is shown below:

```
var mutex : semaphore
mutex = 1;
process Pi:
    Repeat
        wait (mutex);
            critical section
        signal (mutex);
            Remainder section
        until false;
```

Then which of the following is TRUE?
(A) There is mutual exclusion.
(B) There is no mutual exclusion in the system.
(C) There is a deadlock in the system
(D) Both (B) and (C)

28. Which of the following correctly specifies the 'wait' operation of a counting semaphore?
(A) semvalue = semvalue – 1;
if semvalue < 0 then
Add this process to Blocked queue.
(B) semvalue = semvalue + 1 ;
if semvalue ≤ 0 then
Block the process;
(C) semvalue = semvalue – 1;
if semvalue ≤ 0 then
Block the process;
(D) semvalue = semvalue – 1;
if semvalue < 1 then Block the process

29. Identify the TRUE statements from the following:
(i) Logical address is generated by the CPU.
(ii) Physical address is the address seen by the memory unit.
(iii) The user program always deals with physical address.
(A) (i), (ii) (B) (i), (iii)
(C) (ii), (iii) (D) (i), (ii), (iii)

30. The correct sequence of steps required for page fault handling from the following is:
(i) Search in the page table.
(ii) Search for the page in the backing store.
(iii) Reset page table
(iv) Bring in missing page
(v) Restart instruction
(vi) The OS takes control on trap.
(A) (i), (ii), (iv), (v), (vi), (iii)
(B) (ii), (i), (v), (iv), (iii), (vi)
(C) (i), (vi), (ii), (iv), (v), (iii)
(D) (i), (vi), (ii), (iv), (iii), (v)

31. If the multiprogramming level increases rapidly then the processor utilization:
(A) always increases (B) always decreases
(C) decreases some times (D) doesn't effected

Common Data for Questions 32 and 33

Consider a swapping system in which memory consists of the following hole sizes in order: 11 KB, 5 KB, 21 KB, 19 KB, 8 KB, 10 KB, 13 KB and 16 KB.

32. Which hole is taken for successive segment requests 13 KB, 11 KB and 10 KB for First-fit?
(A) 13 KB, 11 KB, 10 KB (B) 21 KB, 11 KB, 19 KB
(C) 11 KB, 5 KB, 21 KB (D) 13 KB, 16 KB, 11 KB

33. Which hole is taken for successive segment requests 12 KB, 10 KB, 9 KB for Best-fit?
(A) 21 KB, 19 KB, 11 KB (B) 13 KB, 16 KB, 11 KB
(C) 13 KB, 10 KB, 11 KB (D) 13 KB, 11 KB, 10 KB

Common Data for Questions 34 and 35

A computer has four page frames. The time of loading, time of last access and modify (M) bits of each page are shown as below.

Page	Load Time	Last access time	M
0	149	198	1
1	255	280	0
2	85	293	0
3	129	285	1

34. Which page will FIFO algorithm replace next?
(A) page 0 (B) page 1
(C) page 2 (D) page 3

35. Which page will LRU algorithm replace next?
(A) page 0 (B) page 1
(C) page 2 (D) page 3

Answer Keys

1. B	**2.** C	**3.** A	**4.** D	**5.** B	**6.** C	**7.** D	**8.** A	**9.** C	**10.** D

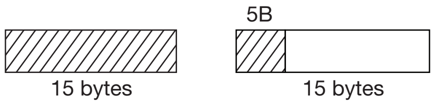
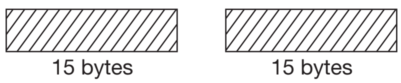
Hints and Explanations

1. Record lengths are 10, 20, 30 Bytes
Physical block size = 15 bytes.
Maximum fragmentation occurs with 20 byte records.



$\therefore$ Maximum fragmentation = 10 bytes
Minimum fragmentation occurs with 30 byte records.



$\therefore$ Minimum fragmentation = 0 Bytes. Choice (B)

2. In Contiguous file Allocation, each file occupies a set of contiguous blocks on the disk. It suffers from external fragmentation. In linked and indexed allocation, there is internal fragmentation. Choice (C)

3. The algorithm favors I/O bound programs because of the relatively short CPU burst request by them. Choice (A)

4. The necessary and sufficient conditions for deadlock are Mutual exclusion, Hold-and-wait, No-preemption and Circular wait. Choice (D)

5. During I/O instruction execution, a process will be in 'Blocked' state. Choice (B)

6. A system call is used to get services of OS's kernel. Choice (C)

8. No protection is required between threads. (As it is impossible and not necessary). Threads are dependent on each other. Threads can share open files and child processes. Accounting information is maintained by process. Choice (A)

9. Procedures declared outside the monitor can't access monitor's internal data. Choice (C)

10. All the four are reasons for process scheduling. Choice (D)

11. FCFS, SPN both are non-preemptive. FCFS's throughput is not that much emphasized. It also penalizes short processes. SPN penalizes long processes. Its throughput is high. Round Robin is preemptive and it treats all processes fairly. Choice (B)

12. To use process switching, the CPU needs to know about process table and state. Choice (A)

13. Response time is the amount of time it takes from, when a request was submitted until the first response is produced. Choice (D)

14. Round Robin is the preemptive version of FCFS. Choice (B)

15. Advertising that is integrated into software is adware. Choice (B)

16. In inverted page table, the number of entries is the number of frames in the main memory.
Main memory capacity = 4 GB = 2^{32}B
Page size = frame size = 8 KB = 2^{13}B

$\therefore$ Number of entries $= \dfrac{2^{32}}{2^{13}} = 2^{19}$ Choice (C)

17. Total resources $(R) = \begin{bmatrix} R_1 \\ R_2 \end{bmatrix} = \begin{bmatrix} 8 \\ 7 \end{bmatrix}$

Total used resources $= \begin{bmatrix} 7 \\ 6 \end{bmatrix}$

Available resources$(V) = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$

$P1$ requires (1, 2) resources.
$P2$ requires (2, 1) resources.
$P3$ requires (2, 3) resources.
No process can execute with available resources.
So the system is in deadlock. Choice (D)

18. On one CPU, at a time only one program will be executed. At a time two programs will be in running state. If $P1$, $P2$ are executed on CPU1 and $P3$ executed on another CPU, the execution time will be 25 ms. Choice (A)

19. CPU utilization = $1 - p^n$
where n is the degree of multiprogramming and 'p' is the fraction of time a process spends waiting for I/O.
Here $n = 5$

$p = \dfrac{1}{2}$

$\therefore$ CPU time wasted $= \left(\dfrac{1}{2}\right)^5 = \dfrac{1}{32} 0.03125 = 3.125\%$

Choice (C)

20. RAM capacity = 4 GB = 2^{32} B
OS capacity = 256 MB = 2^{28}B
Remaining = $2^{32} - 2^{28} = 4026531840$
Process capacity = 128 MB = 2^{27}B
$\therefore$ Number of processes fit in remaining space

$= \dfrac{4026531840}{2^{27}} = 30$

30 processes can be placed in memory at a time.
Let 'P' is the probability that a process has an I/O.
If all the 30 processes are in I/O, the probability is P^{30}.
CPU idle percentage = 5%
By equating both,
$P^{30} = 0.05 \Rightarrow P = 0.904$
So we can tolerate processes with upto 90.4% I/O. Choice (A)

21. Data accessed using inode triple indirect block = 64 GB
Block size = 4 KB
$(\text{Number of blocks})^3 \times$ block size
= Data accessed using triple indirect blocks
$(\text{Number of blocks})^3 \times 4\text{ K} = 64\text{ G}$

$\Rightarrow \quad (\text{Number of blocks})^3 = \dfrac{2^{36}}{2^{12}}$

$\Rightarrow \quad$ Number of blocks $= 2^8$

$\therefore \quad$ Bits required for block pointer = 8-bits

Choice (A)

22. Disk capacity = 32 GB = 2^{35}B
Each entry size = 24-bits
Using 24-bits, we can access 2^{24} B.
$\therefore \quad$ Minimum size of a file allocation

$= \dfrac{2^{35}}{2^{24}} = 2^{11}\text{B} = 2\text{ KB}$ Choice (B)

23. Memory = 2^{64}B
Partition size = 2^{20}B

Number of partitions $= \dfrac{2^{64}}{2^{20}} = 2^{44}$

$\therefore \quad$ 44-bits required for an entry in the process table.

Choice (D)

24. All those features are required by an ideal algorithm.

Choice (D)

25. In SJF the job with smallest CPU burst will execute first. The Gantt chart for given processes is shown below:

P2	P4	P3	P5	P1

0 1 2 4 9 19

Turn Around Time (TAT) of $P1$ = 19 (waiting time + CPU burst)
TAT of $P2$ = 1
TAT of $P3$ = 4
TAT of $P4$ = 2
TAT of $P5$ = 9

Average TAT $= \dfrac{19 + 1 + 4 + 2 + 9}{5} = \dfrac{35}{5} = 7$ units

Choice (B)

26. Initially 'turn = 0' then P_0 only can enter the critical section and if P_1 tries to enter, it is not possible to enter critical section.
Only one process can enter critical section. So there is mutual exclusion. But there is no progress. ($\because$ A process cannot be able to enter into critical section even if no process is in critical section). Choice (C)

27. Only one process can enter the critical section at a time. So there is mutual exclusion. Choice (A)

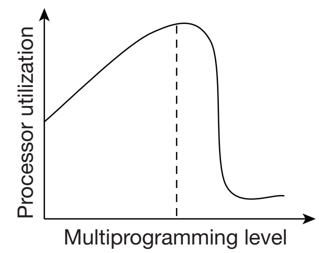
28. The wait operation decrements the semaphore value. If it is less than zero, block the process. Choice (A)

29. User program deals with logical address.

Choice (A)

30. Page fault occurs when the page for which CPU is searching is not in memory. Initially we search in the page table. If it is a trap, the OS takes the control. OS searches the backing store for the required page and places it in memory. Updates the page table and restarts the instruction. Choice (D)

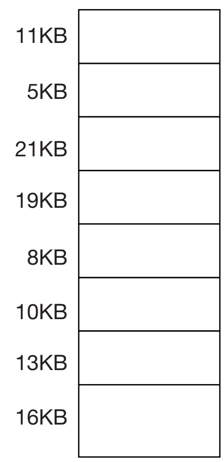
31. If the multiprogramming level increases from a small value, then the processor utilization rises.
But from a point onwards, the number of page faults rises dramatically and processor utilization collapses. The graph is shown below.



Choice (C)

Common Data for Questions 32 and 33

32. Memory system with given hole sizes is shown below:



In first-fit policy, choose the hole from beginning of the memory, using which given request is satisfied.
13 KB placed in 21 KB.
11 KB placed in 11 KB.
10 KB placed in 19 KB. Choice (B)

33. Best-fit policy searches for all holes in the memory and selects the smallest hole using which the memory request will be satisfied.
12 KB placed in 13 KB
10 KB placed in 10 KB
9 KB placed in 11 KB Choice (C)

34. FIFO will replace the page which entered first into the memory.
Load time of page 2 is least
$\therefore \quad$ FIFO replaces page 2. Choice (C)

35. LRU replaces the page whose access time is least.
Access time of page 0 is least. So LRU replaces page 0.
Choice (A)

Operating Systems Test 3

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Round Robin scheduling with large time slice behaves as:
   (A) FCFS
   (B) Priority based scheduling
   (C) Multi-level queue scheduling
   (D) Preemptive SJF

2. Priority inversion means:
   (A) Shortest Job waits for longest job
   (B) High priority process waits for low priority process
   (C) Longest job waits for shortest job
   (D) both (A) and (C).

3. Consider the following table with 4 processes:

Process	Arrived Time	Burst Time
P1	0	5
P2	1	4
P3	2	2
P4	3	3

   If Longest Remaining Time scheduling (Preemptive longest Job First) is used, then the average turnaround time is ______.
   (A) 11 (B) 12
   (C) 13 (D) 14

4. Consider the following table:

Process	Arrival Time	Burst Time
P0	0	4
P1	1	3
P2	1	3
P3	2	5

   If Longest Job First scheduling is used then the average waiting time is ______.
   (A) 5.00 (B) 5.25
   (C) 5.50 (D) 5.75

5. Consider the following table:

Process	Arrival Time	Turn around Time
P0	0	15
P1	0	2
P2	0	18
P3	0	20
P4	0	7

   If priority scheduling is used for scheduling, what is the burst time of process P_o?
   (A) 15 (B) 13
   (C) 8 (D) 3

6. As the time quantum increases for Round Robin scheduling, generally the average waiting time:
   (A) Increases
   (B) Decreases
   (C) Unchanged
   (D) Cannot be determined

7. Consider three processes $P0$, $P1$, $P2$ arrived at Time 0, with the burst times x, y, z respectively. $x < z < y$. What is the average waiting, if SJF is used for scheduling?
   (A) $\frac{x+y+z}{2}$ (B) $\frac{x+z}{3}$
   (C) $\frac{2x+z}{3}$ (D) $\frac{x+z+y}{3}$

8. Consider the following table:

Process	Arrival Time	Burst Time
P0	0	8
P1	1	4
P2	2	2

   What is average waiting time of processes which have taken more than one slot for completion, When SRTF is used for scheduling?
   (A) 2.66 (B) 3.0
   (C) 4.0 (D) 3.33

9. Match the following:

List 1		List 2	
(a)	Ready → Running	1.	Dispatching
(b)	Running → Waiting	2.	Preemption
(c)	Waiting → Ready	3	Completion
(d)	Running → Terminate	4.	I/O Request
(e)	Running → Ready	5	Event occurred

	a	b	c	d	e
(A)	1	2	3	4	5
(B)	1	4	5	3	2
(C)	1	4	2	3	5
(D)	1	2	5	4	3

10. Consider the following:

Process	Arrival Time	Burst Time
A	0	4
B	1	6
C	5	3
D	7	2

   What is the waiting time of process D, if FIFO scheduling is used?

(A) 3 (B) 2
(C) 6 (D) 12

11. Preemptive scheduling takes place when ______.
(I) process switches from Running to Ready
(II) process switches from Waiting to Ready
(III) process switches from Running to waiting
(IV) process terminates
(A) I, II (B) I, II, IV
(C) I, II, III (D) I, II, III and IV

12. Blocking and Non-blocking message passing is also known as:
(A) Synchronous and Asynchronous
(B) Direct and Indirect
(C) Limited Buffer and Zero buffer
(D) Pipes and FIFO

13. Number of child processes created for the following code segment is ______.

```
fork();
fork();
fork();
fork();
```

(A) 4 (B) 8
(C) 15 (D) 16

14. Which of the following statements are TRUE about threads?
I. Thread library provides support to both user and kernel level threads.
II. Threads improves the Responsiveness and Resource sharing.
III. Kernel level thread switching is faster than user level switching.
IV. User level thread maintenance is faster than kernel level threads.
(A) I and III (B) II and IV
(C) II and III (D) I, II and III

15. Match the following:

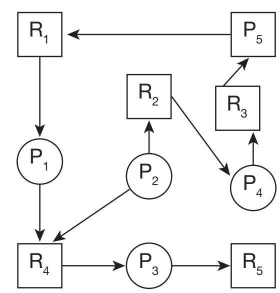
	List 1		List 2
P.	Starvation	1.	FCFS
Q.	Ageing	2.	Round Robin
R.	Context switching overhead	3.	Preemptive Priority
S.	Batch processing	4.	Highest Response Ratio next

	P	Q	R	S
(A)	1	4	2	3
(B)	4	1	3	2
(C)	3	4	2	1
(D)	1	4	3	2

16. Consider a system with four processes *A*, *B*, *C* and *D* and '*m*' instances of resource '*r*'. The resource requirements are 5, 7, 3 and 4 instances of resource '*r*' respectively. What is the minimum value of '*m*', hence system is dead lock free?
(A) 7 (B) 16
(C) 19 (D) 15

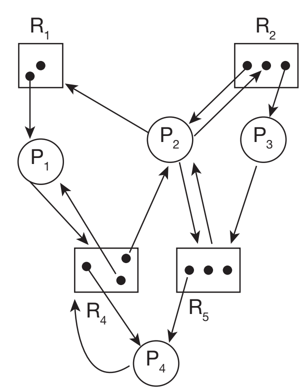
17. Which of the following system state may lead to deadlock? Let the system contains '*r*' instances of resources with '*n*' processes.
(Resource requests of each process represented in sets)
(A) $n = 5, r = 20, \{5, 5, 5, 5, 5\}$
(B) $n = 5, r = 20, \{5, 5, 4, 5, 5\}$
(C) $n = 6, r = 26, \{6, 6, 4, 3, 3, 2\}$
(D) $n = 6, r = 26, \{6, 6, 4, 3, 3, 3\}$

18. Consider the following Resource allocation Graph:



Which of the following cycle exist in it's equivalent wait-for-Graph?
(A) $P1 \rightarrow P2 \rightarrow P3 \rightarrow P4 \rightarrow P5 \rightarrow P1$
(B) $P1 \rightarrow P2 \rightarrow P3 \rightarrow P5 \rightarrow P1$
(C) $P1 \rightarrow P3 \rightarrow P4 \rightarrow P5 \rightarrow P1$
(D) $P2 \rightarrow P3 \rightarrow P4 \rightarrow P5 \rightarrow P1 \rightarrow P2$

19. Consider the following Resource allocation graph:



Which of the following dead lock cycle occurs in the given graph?
(A) $P_2 \rightarrow P_3 \rightarrow P_2$ (B) $P_2 \rightarrow P_1 \rightarrow P_4 \rightarrow P_2$
(C) Both (A) and (B) (D) None of the above

20. A counting semaphore has a value—a at a certain time, it represents:
(A) '*a*' number of processes waiting
(B) '*a*' number of process in critical section
(C) Either (A) or (B)
(D) None, negative values are not allowed on Counting semaphore

21. Semaphores ______.
(A) are process synchronization tools to avoid deadlock.

(B) are process synchronization tools to avoid race condition.
(C) uses Test And Set for synchronization.
(D) All the above

22. The system is running with 5 processes. Consider the following code segments for synchronization:

```
process 1:
while(1)
{
signal (mutex);
<Critical Section; >
signal (mutex);
}
Process i where i = 2,3,4,5.
while (1)
{
wait (mutex);
< Critical Section >
signal (mutex);
}
```

'mutex' is a binary semaphore.
Atmost how many processes can enter into the critical section?

(A) 1 (B) 2
(C) 3 (D) 5

23. Let $P0$ and $P1$ are two processes, each accesses two binary semaphores $s1$ and $s2$ to enter critical section. $s1$ and $s2$ are initialized to 1.

P_0:	P_1:
X;	W;
<critical section>	<critical section>
Y;	Z;

Consider the following code segments:

I.	wait ($s1$);	wait ($s2$);
II.	wait ($s2$);	wait ($s1$);
III.	signal ($s1$);	signal ($s2$);
IV.	signal ($s2$);	signal ($s1$);

Which of the following may lead to deadlock?

	X	Y	W	Z
(A)	I	III	II	IV
(B)	I	III	I	III
(C)	II	IV	II	IV
(D)	I	III	I	IV

24. Consider the following snapshot of a system:

	Max			Allocation		
Process	R_1	R_2	R_3	R_1	R_2	R_3
a	3	2	4	1	1	1
b	5	5	2	2	3	2
c	4	4	3	3	1	1
d	3	4	4	1	0	1

Available = {5, 3, 2}
Which of the following is not a safe sequence?

(A) *a b c d* (B) *b c d a*
(C) *b a c d* (D) *c a d b*

25. In the above system, if process 'A' requests for {0, 1, 2} resources and if the request is granted, then the system state is ______.

(A) safe state
(B) unsafe state
(C) deadlock
(D) either (B) or (C)

Answer Keys

1. A **2.** B **3.** A **4.** B **5.** C **6.** A **7.** C **8.** C **9.** B **10.** C
11. D **12.** A **13.** C **14.** B **15.** C **16.** B **17.** A **18.** C **19.** D **20.** A
21. B **22.** D **23.** A **24.** A **25.** A

Hints and Explanations

1. Choice (A)

2. Choice (B)

3.

P_1	P_1	P_2	P_1	P_2	P_4	P_1	P_2	P_3	P_4	P_1	P_2	P_3	P_4

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14

Process	AT	CT	TAT
P_1	0	11	11
P_2	1	12	11
P_3	2	13	11
P_4	3	14	11

$$\text{Average TAT } = \frac{11+11+11+11}{4} = 11$$ Choice (A)

4.

0 4 9 12 15

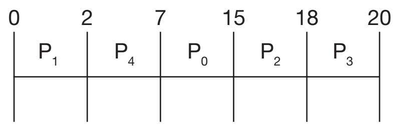
P_0	P_3	P_1	P_2

Process	AT	BT	CT	TAT	WT
P_0	0	4	4	4	0
P_1	1	3	12	11	8
P_2	1	3	15	14	11
P_3	2	5	9	7	2

Average $WT = \dfrac{(0+8+11+2)}{4} = \dfrac{21}{4} = 5.25$

Choice (B)

5. Gantt Chart:



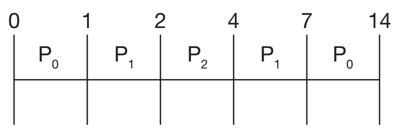
Waiting Time of P_0 is 7.

$BT = TAT - WT = 15 - 7 = 8$ Choice (C)

6. Choice (A)

7. Choice (C)

8.



Process	AT	TAT	WT
P_0	0	14	6
P_1	1	6	2
P_2	2	2	0

Processes P_0 and P_1 executed in multiple slots.

Hence average waiting time of (P_0 and P_1) $= \dfrac{6+2}{2} = 4$

Choice (C)

9. Choice (B)

10. Processes 'D' schedules at time 13.

Waiting Time = 13 – 7 (AT) = 6 Choice (C)

11. Choice (D)

12. Choice (A)

13. Choice (C)

14. Choice (B)

15. Choice (C)

16. **<u>Method 1:</u>**

Each process requirement is S_i for process 'i'.

i	–	A	B	C	D
S_i	–	5	7	3	4

Assume for each process i, $(S_i - 1)$ resources are allocated.

A	B	C	D	
4	6	2	3	allocated

This system state result in deadlock i.e., the system with ≤15 resources may lead to deadlock.

If atleast one extra resource available in this state, the system becomes deadlock free.

∴ 16 resources required.

<u>Method 2:</u>

$$\sum_{i=1}^{n} S_i < (m+n)$$

S_i – resources required for process 'i'.

m – number of resources in system

n – number of process in system.

$(5+7+3+4) < m+4 \Rightarrow m = 16$ Choice (B)

17. Use this formula to check deadlock state.

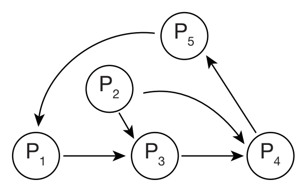
$$\sum_{i=1}^{n} S_i < (m+n)$$

S_i – Resources required for process 'i'.

m – Number of resources

n – Number of process Choice (A)

18. The wait-for-graph for given resource allocation graph is shown below:



Choice (C)

19. No dead lock exists in given graph. Choice (D)

20. Choice (A)

21. Choice (B)

22. Assume that process 2 entered critical section that results in wait of process 3, 4 and 5. But process 1 can enter. Then one more process can enter C.S. If process 1 leaves C.S., then again one more process can enter C.S. Similarly if process 1 enters and exits the C.S. again, 2 more processes can enter C.S. Choice (D)

23. Semaphores may be signalled in any order. But semaphores must be locked in same order. Choice (A)

24. Need of process 'A' is {2, 1, 3}, which is greater than available. Choice (A)

25. Process 'B' can execute in resultant state, which leads to completion of A, C and D. Choice (A)

Operating Systems Test 4

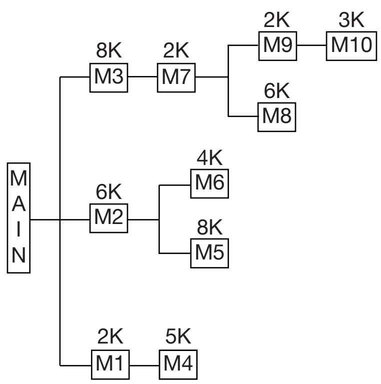
Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Suppose that, the time to service a page fault is 10 sec on average, memory access time is 1 m sec. If a page fault occurs for every 10000 references, what is the average memory access time?
(A) 1.9999 m sec (B) 1 m sec
(C) 9.999 m sec (D) 1.9999 μ sec

2. If an instruction takes 'n' micro seconds and page fault takes an additional 'm' micro seconds. If the average page fault occurs for every 'k' instructions, then effective access time is _____.
(A) $(n + m)/k$ (B) $m + n/k$
(C) $n + m/k$ (D) $n + m * k$

3. The overlay tree of the program is shown below:



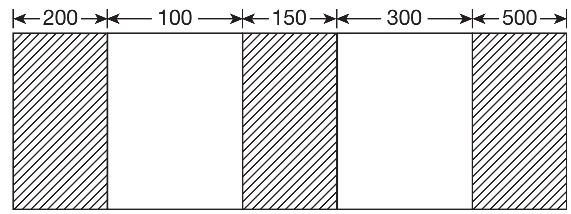
What will be the minimum partition size required to execute the program?
(A) 50K (B) 11K
(C) 8K (D) 20K

4. Dirty bit for a page table ________.
(i) helps to reduce number of page faults
(ii) helps to reduce page fault penalty
(iii) helps to avoid unnecessary writes on a paging device.
Which of the following is true?
(A) (i) (ii) (B) (i) (iii)
(C) (ii) (iii) (D) (i) (ii) and (iii)

5. A 2000 KB memory is managed using variable partitions but with no compaction. If, there exists two free partitions with sizes 400 KB and 250 KB. The smallest allocation request that could be denied is:
(A) 225K (B) 375K
(C) 425K (D) 650K

6. The address sequence generated during the execution of a program is given below:
681 351 357 421 499 099 118 129 654 454
There exists only one free frame, with the size 100 records per frame. If pure demand paging is used, what is the number of page faults?
(A) 10 (B) 9
(C) 8 (D) 7

7. Consider the following heap.



The hatched regions are not free. The sequence of requests for the blocks of size 250, 25, 75, 50 can be satisfied if we use:
(i) First fit (ii) Best fit
(iii) Worst fit
(A) (i) (ii) (B) (ii) (iii)
(C) (i) (iii) (D) (i) (ii) and (iii)

8. Consider a system with 128 MB physical memory and a 32-bit virtual address space. If the page size is 2 KB, what is the approximate page table size?
(A) 2 MB (B) 4 MB
(C) 8 MB (D) 16 MB

9. Match the following:

List–1		List–2	
1.	Virtual memory	p.	Spatial locality
2.	Shared memory	q.	Mutual exclusion
3.	Look-ahead buffer	r.	Temporal locality
4.	Look-aside buffer	s.	Address translation

	1	2	3	4
(A)	p	q	r	s
(B)	s	q	r	p
(C)	q	p	s	r
(D)	s	r	q	p

10. Let a memory has five free blocks $2k$, $4k$, $6k$, $8k$ and $20k$. These blocks are allocated using best fit strategy. The allocations requests are stored in a queue as shown below:

Job	P_1	P_2	P_3	P_4	P_5	P_6	P_7	P_8
Size	$2k$	$16k$	$4k$	$5k$	$7k$	$12k$	$8k$	$18k$
Time	4	9	3	7	6	2	8	10

The time at which the process '$P7$' will be completed is _______.
(A) 8 (B) 14
(C) 21 (D) 39

11. Consider a memory consisting of the following holes in the given order:
20K, 15K, 28K, 18K, 23K, 24K and 30K
For the request sequence 24K, 22K and 18K, the first fit allocates the Blocks _______.
(A) 24K, 23K, 18K (B) 28K, 23K, 20K
(C) 28K, 24K, 20K (D) 28K, 23K, 24K

12. Consider the following statements:
*S*1: Segmentation may suffer from external fragmentation.
*S*2: Paging may suffer from internal fragmentation.
*S*3: Segmentation may suffer from internal fragmentation.
*S*4: Paging may suffer from external fragmentation.
Which of the following are true?
(A) *S*1, *S*3 (B) *S*3, *S*4
(C) *S*1, *S*2 (D) *S*1, *S*2, *S*3, *S*4

13. Inverted Page Table contains,
(A) Page Number, Process ID, Offset.
(B) Page Number, Frame Number, Link Field
(C) Page Number, Process ID, Link field
(D) Page Number, Frame Number, Process ID

14. Consider a simple paging system with 4 GB main memory and 256 MB virtual memory. The page size is 1 KB. Based on this dat*a*, Match the following:

List-1		List-2	
1.	Bits in Logical Address	p.	22
2.	Bits in Frame Number	q.	18
3.	Entries in Page Table	r.	28
4.	Bits in Page Number	s.	2^{18}

	1	2	3	4
(A)	r	p	s	q
(B)	p	q	r	s
(C)	r	p	q	s
(D)	r	s	p	q

15. Consider the following page reference sequence:
2, 1, 5, 2, 2, 1, 3, 6, 4, 2, 5, 1, 3, 6
How many page faults will occur using LRU, FIFO and optimal respectively, if the memory contains 6 frames?
(A) 6 6 6 (B) 6 5 4
(C) 5 6 4 (D) 7 8 6

16. In a particular Unix OS, the *i*-node block of size 2K, contains 10 direct data block, addresses, one address for single indirect block. One for double indirect block, and one for Triple indirect block. Each block can contain 128 addresses. The approximate maximum size of the file in the file system is __________.
(A) 2 GB (B) 4 GB
(C) 8 GB (D) 16 GB

17. Consider a system with four files of sizes 11150 B, 4970 B, 5520 B and 10640 B. For storing these files on disk we can use either 100 B blocks or 200 B blocks but not both. For each block 4 B are used for book information. A disk block can store either book keeping information or file data, but not both.
What is the total number of blocks required for files using 100 B blocks and 200 B blocks respectively?
(A) 340 and 338 (B) 340 and 169
(C) 340 and 170 (D) 315 and 163

18. Hard disk transfers 20 MB/sec using DMA. The processor runs at 1.2 GHz takes 600 and 1800 clocks to initiate and terminate DMA transfer respectively. If the size of transfer is 10 KB, what is the percentage of processor time consumed for the transfer operation?
(A) 4% (B) 0.4%
(C) 1% (D) 10%

19. Consider a disk pack with 16 platters, each with 2 surfaces, 256 tracks per surface, 512 sectors per track and 1 KB sector size. The capacity of the disk and number bits required to address a sector uniquely in the disk are respectively:
(A) 8 GB, 32 bits (B) 4 GB, 22 bits
(C) 4 GB, 32 bits (D) 16 GB, 22 bits

20. Which of the following request set will cause the head to change its direction after servicing every request assuming that the head does not change direction if there is a tie in SSTF and all the requests arrive before the servicing starts?
(A) 1, 129, 160, 168, 171, 174, 191, 255
(B) 0, 128, 160, 168, 171, 175, 191, 255
(C) 0, 129, 159, 168, 171, 174, 191, 255
(D) 0, 128, 160, 168, 171, 175, 190, 255

21. What is the maximum cardinality of request set, so that head changes its direction for every request service, if there exists a total of 4096 tracks and head can start from any track?
(A) 10 (B) 11
(C) 12 (D) 13

22. Consider a disk with 100 cylinders. The per track seek time is 2 m sec. The requests to access the cylinders occurs in the following sequence:
5, 40, 15, 12, 24, 65, 3, 18, 10
Assuming that the head is currently at 55 cylinder, what is the time taken to satisfy all the requests using SSTF.
(A) 72 m sec (B) 144 m sec
(C) 204 m sec (D) 102 m sec

23. Consider a disk with 100 cylinders. The per track seek time given as 3 m sec. The requests to access the cylinders occurs in the following sequence:
25, 45, 65, 32, 75, 15, 50, 20
What is the total seek time using FCFS disk scheduling. Assume that the initial position of head is at track 0.
(A) 269 (B) 300
(C) 807 (D) 225

24. Consider a system with 3 memory frames and the following reference string over 8 pages: 1, 2, 3, 4, 2, 8, 1, 3, 5, 7, 6, 1, 2
What will be the final content of memory if FIFO replacement policy used.
(A) 6 1 2
(B) 1 2 6
(C) 1 6 2
(D) 2 1 6

25. For the above count what will be the number of page faults if LRU is used?
(A) 10 (B) 11
(C) 12 (D) 13

Answer Keys

1. A	**2.** C	**3.** D	**4.** C	**5.** C	**6.** D	**7.** C	**8.** B	**9.** A	**10.** B
11. B	**12.** C	**13.** C	**14.** A	**15.** A	**16.** B	**17.** B	**18.** B	**19.** B	**20.** B
21. C	**22.** B	**23.** C	**24.** A	**25.** C					

Hints and Explanations

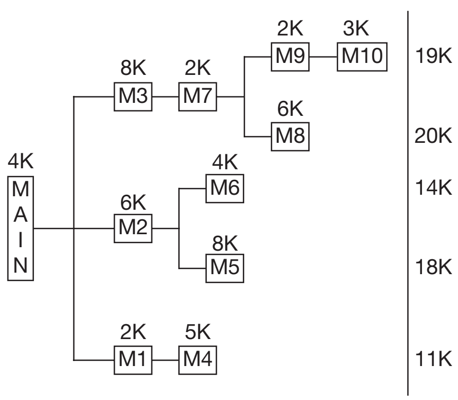
1. EAT = H*MAT + (1 – H)*($P.F.T$)
H = 0.9999 (1 page fault for every 10000)
MAT = 1 m sec
$P.F.T$ = 10 sec
EAT = 0.9999 * 1 m sec + (0.0001)* 10 sec.
= 0.9999 + 1 m sec
= 1.9999 m sec Choice (A)

2. EAT = H * MAT + (1 – H)*($P.F.T$ + MAT)

$$= \frac{k-1}{k} \times n + \frac{1}{k}(m+n)$$

$$= n + \frac{m}{k}$$ Choice (C)

3.



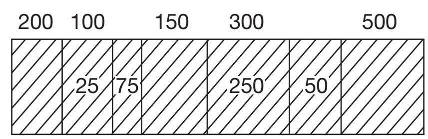
The maximum memory required when module $M8$ is under execution, which is 20K. Choice (D)

4. Choice (C)

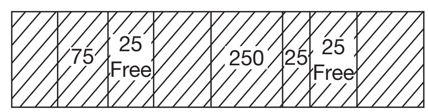
5. Choice (C)

6. 681 351 357 421 499 019 118 129 654 454
PF PF PH PF PH PF PF PH PF PF
$PF \rightarrow$ Page Fault, $PH \rightarrow$ Page Hit
Number of PFs = 7 Choice (D)

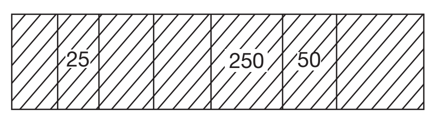
7. First Fit:



Best Fit:



50 cannot be allocated.
Worst Fit:



Choice (C)

8. Number of page $= \dfrac{\text{(Virtual memory size)}}{\text{(Page size)}}$

Number of frames $= \dfrac{\text{Main Memory size}}{\text{Page size}} = \dfrac{2^{27}}{2^{11}} = 2^{16}$

Page Table size = Number of pages * Number of bits to address frame
= 2^{21} * 16 bits
= 2^{21} * 2 B = 4 MB Choice (B)

9. Choice (A)

10.

2K	4K	6K	8K	20K
P1	P3	P4	P5	P2

On completion of $P5$, Block 4 will be allocated to $P7$.
Hence completion time of $P7$ is = 6 + 8 = 14
Choice (B)

11. Choice (B)

12. Choice (C)

13. Choice (C)

14. Virtual memory = 256 MB = 2^{28} B

Bits in logical address = 28

Number of frames $= \dfrac{4\text{ GB}}{1\text{ kB}} = \dfrac{2^{32}}{2^{10}} = 2^{22}$

Number of bits in frame Number = 22

Number of pages $= \dfrac{256\text{ MB}}{1\text{ kB}} = \dfrac{2^{28}}{2^{10}} = 2^{18}$

Number of entries in page table = 2^{18}

Number of bits in page number = 18 Choice (A)

15. Number of pages referred is 6, Number of frames also 6. Hence for any algorithm, number of page faults are 6. Choice (A)

16. Maximum file size

$$[\underset{\text{Inode}}{1} + \underset{\text{Direct}}{10} + \underset{\text{Single indirect}}{(1+128)} + \overbrace{(1+128+128\times128)}^{\text{Double indirect}}$$
$$+ \underbrace{(1+128+128\times128+128\times128\times128)]}_{\text{Triple indirect}}$$

$2k$ (Block size)

$\cong$ 4 GB Choice (B)

17.

File Size	100B Data Blocks	Book Keeping Blocks
11150	112	5
4970	50	2
5520	56	3
10640	107	5
Total	325	15

Total = 340

File Size	200B Data Blocks	Book Keeping Blocks
11150	56	2
4970	25	1
5520	28	1
10640	54	2
Total	163	6

Total = 169 Choice (B)

18. **Transfer Time:**

20 MB – 1 sec

10 KB – x

x*20 MB = 1 sec * 10 KB

x = ½ m sec = 500 µ sec

CPU Time:

1.2 GHz ⇒ 1.2 * 10^9 clocks/sec

= 1200 * 10^6 clocks/sec

CPU Time consumed = 600 + 1800

= 2400 clocks

1200 * 10^6 clocks – 1 sec

2400 clocks – y

y * 1200 × 10^6 = 1 sec * 2400

y = 2 µs

Percentage of CPU involvement

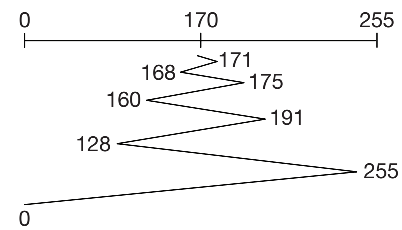
$= \dfrac{2\,\mu\text{s}}{500\,\mu\text{s}} \times 100 = 0.4\%$ Choice (B)

19. Disk Capacity = 16 * 2 * 256 * 512 * 1 KB = 4 GB

Number of sectors = 16 × 2 × 256 × 512 = 2^{22}

Choice (B)

20. Assume the head at track 170 (Based on choices). Then

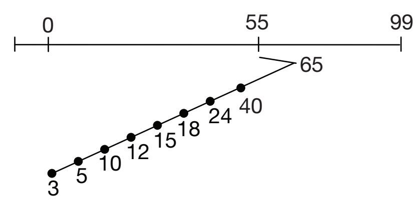


Choice (B)

21. 4096 = 2^{12} tracks

Hence cardinality = 12 Choice (C)

22.



Total tracks moved = 72

Total seek time = 72 × 2 = 144 m sec Choice (B)

23.

Chapter 1

Lexical Analysis and Parsing

LEARNING OBJECTIVES

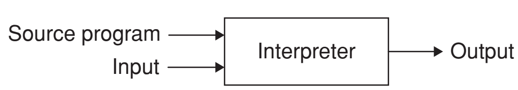
- *Language processing system*
- *Lexical analysis*
- *Syntax analysis*
- *Context free grammars and ambiguity*
- *Types of parsing*
- *Top down parsing*
- *Bottom up parsing*
- *Conflicts*
- *Operator precedence grammar*
- *LR parser*
- *Canonical LR parser(CLR)*

Language Processing System

Language Processors

Interpreter

It is a computer program that executes instructions written in a programming language. It either executes the source code directly or translates source code into some efficient intermediate representation and immediately executes this.



Example: Early versions of Lisp programming language, BASIC.

Translator

A software system that converts the source code from one form of the language to another form of language is called as translator. There are 2 types of translators namely (1) Compiler (2) Assembler.

Compiler converts source code of high level language into low level language.

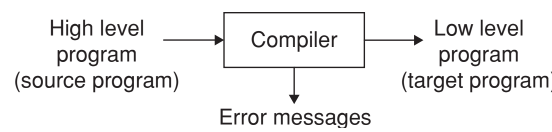
Assembler converts assembly language code into binary code.

Compilers

A compiler is a software that translates code written in high-level language (i.e., source language) into target language.

Example: source languages like C, Java,… etc. Compilers are user friendly.

The target language is like machine language, which is efficient for hardware.



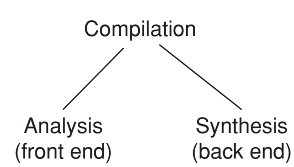
Passes

The number of iterations to scan the source code, till to get the executable code is called as a pass.

Compiler is two pass. Single pass requires more memory and multipass require less memory.

Analysis–synthesis model of compilation

There are two parts of compilation:

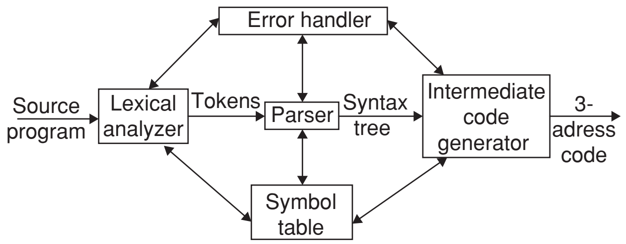


Analysis It breaks up the source program into pieces and creates an intermediate representation of the source program. This is more language specific.

Synthesis It constructs the desired target program from the intermediate representation. The target program will be more machine specific, dealing with registers and memory locations.

Front end vs back end of a compiler

The front end includes all analysis phases and intermediate code generator with part of code optimization.



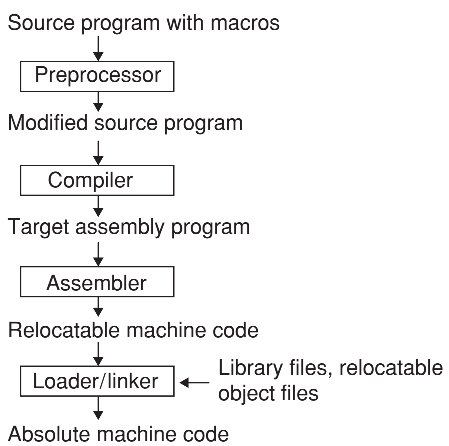
The back end includes code optimization and code generation phases. The back end synthesizes the target program from intermediate code.

Context of a compiler

In addition to a compiler, several other programs may be required to create an executable target program, like preprocessor to expand macros.

The target program created by a compiler may require further processing before it can be run.

The language processing system will be like this:



Phases

Compilation process is partitioned into some subproceses called phases.

In order to translate a high level code to a machine code, we need to go phase by phase, with each phase doing a particular task and parsing out its output for the next phase.

Lexical analysis or scanning

It is the first phase of a compiler. The lexical analyzer reads the stream of characters making up the source program and groups the characters into meaningful sequences called lexemes.

Example: Consider the statement: if $(a < b)$

In this sentence the tokens are if, $(a, <, b,)$.

Number of tokens = 6

Identifiers: a, b

Keywords: if

Operators: <, (,)

Syntax analyzer or Parser

- Tokens are grouped hierarchically into nested collections with collective meaning.
- A context free grammar (CFG) specifies the rules or productions for identifying constructs that are valid in a programming language. The output is a parse/syntax/derivation tree.

Example: Parse tree for –(id + id) using the following grammar:

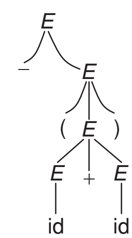
$E \to E + E$

$E \to E * E$

$E \to -E \qquad (G_1)$

$E \to (E)$

$E \to id$



Semantic analysis

- It checks the source program for semantic errors.
- Type checking is done in this phase, where the compiler checks that each operator has matching operands for semantic consistency with the language definition.
- Gathers the type information for the next phases.

Example 1: The bicycle rides the boy.

This statement has no meaning, but it is syntactically correct.

Example 2:

```
int a;
bool b;
char c;
c = a + b;
```

We cannot add integer with a Boolean variable and assign it to a character variable.

Intermediate code generation

The intermediate representation should have two important properties:

(i) It should be easy to produce.

(ii) Easy to translate into the target program

'Three address code' is one of the common forms of Intermediate code.

Three address code consists of a sequence of instructions, each of which has at most three operands.

Example:

$\mathtt{id_1 = id_2 + id_3 \times 10;}$

$\mathtt{t_1 := inttoreal(10)}$

$t_2 := id_3 \times t_1$

$t_3 := id_2 + t_2$

$id_1 = t_3$

Code optimization

The output of this phase will result in faster running machine code.

Example: For the above intermediate code the optimized code will be

$t_1 := id_3 \times 10.0$

$id_1 : = id_2 + t1$

In this we eliminated t_2 and t_3 registers.

Code generation

- In this phase, the target code is generated.
- Generally the target code can be either a relocatable machine code or an assembly code.
- Intermediate instructions are each translated into a sequence of machine instructions.
- Assignment of registers will also be done.

Example:

MOVF	id_3, R_2
MULF	≠ 60.0, R_2
MOVF	id_2, R_1
ADDF	R_2, R_1
MOVF	R_1, id_1

Symbol table management

A symbol table is a data structure containing a record for each variable name, with fields for the attributes of the name.

What is the use of a symbol table?

1. To record the identifiers used in the source program.
2. Its type and scope
3. If it is a procedure name then the number of arguments, types of arguments, the method of parsing (by reference) and the type returned.

Error detection and reporting

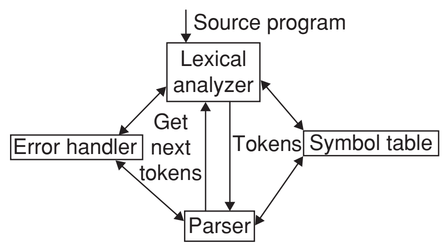
(i) Lexical phase can detect errors where the characters remaining in the input 'do not form any token'.
(ii) Errors of the type, 'violation of syntax' of the language are detected by syntax analysis.
(iii) Semantic phase tries to detect constructs that have the right syntactic structure but no meaning.

Example: adding two array names etc.

Lexical Analysis

Lexical Analysis is the first phase in compiler design. The main task of the lexical analyzer is to read the input characters of the source program, group them into lexemes, and produce as output a sequence of tokens for each lexeme in the source program. The stream of tokens is sent to the parser for syntax analysis.

There will be interaction with the symbol table as well.



Lexeme: Sequence of characters in the source program that matches the pattern for a token. It is the smallest logical unit of a program.

Example: 10, x, y, <, >, =

Tokens: These are the classes of similar lexemes.

Example: Operators: <, >, =
Identifiers: x, y
Constants: 10
Keywords: if, else, int

Operations performed by lexical analyzer

1. Identification of lexemes and spelling check
2. Stripping out comments and white space (blank, new line, tab etc).
3. Correlating error messages generated by the compiler with the source program.
4. If the source program uses a macro-preprocessor, the expansion of macros may also be performed by lexical analyzer.

Example 1: Take the following example from Fortran
DO 5 I = 1.25
Number of tokens = 5
The 1st lexeme is the keyword DO
Tokens are DO, 5, I, =, 1.25.

Example 2: An example from C program
for (int i = 1; i < = 10; i + +)
Here tokens are for, (, int, i, =, 1,;, i, < =, 10,;, i, ++,)
Number of tokens = 13

LEX compiler

Lexical analyzer divides the source code into tokens. To implement lexical analyzer we have two techniques namely hand code and the other one is LEX tool.

LEX is an automated tool which specifies lexical analyzer, from the rules given by the regular expression.

These rules are also called as pattern recognizing rules.

Syntax Analysis

This is the 2nd phase of the compiler, checks the syntax and constructs the syntax/parse tree.

Input of parser is token and output is a parse/ syntax tree.

Constructing parse tree

Construction of derivation tree for a given input string by using the production of grammar is called parse tree.

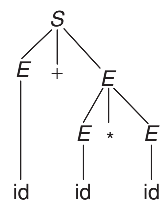
Consider the grammar

$S \to E + E/E * E$

$E \to id$

The parse tree for the string

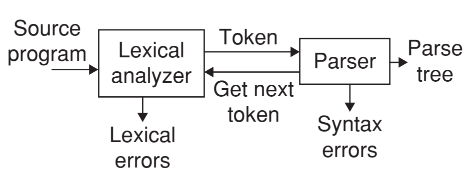
$\omega = id + id * id$ is



$\omega = id + id * id$

Role of the parser

1. Construct a parse tree.
2. Error reporting and correcting (or) recovery. A parser can be modeled by using CFG (Context Free Grammar) recognized by using pushdown automata/table driven parser.
3. CFG will only check the correctness of sentence with respect to syntax not the meaning.



How to construct a parse tree?

Parse tree's can be constructed in two ways.

(i) Top-down parser: It builds parse trees from the top (root) to the bottom (leaves).

(ii) Bottom-up parser: It starts from the leaves and works up to the root.

In both cases, the input to the parser is scanned from left to right, one symbol at a time.

Parser generator

Parser generator is a tool which creates a parser.

Example: compiler – compiler, YACC

The input of these parser generator is grammar we use and the output will be the parser code.

The parser generator is used for construction of the compilers front end.

Scope of declarations

Declaration scope refers to the certain program text portion, in which rules are defined by the language.

Within the defined scope, entity can access legally to declared entities.

The scope of declaration contains immediate scope always. Immediate scope is a region of declarative portion with enclosure of declaration immediately.

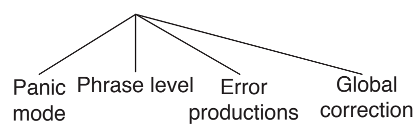
Scope starts at the beginning of declaration and scope continues till the end of declaration. Whereas in the over loadable declaration, the immediate scope will begin, when the callable entity profile was determined.

The visible part refers text portion of declaration, which is visible from outside.

Syntax Error Handling

1. Reports the presence of errors clearly and accurately.
2. Recovers from each error quickly.
3. It should not slow down the processing of correct programs.

Error Recovery Strategies



Panic mode On discovering an error, the parser discards input symbols one at a time until one of the synchronizing tokens is found.

Phrase level A parser may perform local correction on the remaining input. It may replace the prefix of the remaining input.

Error productions Parser can generate appropriate error messages to indicate the erroneous construct that has been recognized in the input.

Global corrections There are algorithms for choosing a minimal sequence of changes to obtain a globally least cost correction.

Context Free Grammars and Ambiguity

A grammar is a set of rules or productions which generates a collection of finite/infinite strings.

It is a 4-tuple defined as $G = (V, T, P, S)$

Where

V = set of variables

T = set of terminals

P = set of production rules

S = start symbol

Example: $S \to (S)/e$

$S \to (S)$ (1)

$S \to e$ (2)

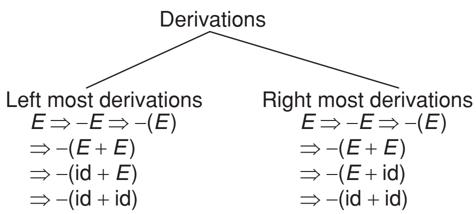
Here S is start symbol and the only variable.
(,), e is terminals.
(1) and (2) are production rules.

Sentential forms

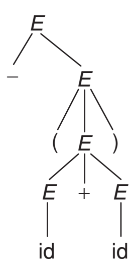
$s \overset{*}{\Rightarrow} \alpha$, Where α may contain non-terminals, then we say that α is a sentential form of G.

Sentence: A sentence is a sentential form with no non-terminals.

Example: $-(id + id)$ is a sentence of the grammar (G_1).



Right most derivations are also known as canonical derivations.



Ambiguity

A grammar that produces more than one parse tree for some sentence is said to be ambiguous.

Or

A grammar that produces more than one left most or more than one right most derivations is ambiguous.

For example consider the following grammar:

String → String + String/String – String /0/1/2/…/9

9 – 5 + 2 has two parse trees as shown below

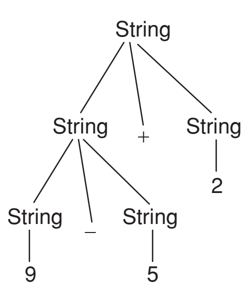


Figure 1 Leftmost derivation

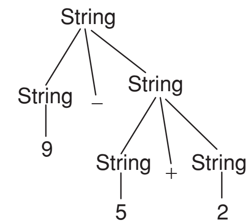

Figure 2 Rightmost derivation

- Ambiguity is problematic because the meaning of the program can be incorrect.
- Ambiguity can be handled in several ways
  1. Enforce associativity and precedence
  2. Rewrite the grammar by eliminating left recursion and left factoring.

Removal of ambiguity

The grammar is said to be ambiguous if there exists more than one derivation tree for the given input string.

The ambiguity of grammar is undecidable; ambiguity of a grammar can be eliminated by rewriting the grammar.

Example:

$E \to E + E/id\}$ → ambiguous grammar

$\left.\begin{array}{l} E \to E + T/T \\ T \to id \end{array}\right\}$ rewritten grammar (unambiguous grammar)

Left recursion

Left recursion can take the parser into infinite loop so we need to remove left recursion.

Elimination of left recursion

$A \to A\alpha/\beta$ is a left recursive.

It can be replaced by a non-recursive grammar:

$$A \to \beta A'$$
$$A' \to \alpha A'/\varepsilon$$

In general

$$A \to A\alpha_1/A\alpha_2/\ldots/A\alpha_m/\beta_1/\beta_2/\ldots/\beta_n$$

We can replace A productions by

$$A \to \beta_1 A'/\beta_2 A'/\text{–}\beta_n A'$$
$$A' \to \alpha_1 A'/\alpha_2 A'/\text{–}\alpha_m A'$$

Example 3: Eliminate left recursion from

$E \to E + T/T$

$T \to T * F/F$

$F \to (E)/\text{id}$

Solution $E \to E + T/T$ it is in the form

$A \to A\alpha/\beta$

So, we can write it as $E \to TE'$

$E' \to +TE'/\varepsilon$

Similarly other productions are written as

$$T \to FT'$$
$$T^1 \to \times FT'/\in$$
$$F \to (E)/\text{id}$$

Example 4 Eliminate left recursion from the grammar

$$S \to (L)/a$$
$$L \to L, S/b$$

Solution: $S \to (L)/a$

$L \to bL'$

$L' \to SL'/\in$

Left factoring

A grammar with common prefixes is called non-deterministic grammar. To make it deterministic we need to remove common prefixes. This process is called as Left Factoring.

The grammar: $A \to \alpha\beta_1/\alpha\beta_2$ can be transformed into

$A \to \alpha A'$

$A' \to \beta_1/\beta_2$

Example 5: What is the resultant grammar after left factoring the following grammar?

$S \to iEtS/iEtSeS/a$

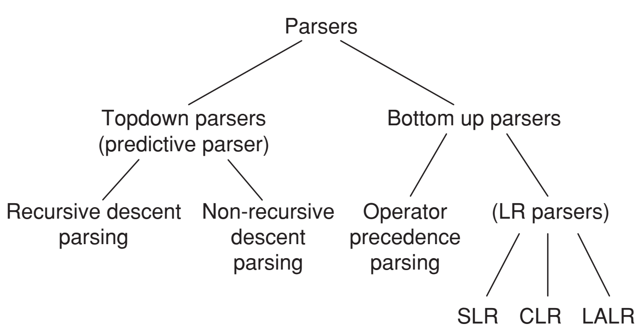
$E \to b$

Solution: $S \to iEtSS'/a$

$S' \to eS/\in$

$E \to b$

Types of Parsing



Topdown Parsing

A parse tree is constructed for the input starting from the root and creating the nodes of the parse tree in preorder. It simulates the left most derivation.

Backtracking Parsing

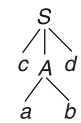
If we make a sequence of erroneous expansions and subsequently discover a mismatch we undo the effects and roll back the input pointer.

This method is also known as brute force parsing.

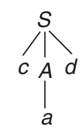
Example: $S \to cAd$

$A \to ab/a$

Let the string w = cad is to generate:



The string generated from the above parse tree is cabd.
but, w = cad, the third symbol is not matched.
So, report error and go back to A.
Now consider the other alternative for production A.



String generated 'cad' and $w = cad$. Now, it is successful.

In this we have used back tracking. It is costly and time consuming approach. Thus an outdated one.

Predictive Parsers

By eliminating left recursion and by left factoring the grammar, we can have parse tree without backtracking. To construct a predictive parser, we must know,

1. Current input symbol
2. Non-terminal which is to be expanded

A procedure is associated with each non-terminal of the grammar.

Recursive descent parsing

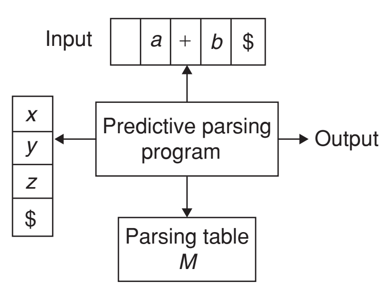
In recursive descent parsing, we execute a set of recursive procedures to process the input.

The sequence of procedures called implicitly, defines a parse tree for the input.

Non-recursive predictive parsing

(table driven parsing)

- It maintains a stack explicitly, rather than implicitly via recursive calls.
- A table driven predictive parser has
  - $\to$ An input buffer
  - $\to$ A stack
  - $\to$ A parsing table
  - $\to$ Output stream



Constructing a parsing table

To construct a parsing table, we have to learn about two functions:

1. FIRST ( )
2. FOLLOW ( )

FIRST(X) To compute FIRST(X) for all grammar symbols X, apply the following rules until no more terminals or ε can be added to any FIRST set.

1. If X is a terminal, then FIRST(X) is $\{X\}$.
2. If $X \rightarrow \varepsilon$ is a production, then add ε to FIRST(X).
3. If X is non-terminal and $X \rightarrow Y_1 Y_2 - Y_k$ is a production, then place 'a' in FIRST(X) if for some i, a is an FIRST (Y_i) and $\in$ is in all of FIRST(Y_1), …, FIRST(Y_{i-1}); that is, $Y_1, \ldots, Y_{i-1} \overset{*}{\Rightarrow} \in$. If $\in$ is in FIRST (Y_j) for all $j = 1, 2, \ldots, k$, then add $\in$ to FIRST(X). For example, everything in FIRST (Y_1) is surely in FIRST(X). If Y_1 does not derive $\in$, then add nothing more to FIRST(X), but if $Y_1 \overset{*}{\Rightarrow} \in$, then add FIRST ($Y_2$) and so on.

FOLLOW (A): To compute FOLLOW (A) for all non-terminals A, apply the following rules until nothing can be added to any FOLLOW set.

1. Place \$ in FOLLOW(S), where S is the start symbol and \$ is input right end marker.
2. If there is a production $A \rightarrow \alpha B \beta$, then everything in FIRST (β) except ε is placed in FOLLOW (B).
3. If there is a production $A \rightarrow \alpha B$ or a production $A \rightarrow \alpha B \beta$, where FIRST ($\beta$) contains ε, then everything in FOLLOW (A) is in FOLLOW (B).

Example: Consider the grammar

$E \rightarrow TE'$
$E' \rightarrow +TE'/\varepsilon$
$T \rightarrow FT'$
$T' \rightarrow *FT'/\varepsilon$
$F \rightarrow (E)/id$. Then
FIRST (E) = FIRST (T) = FIRST (F) = $\{(, id\}$
FIRST (E') = $\{^+, \varepsilon\}$
FIRST (T') = $\{^*, \varepsilon\}$
FOLLOW (E) = FOLLOW (E') = {), \$}
FOLLOW (T) = FOLLOW (T') = {+,), \$}
FOLLOW (F) = {*, +,), \$}

Steps for the construction of predictive parsing table

1. For each production $A \rightarrow \alpha$ of the grammar, do steps 2 and 3.
2. For each terminal a in FIRST (α), add $A \rightarrow \alpha$ to $M[A, a]$
3. If ε is in FIRST (α), add $A \rightarrow \alpha$ to $M[A, b]$ for each terminal b in FOLLOW (A). If ε is in FIRST (α) and \$ is in FOLLOW (A), add $A \rightarrow \alpha$ to $M[A, \$]$
4. Make each undefined entry of M be error.

By applying these rules to the above grammar, we will get the following parsing table.

	Input Symbol					
Non-terminal	**id**	**+**	*****	**(**	**)**	**\$**
E	$E \rightarrow TE'$			$E \rightarrow TE'$		
E'		$E' \rightarrow +TE'$			$E' \rightarrow \varepsilon$	$E' \rightarrow \varepsilon$
T	$T \rightarrow FT'$			$T \rightarrow FT'$		
T'		$T' \rightarrow \varepsilon$	$T' \rightarrow *FT'$		$T' \rightarrow \varepsilon$	$T' \rightarrow \varepsilon$
F	$F \rightarrow id$			$F \rightarrow (E)$		

The parser is controlled by a program. The program consider x, the symbol on top of the stack and 'a' the current input symbol.

1. If $x = a = \$$, the parser halts and announces successful completion of parsing.
2. If $x = a \neq \$$, the parser pops x off the stack and advances the input pointer to the next input symbol.
3. If x is a non-terminal, the program consults entry $M[x, a]$ of the parsing table M. This entry will be either an x-production of the grammar or an error entry. If $M[x, a] = \{x \rightarrow UVW\}$, the parser replaces x on top of the stack by WVU with U on the top.

If $M[x, a]$ = error, the parser calls an error recovery routine.
For example, consider the moves made by predictive parser on input id + id $*$ id, which are shown below:

Matched	Stack	Input	Action
	E\$	id+id*id\$	
	TE′\$	id+id*id\$	Output E → TE′
	FT′E′\$	id+id*id\$	Output T → FT′
	idT′E′\$	id+id*id\$	Output F → id
id	T′E′\$	+id*id\$	Match id
id	E′\$	+id*id\$	Output T′→ ε
id	+TE′\$	+id*id\$	Output E′→ +TE′
id+	TE′\$	id*id\$	Match+
id+	FT′E′\$	id*id\$	Output T → FT′
id+	idT′E′\$	id*id\$	Output F → id
id+id	T′E′\$	*id\$	Match id
id+id	*FT′E′\$	*id\$	Output T′ → *FT′
id+id*	FT′E′\$	id\$	Match*
id+id*	idT′E′\$	id\$	OutputF → id
id+id*id	T′E′\$	\$	Match id
id+id*id	E′\$	\$	Output T′ → ε
id+id*id	\$	\$	Output E′ → ε

Bottom up Parsing

- This parsing constructs the parse tree for an input string beginning at the leaves and working up towards the root.
- General style of bottom-up parsing is shift-reduce parsing.

Shift–Reduce Parsing

Reduce a string to the start symbol of the grammar. It simulates the reverse of right most derivation.

In every step a particular substring is matched (in left right fashion) to the right side of some production and then it is substituted by the non-terminal in the left hand side of the production.

For example consider the grammar

$S \rightarrow aABe$

$A \rightarrow Abc/b$

$B \rightarrow d$

In bottomup parsing the string 'abbcde' is verified as

$$\left.\begin{array}{l} abbcde \\ aAbcde \\ aAde \\ aABe \\ S \end{array}\right\} \rightarrow \text{ reverse order}$$

Stack implementation of shift–reduce parser

The shift reduce parser consists of input buffer, Stack and parse table.

Input buffer consists of strings, with each cell containing only one input symbol.

Stack contains the grammar symbols, the grammar symbols are inserted using shift operation and they are reduced using reduce operation after obtaining handle from the collection of buffer symbols.

Parse table consists of 2 parts goto and action, which are constructed using terminal, non-terminals and compiler items.

Let us illustrate the above stack implementation.

$\rightarrow$ Let the grammar be

$S \rightarrow AA$

$A \rightarrow aA$

$A \rightarrow b$

Let the input string 'ω' be abab\$

ω = abab\$

Stack	Input String	Action
\$	*abab*\$	Shift
\$*a*	*bab*\$	Shift
\$*ab*	*ab*\$	Reduce ($A \rightarrow b$)
\$*aA*	*ab*\$	Reduce ($A \rightarrow aA$)
\$*A*	*ab*\$	Shift
\$*Aa*	*b*\$	Shift
\$*Aab*	\$	Reduce ($A \rightarrow b$)
\$*AaA*	\$	Reduce ($A \rightarrow aA$)
\$*AA*	\$	Reduce ($S \rightarrow AA$)
\$*S*	\$	Accept

Rightmost derivation

$S \Rightarrow aABe \Rightarrow aAde \Rightarrow aAbcde \Rightarrow abbcde$

For bottom up parsing, we are using right most derivation in reverse.

Handle of a string Substring that matches the RHS of some production and whose reduction to the non-terminal on the LHS is a step along the reverse of some rightmost derivation.

$$S \overset{rm}{\underset{*}{\Rightarrow}} \alpha Ar \Rightarrow \alpha\beta r$$

Right sentential forms of a unambiguous grammar have one unique handle.

Example: For grammar, $S \rightarrow aABe$

$A \rightarrow Abc/b$

$B \rightarrow d$

$S \Rightarrow \underline{aABe} \Rightarrow aA\underline{d}e \Rightarrow a\underline{Abc}de \Rightarrow a\underline{b}bcde$

Note: Handles are underlined.

Handle pruning The process of discovering a handle and reducing it to the appropriate left hand side is called handle pruning. Handle pruning forms the basis for a bottomup parsing.

To construct the rightmost derivation:

$$S = r_0 \Rightarrow r_1 \Rightarrow r_2 \_\_\_\_ \Rightarrow r_n = w$$

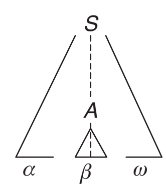
Apply the following simple algorithm:

For $i \leftarrow n$ to 1

Find the handle $A_i \rightarrow B_i$ in r_i

Replace B_i with A_i to generate r_{i-1}

Consider the cut of a parse tree of a certain right sentential form:



Here $A \rightarrow \beta$ is a handle for $\alpha\beta\omega$.

Shift reduce parsing with a stack There are 2 problems with this technique:

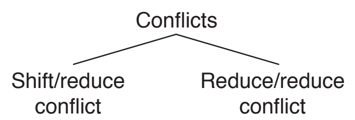
(i) To locate the handle
(ii) Decide which production to use

General construction using a stack

1. 'Shift' input symbols onto the stack until a handle is found on top of it.
2. 'Reduce' the handle to the corresponding non-terminal.
3. 'Accept' when the input is consumed and only the start symbol is on the stack.
4. Errors – call an error reporting/recovery routine.

Viable prefixes The set of prefixes of a right sentential form that can appear on the stack of a shift reduce parser are called viable prefixes.

Conflicts



Shift/reduce conflict

Example: stmt → if expr then stmt | if expr then stmt else stmt | any other statement

If exp then stmt is on the stack, in this case we can't tell whether it is a handle. i.e., 'shift/reduce' conflict.

Reduce/reduce conflict

Example: $S \to aA/bB$
$A \to c$
$B \to c$
W = ac it gives reduce/reduce conflict.

Operator Precedence Grammar

In operator grammar, no production rule can have:

- ε at the right side.
- two adjacent non-terminals at the right side.

Example 1: $E \to E + E\,/E - E/$ id is operator grammar.

Example 2: $\left.\begin{array}{l} E \to AB \\ A \to a \\ B \to b \end{array}\right\}$ not operator grammar

Example 3: $\underbrace{E \to E0E/\text{id}}_{\text{not operator grammar}}$

Precedence relation If
$a < b$ then b has higher precedence than a
$a = b$ then b has same precedence as a
$a > b$ then b has lower precedence than a

Common ways for determining the precedence relation between pair of terminals:

1. Traditional notations of associativity and precedence.

Example: × has higher precedence than + × .> + (or) + <. ×

2. First construct an unambiguous grammar for the language which reflects correct associativity and precedence in its parse tree.

Operator precedence relations from associativity and precedence

Let us use $ to mark end of each string. Define $ <. b and b ⋗ $ for all terminals b. Consider the grammar is:

$$E \to E + E/E \times E/\text{id}$$

Let the operator precedence table for this grammar is:

	id	+	×	$
id		⋗	⋗	⋗
+	⋖	⋗	⋖	⋗
×	⋖	⋗	⋗	⋗
$	⋖	⋖	⋖	accept

1. Scan the string from left until ⋗ is encountered
2. Then scan backwards (to left) over any = until ⋖ is encountered.
3. The handle contains everything to the left of the first ⋗ and to the right of the ⋖ is encountered.

After inserting precedence relation is

$id + id * id $ is

$ ⋖ id ⋗ + ⋖ id ⋗ * ⋖ id ⋗ $

Precedence functions Instead of storing the entire table of precedence relations table, we can encode it by precedence functions f and g, which map terminal symbols to integers:

1. $f(a) ⋖ f(b)$ whenever $a ⋖ b$
2. $f(a) ⋗ f(b)$ whenever $a \doteq b$
3. $f(a) > f(b)$ whenever $a ⋗ b$

Finding precedence functions for a table

1. Create symbols $f(a)$ and $g(a)$ for each 'a' that is a terminal or $.
2. Partition the created symbols into as many groups as possible in such away that $a = b$ then f (a) and g (b) are in the same group
3. Create a directed graph
   If $a < b$ then place an edge from $g(b)$ to $f(a)$
   If $a > b$ then place an edge from $f(a)$ to $g(b)$
4. If the graph constructed has a cycle then no precedence function exists.
   If there are no cycles, let $f(a)$ be the length of the longest path being at the group of $f(a)$.
   Let $g(a)$ be the length of the longest path from the group of $g(a)$.

Disadvantages of operator precedence parsing

- It can not handle unary minus.
- Difficult to decide which language is recognized by grammar.

Advantages

1. Simple
2. Powerful enough for expressions in programming language.

Error cases

1. No relation holds between the terminal on the top of stack and the next input symbol.
2. A handle is found, but there is no production with this handle as the right side.

Error recovery

1. Each empty entry is filled with a pointer to an error routine.
2. Based on the handle tries to recover from the situation.

To recover, we must modify (insert/change)

1. Stack or
2. Input or
3. Both

We must be careful that we don't get into an infinite loop.

LR Parsers

- In LR (K), L stands for Left to Right Scanning, R stands for Right most derivation, K stands for number of look ahead symbols.
- LR parsers are table-driven, much like the non-recursive LL parsers. A grammar which is used in construction of LR parser is LR grammar. For a grammar to be LR it is sufficient that a left-to-right shift-reduce parser be able to recognize handles of right-sentential forms when they appear on the top of the stack.
- The Time complexity for such parsers is $O(n^3)$
- LR parsers are faster than LL (1) parser.
- LR parsing is attractive because
  - The most general non-backtracking shift reduce parser.
  - The class of grammars that can be passed using LR methods is a proper superset of predictive parsers. LL (1) grammars $\subset$ LR (1) grammars.
  - LR parser can detect a syntactic error in the left to right scan of the input.
- LR parsers can be implemented in 3 ways:

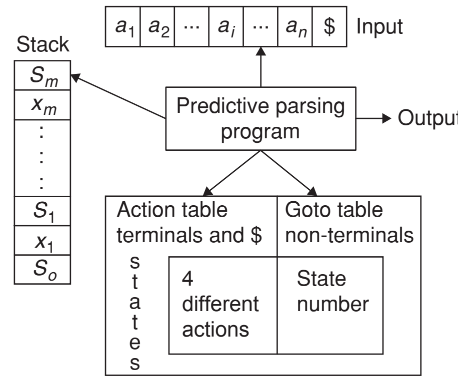
1. Simple LR (SLR): The easiest to implement but the least powerful of the three.
2. Canonical LR (CLR): most powerful and most expensive.
3. Look ahead LR (LALR): Intermediate between the remaining two. It works on most programming language grammars.

Disadvantages of LR parser

1. Detecting a handle is an overhead, parse generator is used.
2. The main problem is finding the handle on the stack and it was replaced with the non-terminal with the left hand side of the production.

The LR parsing algorithm

- It consists of an input, an output, a stack, a driver program and a parsing table that has two parts (action and goto).
- The driver/parser program is same for all these LR parsers, only the parsing table changes from parser to another.



Stack: To store the string of the form,

$S_o x_1 S_1 \ldots x_m S_m$ where

S_m: state

x_m: grammar symbol

Each state symbol summarizes the information contained in the stack below it.

Parsing table: Parsing table consists of two parts:

1. Action part
2. Goto part

ACTION Part:

Let, $S_m \rightarrow$ top of the stack
$a_i \rightarrow$ current symbol

Then action $[S_m, a_i]$ which can have one of four values:

1. Shift S, where S is a state
2. Reduce by a grammar production $A \rightarrow \beta$
3. Accept
4. Error

GOTO Part:

If goto $(S, A) = X$ where $S \rightarrow$ state, $A \rightarrow$ non-terminal, then GOTO maps state S and non-terminal A to state X.

Configuration

$$(S_o\, x_1 S_1\, x_2 S_2 - x_m S_m,\ a_i a_{i+1} - a_n \$)$$

The next move of the parser is based on action $[S_m, a_i]$

The configurations are as follows.

1. If action $[S_m, a_i]$ = shift S
$$(S_o\, x_1 S_1\, x_2 S_2 \text{---}\ x_m S_m,\ a_i a_{i+1} \text{---}\ a_n \$)$$
2. If action $[S_m, a_i]$ = reduce $A \rightarrow \beta$ then
$$(S_o\, x_1 S_1\, x_2 S_2 \text{---}\ x_{m-r} S_{m-r},\ AS,\ a_i a_{i+1} \text{---}\ a_n \$)$$
   Where S = goto $[S_{m-r}, A]$
3. If action $[S_m, a_i]$ = accept, parsing is complete.
4. If action $[S_m, a_i]$ = error, it calls an error recovery routine.

Example: Parsing table for the following grammar is shown below:

1. $E \rightarrow E + T$
2. $E \rightarrow T$

3. $T \rightarrow T * F$ 4. $T \rightarrow F$
5. $F \rightarrow (E)$ 6. $F \rightarrow \text{id}$

	Action						Goto		
State	**id**	**+**	**×**	**(**	**)**	**$**	***E***	***T***	***F***
0	S_5			S_4			1	2	3
1		S_6				*acc*			
2		r_2	S_7		r_2	r_2			
3		r_4	r_4		r_4	r_4			
4	S_5			S_4			8	2	3
5		r_6	r_6		r_6	r_6			
6	S_5			S_4				9	3
7	S_5			S_4					10
8		S_6			S_1				
9		r_1	S_7		r_1	r_1			
10		r_3	r_3		r_3	r_3			
11		r_5	r_5		r_5	r_5			

Moves of LR parser on input string id*id+id is shown below:

Stack	Input	Action
0	id * id + id$	Shift 5
0id 5	* id + id$	reduce 6 means reduce with 6th production $F \rightarrow$ id and goto [0, F] = 3
0F 3	* id + id$	reduce 4 i.e $T \rightarrow F$ goto [0, T] = 2
0T 2	* id + id$	Shift 7
0T2 * 7	id + id$	Shift 5
0T2 * 7 id 5	+ id$	reduce 6 i.e $F \rightarrow$ id goto [7, F] = 10
0T2 * 7 F 10	+ id$	reduce 3 i.e $T \rightarrow T * F$
0T 2	+ id$	goto [0, T] = 2
0E 1	+ id$	reduce 2 i.e $E \rightarrow T$ & goto [0, E] = 1
0E1 + 6	id$	Shift 6
0E1 + 6 id 5	$	Shift 5
0E1 + 6F 3	$	reduce 6 & goto [6, F] = 3
0E1 + 6T 9	$	reduce 4 & goto [6, T] = 9
0E1	$	reduce 1 & goto [0, E] = 1
0E1	$	accept

Constructing SLR parsing table

LR (0) item: LR (0) item of a grammar G is a production of G with a dot at some position of the right side of production.

Example: $A \rightarrow BCD$
Possible LR (0) items are

$A \rightarrow .BCD$
$A \rightarrow B.CD$
$A \rightarrow BC.D$
$A \rightarrow BCD.$

$A \rightarrow B.CD$ means we have seen an input string derivable from B and hope to see a string derivable from CD.

The LR (0) items are constructed as a DFA from grammar to recognize viable prefixes.

The items can be viewed as the states of NFA.

The LR (0) item (or) canonical LR (0) collection, provides the basis for constructing SLR parser.

To construct LR (0) items, define
(a) An augmented grammar
(b) closure and goto

Augmented grammar (G′) If G is a grammar with start symbol S, G' the augmented grammar for G, with new start symbol S' and production $S' \rightarrow S$.

Purpose of G' is to indicate when to stop parsing and announce acceptance of the input.

Closure operation Closure (I) includes

1. Intially, every item in I is added to closure (I)
2. If $A \rightarrow \alpha.B\beta$ is in closure (I) and $\beta \rightarrow \gamma$ is a production then add $B \rightarrow .\gamma$ to I.

Goto operation

Goto (I, x) is defined to be the closure of the set of all items [$A \rightarrow \alpha X.\beta$] such that [$A \rightarrow \alpha.X\beta$] is in I.

Items

Kernel items: $S' \rightarrow .S$ and all items whose dots are not at the left end

Non-kernel items: Which have their dots at the left end.

Construction of sets of Items

Procedure items (G')
Begin
C: = closure ({[$S' \rightarrow .S$]});
repeat
For each set of items I in C and each grammar symbol x Such that goto (I, x) is not empty and not in C do add goto (I, x) to C;
Until no more sets of items can be added to C, end;

Example: LR (0) items for the grammar

$E' \rightarrow E$
$E \rightarrow E + T/T$
$T \rightarrow T * F/F$
$F \rightarrow (E)/\text{id}$

is given below:
I_0: $E' \rightarrow .E$
$E \rightarrow .E + T$
$E \rightarrow .T$
$T \rightarrow .T * F$

$T \to .F$

$F \to .(E)$

$F \to .\text{id}$

I_1: got (I_0, E)

$E' \to E.$

$E \to E. + T$

I_2: goto (I_0, T)

$E \to T.$

$T \to T. * F$

I_3: goto (I_0, F)

$T \to F.$

I_4: goto $(I_0, ()$

$F \to (.E)$

$E \to .E + T$

$E \to .T$

$E \to .T * F$

$T \to .F$

$F \to .(E)$

$F \to .\text{id}$

I_5: goto (I_0, id)

$F \to \text{id}.$

I_6: got $(I_1, +)$

$E \to E+ .T$

$T \to .T * F$

$T \to .F$

$F \to .(E)$

$F \to .id$

I_7: goto $(I_2, *)$

$T \to T* .F$

$F \to .(E)$

$F \to .id$

I_8: goto (I_4, E)

$F \to (E.)$

I_9: goto (I_6, T)

$E \to E+ T.$

$T \to T.* F$

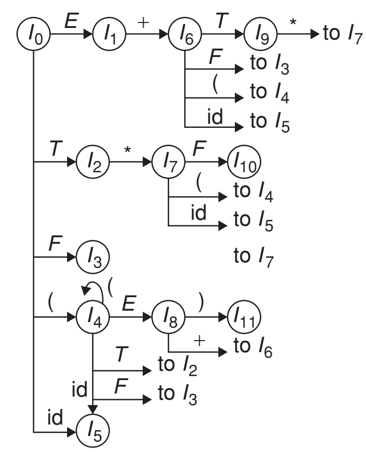
I_{10}: goto (I_7, F)

$T \to T* F.$

I_{11}: goto $(I_8,))$

$F \to (E).$

For viable prefixes construct the DFA as follows:



SLR parsing table construction

1. Construct the canonical collection of sets of LR (0) items for G'.
2. Create the parsing action table as follows:
   (a) If a is a terminal and $[A \to \alpha.a\beta]$ is in I_i, goto $(I_i, a) = I_j$ then action (i, a) to shift j. Here 'a' must be a terminal.
   (b) If $[A \to \alpha.]$ is in I_i, then set action $[i, a]$ to 'reduce $A \to \alpha$' for all a in FOLLOW (A);
   (c) If $[S' \to S.]$ is in I_i then set action $[i, \$]$ to 'accept'.
3. Create the parsing goto table for all non-terminals A, if goto $(I_i, A) = I_j$ then goto $[i, A] = j$.
4. All entries not defined by steps 2 and 3 are made errors.
5. Initial state of the parser contains $S' \to S$.
   The parsing table constructed using the above algorithm is known as SLR (1) table for G.

Note: Every SLR (1) grammar is unambiguous, but every unambiguous grammar is not a SLR grammar.

Example 6: Construct SLR parsing table for the following grammar:

1. $S \to L = R$
2. $S \to R$
3. $L \to * R$
4. $L \to \text{id}$
5. $R \to L$

Solution: For the construction of SLR parsing table, add $S' \to S$ production.

$S' \to S$

$S \to L = R$

$S \to R$

$L \to *R$

$L \to \text{id}$

$R \to L$

LR (0) items will be

I_0: $S' \to .S$

$S \to .L = R$

$S \to .R$

$L \to .{*}R$

$L \to .\text{id}$

$R \to .L$

I_1: goto (I_0, S)

$S' \to S.$

I_2: goto (I_0, L)

$S \to L. = R$

$R \to L.$

I_3: got (I_0, R)

$S \to R.$

I_4: goto (I_0, *)

$L \to {*}.R$

$R \to .L$

$L \to .{*}R$

$L \to .\text{id}$

I_5: goto(I_0, id)

$L \to \text{id}.$

I_6: goto(I_2, =)

$S \to L = .R$

$R \to .L$

$L \to .{*}R$

$L \to .\text{id}$

I_7: goto(I_4, R)

$L \to {*}R.$

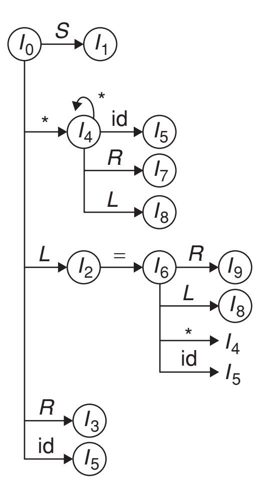
I_8: goto(I_4, L)

$R \to L.$

I_9: goto(I_6, R)

$S \to L = R.$

The DFA of LR(0) items will be



States	Action				Goto		
	=	*	id	$	S	L	R
0		S_4	S_5		1	2	3
1				acc			
2	S_6, r_5			r_5			
3							
4		S_4	S_5			8	7
5							
6		S_4	S_5			8	9
7							
8							
9							

FOLLOW (S) = {\$}
FOLLOW (L) = {=}
FOLLOW (R) = {\$, =}
For action [2, =] = S_6 and r_5
∴ Here we are getting shift – reduce conflict, so it is not SLR (1).

Canonical LR Parsing (CLR)

- To avoid some of invalid reductions, the states need to carry more information.
- Extra information input into a state by including a terminal symbol as a second component of an item.
- The general form of an item

  $[A \to \alpha.\beta, a]$
  Where $A \to \alpha\beta$ is a production.
  a is terminal/right end marker (\$). We will call it as LR (1) item.

LR (1) item

It is a combination of LR (0) items along with look ahead of the item. Here 1 refers to look ahead of the item.

Construction of the sets of LR (1) items Function closure (I):
Begin
Repeat
For each item $[A \to \alpha.B\beta, a]$ in I,
Each production $B \to .\gamma$ in G',
And each terminal b in FIRST (βa)
Such that $[B \to .\gamma, b]$ is not in I do
Add $[B \to .\gamma, b]$ to I;
End;
Until no more items can be added to I;

Example 7: Construct CLR parsing table for the following grammar:

$$S' \to S$$
$$S \to CC$$
$$C \to cC/d$$

Solution: The initial set of items is

I_0: $S' \to .S, \$$
$S \to .CC, \$$
$A \to \alpha.B\beta, a$

Here $A = S$, $\alpha = \in$, $B = C$, $\beta = C$ and $a = \$$
First (βa) is first ($C\$$) = first (C) = $\{c, d\}$
So, add items $[C \to .cC, c]$
$[C \to .cC, d]$

$\therefore$ Our first set I_0: $S' \to .S, \$$
$S \to .CC, \$$
$C \to$ .coca, c/d
$C \to .d, c/d.$

I_1: goto (I_0, X) if $X = S$
$S' \to S., \$$

I_2 : goto (I_0, C)
$S \to C.C, \$$
$C \to .cC, \$$
$C \to .d, \$$
I_3: goto (I_0, c)
$C \to c.C, c/d$
$C \to .cC, c/d$
$C \to .d\ c/d$

I_4: goto (I_0, d)
$C \to d., c/d$

I_5: goto (I_2, C)
$S \to CC., \$$

I_6: goto (I_2, c)
$C \to c.C; \$$
$C \to ..cC, \$$
$C \to ..d, \$$

I_7: goto (I_2, d)
$C \to d.\ \$$

I_8: goto (I_3, C)
$C \to cC., c/d$

I_9: goto (I_6, C)
$C \to cC., \$$

CLR table is:

	Action			Goto	
States	***c***	***1***	**$**	***S***	***C***
I_0	S_3	S_4		1	2
I_1			acc		
I_2	S_6	S_7			5
I_3	S_3	S_4			8
I_4	R_3	r_3			
I_5			r_1		
I_6	S_6	S_7			9
I_7			r_3		
I_8	R_2	r_2			
I_9			r_2		

Consider the string derivation '*dcd*':

$$S \Rightarrow CC \Rightarrow CcC \Rightarrow Ccd \Rightarrow dcd$$

Stack	Input	Action
0	*dcd*$	shift 4
0*d*4	*Cd*$	reduce 3 i.e. $C \to d$
0*C*2	*Cd*$	shift 6
0*C*2*C*6	*D*$	shift 7
0*C*2*C*6*d*7	$	reduce $C \to d$
0*C*2*C*6*C*9	$	reduce $C \to cC$
0*C*2*C*5	$	reduce $S \to CC$
0*S*1	$	

Example 8: Construct CLR parsing table for the grammar:
$S \to L = R$
$S \to R$
$L \to *R$
$L \to id$
$R \to L$

Solution: The canonical set of items is
I_0: $S' \to .S, \$$
$S \to .L = R, \$$
$S \to .R, \$$
$L \to .*\ R, =$ [first (= R$) = {=}]
$L \to$ .id, =
$R \to .L, \$$

I_1: got (I_0, S)
$S' \to S., \$$

I_2: goto (I_0, L)
$S \to L. = R, \$$
$R \to L., \$$

I_3: goto (I_0, R)
$S \to R., \$$

I_4: got (I_0, *)
$L \to *.\ R, =$
$R \to .L, =$
$L \to .*\ R, =$
$L \to$ .id, =
I_5: goto (I_0, id)
$L \to$ id.,=
I_6: goto (I_7, L)
$R \to L., \$$

I_7: goto (I_2, =)
$S \to L = .R,$
$R \to .L, \$$
$L \to .*R, \$$
$L \to$ .id, $

I_8: goto (I_4, R)
$L \to *R., =$

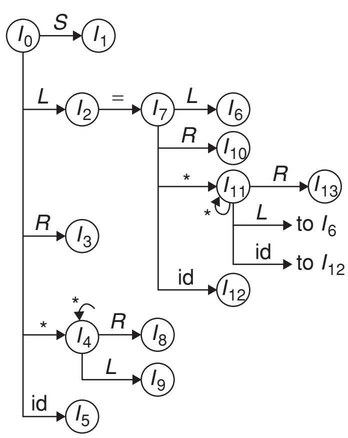
I_9: goto (I_4, L)
$R \rightarrow L., =$

I_{10}: got (I_7, R)
$S \rightarrow L = R., \$$

I_{11}: goto $(I_7, *)$
$L \rightarrow *.R, \$$
$R \rightarrow .L, \$$
$L \rightarrow .*R, \$$
$L \rightarrow .\text{id}, \$$

I_{12}: goto (I_7, id)
$L \rightarrow \text{id}. , \$$

I_{13}: goto (I_{11}, R)
$L \rightarrow *R., \$$



We have to construct CLR parsing table based on the above diagram.

In this, we are going to have 13 states

The shift –reduce conflict in the SLR parser is reduced here.

States	id	*	=	$	S	L	R
0	S_5	S_4			1	2	3
1				acc			
2			S_7	r_5			
3				r_2			
4	S_5	S_4				9	8
5			r_4				
6				r_5			
7	s_{12}	s_{11}				6	10
8			r_3				
9			r_5				
10				r_1			
11	S_{12}	S_{11}					13
12				r_4			
13				r_3			

Stack	Input
0	$Id = id\$$
$0id5$	$= id\$$
$0L2$	$= id\$$
$0L2 = 7$	$id\$$
0L2 = 7! d12	$
$0L2 = 7L6$	$
$0L2 = 7R10$	$
$0S1$ (accept)	$

Every SLR (1) grammar is LR (1) grammar.
CLR (1) will have 'more number of states' than SLR Parser.

LALR Parsing Table

- The tables obtained by it are considerably smaller than the canonical LR table.
- LALR stands for Lookahead LR.
- The number of states in SLR and LALR parsing tables for a grammar G are equal.
- But LALR parsers recognize more grammars than SLR.
- YACC creates a LALR parser for the given grammar.
- YACC stands for 'Yet another Compiler'.
- An easy, but space-consuming LALR table construction is explained below:
  1. Construct $C = \{I_0, I_1, –I_n\}$, the collection of sets of LR (1) items.
  2. Find all sets having the common core; replace these sets by their union
  3. Let $C' = \{J_O, J_1 \text{ --- } J_m\}$ be the resulting sets of LR (1) items. If there is a parsing action conflict then the grammar is not a LALR (1).
  4. Let k be the union of all sets of items having the same core. Then goto $(J, X) = k$
- If there are no parsing action conflicts then the grammar is said to LALR (1) grammar.
- The collection of items constructed is called LALR (1) collection.

Example 9: Construct LALR parsing table for the following grammar:

$S' \rightarrow S$
$S \rightarrow CC$
$C \rightarrow cC/d$

Solution: We already got LR (1) items and CLR parsing table for this grammar.
After merging I3 and I6 are replaced by I36.

I_{36}: $C \rightarrow c.C, c/d/\$$
$C \rightarrow .cC, c/d/\$$
$C \rightarrow .d, c/d/\$$

I_{47}: By merging I_4 and I_7
$C \rightarrow d.\ c/d/\$$

I_{89}: I_8 and I_9 are replaced by I_{89}
$C \rightarrow cC.,\ c/d/\$$

The LALR parsing table for this grammar is given below:

	Action			goto	
State	*c*	*d*	$	*S*	*C*
0	S_{36}	S_{47}		1	2
1			*acc*		
2	S_{36}	S_{47}			5
36	S_{36}	S_{47}			89
47	r_3	R_3	r_3		
5			r_1		
89	r_2	r_2	r_2		

Example: Consider the grammar:

$S' \rightarrow S$
$S \rightarrow aAd$
$S \rightarrow bBd$
$S \rightarrow aBe$
$S \rightarrow bAe$
$A \rightarrow c$
$B \rightarrow c$

Which generates strings acd, bcd, ace and bce

LR (1) items are

I_0: $S' \rightarrow .S,\ \$$
$S \rightarrow .aAd,\ \$$
$S \rightarrow .bBd,\ \$$
$S \rightarrow .aBe,\ \$$
$S \rightarrow .bAe,\ \$$

I_1: goto (I_0, S)
$S' \rightarrow S.,\ \$$

I_2: goto (I_0, a)
$S \rightarrow a.Ad,\ c$
$S \rightarrow a.Be,\ c$
$A \rightarrow .c,d$
$B \rightarrow .c,e$

I_3: goto (I_0, b)
$S \rightarrow b.Bd,\ c$
$S \rightarrow b.Ae,\ c$
$A \rightarrow .c,\ e$
$B \rightarrow .c,\ e$

I_4: goto (I_2, A)
$S \rightarrow aA.d,\ c$

I_5: goto (I_2, B)
$S \rightarrow aB.e,\ c$

I_6: goto (I_2, c)
$A \rightarrow c.,\ d$
$B \rightarrow c.,\ e$

I_7: goto (I_3, c)
$A \rightarrow c.,\ e$
$B \rightarrow c.,\ d$

I_8: goto (I_4, d)
$S \rightarrow aAd.,\ c$

I_9: goto (I_5, e)
$S \rightarrow aBe.,\ c$

If we union I_6 and I_7
$A \rightarrow c.,\ d/e$
$B \rightarrow c.,\ d/e$

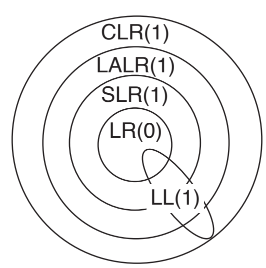
It generates reduce/reduce conflict.

Notes:

1. The merging of states with common cores can never produce a shift/reduce conflict, because shift action depends only on the core, not on the lookahead.
2. SLR and LALR tables for a grammar always have the same number of states (several hundreds) whereas CLR have thousands of states for the same grammar.

Comparison of parsing methods

Method	Item	Goto and Closures	Grammar it Applies to
SLR (1)	LR(0) item	Different from LR(1)	SLR (1) $\subset$ LR(1)
LR (1)	LR(1) item		LR(1) – Largest class of LR grammars
LALR(1)	LR(1) item	Same as LR(1)	LALR(1) $\subset$ LR(1)



Every LR (0) is SLR (1) but vice versa is not true.

Difference between SLR, LALR and CLR parsers

Differences among SLR, LALR and CLR are discussed below in terms of size, efficiency, time and space.

Table 1 *Comparison of parsing methods*

Sl. No.	Factors	SLR Parser	LALR Parser	CLR Parser
1	Size	Smaller	Smaller	Larger
2.	Method	It is based on FOLLOW function	This method is applicable to wider class than SLR	This is most powerful than SLR and LALR.
3.	Syntactic features	Less exposure compared to other LR parsers	Most of them are expressed	Less
4.	Error detection	Not immediate	Not immediate	Immediate
5.	Time and space complexity	Less time and space	More time and space complexity	More time and space complexity

Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Consider the grammar
$S \to a$
$S \to ab$
The given grammar is:
(A) LR (1) only
(B) LL (1) only
(C) Both LR (1) and LL (1)
(D) LR (1) but not LL (1)

2. Which of the following is an unambiguous grammar, that is not LR (1)?
(A) $S \to$ Uab|Vac
$U \to d$
$V \to d$
(B) $S \to$ Uab/Vab/Vac
$U \to d$
$V \to d$
(C) $S \to AB$
$A \to a$
$B \to b$
(D) $S \to Ab$
$A \to a/c$

Common data for questions 3 and 4: Consider the grammar:

$S \to T; S/\in$
$T \to UR$
$U \to x/y/[S]$
$R \to .T/\in$

3. Which of the following are correct FIRST and FOLLOW sets for the above grammar?
(i) FIRST(S) = FIRST (T) = FIRST (U) = $\{x, y, [, \varepsilon\}$
(ii) FIRST (R) = $\{,\varepsilon\}$
(iii) FOLLOW (S) = {], \$}
(iv) FOLLOW (T) = Follow (R) = {;}
(v) FOLLOW (U) = {. ;}
(A) (i) and (ii) only
(B) (ii), (iii), (iv) and (v) only
(C) (ii), (iii) and (iv) only
(D) All the five

4. If an LL (1) parsing table is constructed for the above grammar, the parsing table entry for [$S \to$ [ ] is
(A) $S \to T; S$ (B) $S \to \in$
(C) $T \to UR$ (D) $U \to [S]$

Common data for questions 5 to 7: Consider the augmented grammar
$S \to X$
$X \to (X)/a$

5. If a DFA is constructed for the LR (1) items of the above grammar, then the number states present in it are:
(A) 8 (B) 9
(C) 7 (D) 10

6. Given grammar is
(A) Only LR (1)
(B) Only LL (1)
(C) Both LR (1) and LL (1)
(D) Neither LR (1) nor LL (1)

7. What is the number of shift-reduce steps for input (a)?
(A) 15 (B) 14
(C) 13 (D) 16

8. Consider the following two sets of LR (1) items of a grammar:

$X \to c.X, c/d$	$X \to c.X, \$$
$X \to .cX, c/d$	$X \to .cX, \$$
$X \to d, c/d$	$X \to .d, \$$

Which of the following statements related to merging of the two sets in the corresponding LALR parser is/are FALSE?
1. Cannot be merged since look ahead are different.
2. Can be merged but will result in $S-R$ conflict.
3. Can be merged but will result in $R-R$ conflict.
4. Cannot be merged since goto on c will lead to two different sets.

(A) 1 only (B) 2 only
(C) 1 and 4 only (D) 1, 2, 3 and 4

9. Which of the following grammar rules violate the requirements of an operator grammar?
(i) $A \to BcC$ (ii) $A \to dBC$
(iii) $A \to C/\in$ (iv) $A \to cBdC$

(A) (i) only (B) (i) and
(C) (ii) and (iii) only (D) (i) and (iv) only

10. The FIRST and FOLLOW sets for the grammar:

$$S \rightarrow SS + /SS^*/a$$

(A) First (S) = $\{a\}$
Follow (S) = $\{+, *, \$\}$
(B) First (S) = $\{+\}$
Follow (S) = $\{+, *, \$\}$
(C) First (S) = $\{a\}$
Follow (S) = $\{+, *\}$
(D) First (S) = $\{+, *\}$
Follow (S) = $\{+, *, \$\}$

11. A shift reduces parser carries out the actions specified within braces immediately after reducing with the corresponding rule of the grammar:
$S \rightarrow xxW$ [print '1']
$S \rightarrow y$ [print '2']
$W \rightarrow Sz$ [print '3']
What is the translation of '$x\ x\ x\ x\ y\ z\ z$'?
(A) 1231 (B) 1233
(C) 2131 (D) 2321

12. After constructing the predictive parsing table for the following grammar:
$Z \rightarrow d$
$Z \rightarrow XYZ$
$Y \rightarrow c/\in$
$X \rightarrow Y$
$X \rightarrow a$
The entry/entries for [Z, d] is/are
(A) $Z \rightarrow d$
(B) $Z \rightarrow XYZ$
(C) Both (A) and (B)
(D) $X \rightarrow Y$

13. The following grammar is
$S \rightarrow AaAb/BbBa$
$A \rightarrow \varepsilon$
$B \rightarrow \varepsilon$
(A) LL (1) (B) Not LL (1)
(C) Recursive (D) Ambiguous

14. Compute the FIRST (P) for the below grammar:
$P \rightarrow AQR$be/mn/DE
$A \rightarrow ab/\varepsilon$
$Q \rightarrow q_1q_2/\varepsilon$
$R \rightarrow r_1r_2/\varepsilon$
$D \rightarrow d$
$E \rightarrow e$
(A) $\{m, a\}$ (B) $\{m, a, q_1, r_1, b, d\}$
(C) $\{d, e\}$ (D) $\{m, n, a, b, d, e, q_1, r_1\}$

15. After constructing the LR(1) parsing table for the augmented grammar
$S' \rightarrow S$
$S \rightarrow BB$
$B \rightarrow aB/c$
What will be the action [I_3, a]?
(A) Accept (B) S_7
(C) r_2 (D) S_5

Practice Problems 2

Directions for questions 1 to 19: Select the correct alternative from the given choices.

1. Consider the grammar
$S \rightarrow aSb$
$S \rightarrow aS$
$S \rightarrow \varepsilon$
This grammar is ambiguous by generating which of the following string.
(A) aa (B) $\in$
(C) aaa (D) aab

2. To convert the grammar $E \rightarrow E + T$ into LL grammar
(A) use left factor
(B) CNF form
(C) eliminate left recursion
(D) Both (B) and (C)

3. Given the following expressions of a grammar
$E \rightarrow E \times F/F + E/F$
$F \rightarrow F$? F/id
Which of the following is true?
(A) $\times$ has higher precedence than +
(B) ? has higher precedence than $\times$
(C) + and? have same precedence
(D) + has higher precedence than *

4. The action of parsing the source program into the proper syntactic classes is known as
(A) Lexical analysis
(B) Syntax analysis
(C) Interpretation analysis
(D) Parsing

5. Which of the following is not a bottom up parser?
(A) LALR (B) Predictive parser
(C) CLR (D) SLR

6. A system program that combines separately compiled modules of a program into a form suitable for execution is
(A) Assembler.
(B) Linking loader.
(C) Cross compiler.
(D) None of these.

7. Resolution of externally defined symbols is performed by a
(A) Linker (B) Loader.
(C) Compiler. (D) Interpreter.

8. LR parsers are attractive because
(A) They can be constructed to recognize CFG corresponding to almost all programming constructs.
(B) There is no need of backtracking.
(C) Both (A) and (B).
(D) None of these

9. YACC builds up
(A) SLR parsing table
(B) Canonical LR parsing table
(C) LALR parsing table
(D) None of these

10. Language which have many types, but the type of every name and expression must be calculated at compile time are
(A) Strongly typed languages
(B) Weakly typed languages
(C) Loosely typed languages
(D) None of these

11. Consider the grammar shown below:
$S \to iEtSS'/a/b$
$S' \to eS/\varepsilon$
In the predictive parse table M, of this grammar, the entries $M[S', e]$ and $M[S', \$]$ respectively are
(A) $\{S' \to eS\}$ and $\{S' \to \in\}$
(B) $\{S' \to eS\}$ and $\{\ \}$
(C) $\{S' \to \in\}$ and $\{S' \to \in\}$
(D) $\{S' \to eS, S' \to \varepsilon\}\}$ and $\{S' \to \in\}$

12. Consider the grammar $S \to CC$, $C \to cC/d$.
The grammar is
(A) LL (1)
(B) SLR (1) but not LL (1)
(C) LALR (1) but not SLR (1)
(D) LR (1) but not LALR (1)

13. Consider the grammar
$E \to E + n/E - n/n$
For a sentence $n + n - n$, the handles in the right sentential form of the reduction are
(A) n, $E + n$ and $E + n - n$
(B) n, $E + n$ and $E + E - n$
(C) n, $n + n$ and $n + n - n$
(D) n, $E + n$ and $E - n$

14. A top down parser uses ___ derivation.
(A) Left most derivation
(B) Left most derivation in reverse
(C) Right most derivation
(D) Right most derivation in reverse

15. Which of the following statement is false?
(A) An unambiguous grammar has single leftmost derivation.
(B) An LL (1) parser is topdown.
(C) LALR is more powerful than SLR.
(D) An ambiguous grammar can never be LR (K) for any k.

16. Merging states with a common core may produce ___ conflicts in an LALR parser.
(A) Reduce – reduce
(B) Shift – reduce
(C) Both (A) and (B)
(D) None of these

17. LL (K) grammar
(A) Has to be CFG
(B) Has to be unambiguous
(C) Cannot have left recursion
(D) All of these

18. The I_0 state of the LR (0) items for the grammar
$S \to AS/b$
$A \to SA/a$.
(A) $S' \to .S$
$S \to .As$
$S \to .b$
$A \to .SA$
$A \to .a$
(B) $S \to .AS$
$S \to .b$
$A \to .SA$
$A \to .a$
(C) $S \to .AS$
$S \to .b$
(D) $S \to A$
$A \to .SA$
$A \to .a$

19. In the predictive parsing table for the grammar:
$S \to FR$
$R \to \times S/e$
$F \to \text{id}$
What will be the entry for $[S, \text{id}]$?
(A) $S \to FR$
(B) $F \to \text{id}$
(C) Both (A) and (B)
(D) None of these

Previous Years' Questions

1. Consider the grammar:
$S \to (S) \mid a$
Let the number of states in SLR (1), LR (1) and LALR (1) parsers for the grammar be n_1, n_2 and n_3 respectively. The following relationship holds good: **[2005]**
(A) $n_1 < n_2 < n_3$ (B) $n_1 = n_3 < n_2$
(C) $n_1 = n_2 = n_3$ (D) $n_1 \geq n_3 \geq n_2$

2. Consider the following grammar:
$S \to S * E$
$S \to E$
$E \to F + E$
$E \to F$
$F \to \text{id}$
Consider the following LR (0) items corresponding to the grammar above.
(i) $S \to S * .E$
(ii) $E \to F. + E$
(iii) $E \to F + .E$
Given the items above, which two of them will appear in the same set in the canonical sets-of items for the grammar? **[2006]**
(A) (i) and (ii) (B) (ii) and (iii)
(C) (i) and (iii) (D) None of the above

3. Consider the following statements about the context-free grammar
$G = \{S \to SS, S \to ab, S \to ba, S \to \in\}$
(i) G is ambiguous
(ii) G produces all strings with equal number of a's and b's
(iii) G can be accepted by a deterministic PDA.
Which combination below expresses all the true statements about G? **[2006]**
(A) (i) only (B) (i) and (iii) only
(C) (ii) and (iii) only (D) (i), (ii) and (iii)

4. Consider the following grammar:
$S \to FR$
$R \to *S|\varepsilon$
$F \to \text{id}$
In the predictive parser table, M, of the grammar the entries M[S, id] and M[R, \$] respectively. **[2006]**
(A) $\{S \to FR\}$ and $\{R \to \varepsilon\}$
(B) $\{S \to FR\}$ and $\{\ \}$
(C) $\{S \to FR\}$ and $\{R \to *S\}$
(D) $\{F \to \text{id}\}$ and $\{R \to \varepsilon\}$

5. Which one of the following grammars generates the language $L = \{a^i b^j | i \neq j\}$? **[2006]**
(A) $S \to AC|CB$
$C \to aCb|a|b$
$A \to aA|\in$
$B \to Bb|\in$
(B) $S \to aS|Sb|a|b$
(C) $S \to AC|CB$
$C \to aC|b|\in$
$A \to aA|\in$
$B \to Bb|\in$
(D) $S \to AC|CB$
$C \to aCb|\in$
$A \to aA|a$
$B \to Bb|b$

6. In the correct grammar above, what is the length of the derivation (number of steps starting from S) to generate the string $a^\ell b^m$ with $\ell \neq m$? **[2006]**
(A) max (l, m) + 2
(B) l + m + 2
(C) l + m + 3
(D) max (l, m) + 3

7. Which of the following problems is undecidable? **[2007]**
(A) Membership problem for CFGs.
(B) Ambiguity problem for CFGs.
(C) Finiteness problem for FSAs.
(D) Equivalence problem for FSAs.

8. Which one of the following is a top-down parser? **[2007]**
(A) Recursive descent parser.
(B) Operator precedence parser.
(C) An LR (k) parser.
(D) An LALR (k) parser.

9. Consider the grammar with non-terminals $N = \{S, C, \text{and } S_1\}$, terminals $T = \{a, b, i, t, e\}$ with S as the start symbol, and the following set of rules: **[2007]**
$S \to iCtSS_1/a$
$S_1 \to eS/\varepsilon$
$C \to b$
The grammar is NOT LL (1) because:
(A) It is left recursive
(B) It is right recursive
(C) It is ambiguous
(D) It is not context-free.

10. Consider the following two statements:
P: Every regular grammar is LL (1)
Q: Every regular set has a LR (1) grammar
Which of the following is TRUE? **[2007]**
(A) Both P and Q are true
(B) P is true and Q is false
(C) P is false and Q is true
(D) Both P and Q are false

Common data for questions 11 and 12: Consider the CFG with $\{S, A, B\}$ as the non-terminal alphabet, $\{a, b\}$ as the terminal alphabet, S as the start symbol and the following set of production rules:

$S \to aB$	$S \to bA$
$B \to b$	$A \to a$
$B \to bS$	$A \to aS$
$B \to aBB$	$S \to bAA$

11. Which of the following strings is generated by the grammar? **[2007]**
(A) *aaaabb* (B) *aabbbb*
(C) *aabbab* (D) *abbbba*

12. For the correct answer strings to Q.78, how many derivation trees are there? **[2007]**
(A) 1 (B) 2
(C) 3 (D) 4

13. Which of the following describes a handle (as applicable to LR-parsing) appropriately? **[2008]**
(A) It is the position in a sentential form where the next shift or reduce operation will occur.
(B) It is non-terminal whose production will be used for reduction in the next step.
(C) It is a production that may be used for reduction in a future step along with a position in the sentential form where the next shift or reduce operation will occur.
(D) It is the production *p* that will be used for reduction in the next step along with a position in the sentential form where the right hand side of the production may be found.

14. Which of the following statements are true?
(i) Every left-recursive grammar can be converted to a right-recursive grammar and vice-versa
(ii) All ε-productions can be removed from any context-free grammar by suitable transformations
(iii) The language generated by a context-free grammar all of whose productions are of the form $X \rightarrow w$ or $X \rightarrow wY$ (where, w is a string of terminals and Y is a non-terminal), is always regular
(iv) The derivation trees of strings generated by a context-free grammar in Chomsky Normal Form are always binary trees **[2008]**
(A) (i), (ii), (iii) and (iv) (B) (ii), (iii) and (iv) only
(C) (i), (iii) and (iv) only (D) (i), (ii) and (iv) only

15. An LALR (1) parser for a grammar *G* can have shift-reduce (*S*–*R*) conflicts if and only if **[2008]**
(A) The SLR (1) parser for *G* has *S*–*R* conflicts
(B) The LR (1) parser for *G* has *S*–*R* conflicts
(C) The LR (0) parser for *G* has *S*–*R* conflicts
(D) The LALR (1) parser for *G* has reduce-reduce conflicts

16. $S \rightarrow aSa \mid bSb \mid a \mid b$;
The language generated by the above grammar over the alphabet $\{a, b\}$ is the set of **[2009]**
(A) All palindromes.
(B) All odd length palindromes.
(C) Strings that begin and end with the same symbol.
(D) All even length palindromes.

17. Which data structure in a compiler is used for managing information about variables and their attributes? **[2010]**
(A) Abstract syntax tree
(B) Symbol table
(C) Semantic stack
(D) Parse table

18. The grammar $S \rightarrow aSa|bS|c$ is **[2010]**
(A) LL (1) but not LR (1)
(B) LR (1) but not LR (1)
(C) Both LL (1) and LR (1)
(D) Neither LL (1) nor LR (1)

19. The lexical analysis for a modern computer language such as Java needs the power of which one of the following machine models in a necessary and sufficient sense? **[2011]**
(A) Finite state automata
(B) Deterministic pushdown automata
(C) Non-deterministic pushdown automata
(D) Turing machine

Common data for questions 20 and 21: For the grammar below, a partial LL (1) parsing table is also presented along with the grammar. Entries that need to be filled are indicated as E_1, E_2, and E_3. Is the empty string, \$ indicates end of input, and, *I* separates alternate right hand side of productions

$S \rightarrow a\ A\ b\ B | b\ A\ a\ B |\ e$

$A \rightarrow S$

$B \rightarrow S$

	a	**b**	**$**
S	E_1	E_2	$S \rightarrow e$
A	$A \rightarrow S$	$A \rightarrow S$	Error
B	$B \rightarrow S$	$B \rightarrow S$	E_3

20. The FIRST and FOLLOW sets for the non-terminals A and B are **[2012]**
(A) FIRST $(A) = \{a, b, \varepsilon\}$ = FIRST (B)
FOLLOW $(A) = \{a, b\}$
FOLLOW $(B) = \{a, b, \$\}$
(B) FIRST $(A) = \{a, b, \$\}$
FIRST $(B) = \{a, b, \varepsilon\}$
FOLLOW $(A) = \{a, b\}$
FOLLOW $(B) = \{\$\}$
(C) FIRST $(A) = \{a, b, \varepsilon\}$ = FIRST (B)
FOLLOW $(A) = \{a, b\}$
FOLLOW $(B) = \varnothing$
(D) FIRST $(A) = \{a, b\}$ = FIRST (B)
FOLLOW $(A) = \{a, b\}$
FOLLOW $(B) = \{a, b\}$

21. The appropriate entries for E_1, E_2, and E_3 are **[2012]**
(A) E_1: $S \rightarrow a\ A\ b\ B,\ A \rightarrow S$
E_2: $S \rightarrow b\ A\ a\ B,\ B \rightarrow S$
E_3: $B \rightarrow S$

(B) E_1: $S \to a\,A\,b\,B$, $S \to \varepsilon$
E_2: $S \to b\,A\,a\,B$, $S \to \varepsilon$
E_3: $S \to \in$

(C) E_1: $S \to a\,A\,b\,B$, $S \to \varepsilon$
E_2: $S \to b\,A\,a\,B$, $S \to \varepsilon$
E_3: $B \to S$

(D) E_1: $A \to S$, $S \to \varepsilon$
E_2: $B \to S$, $S \to \varepsilon$
E_3: $B \to S$

22. What is the maximum number of reduce moves that can be taken by a bottom-up parser for a grammar with no epsilon-and unit-production (i.e., of type $A \to \in$ and $A \to a$) to parse a string with n tokens? **[2013]**

(A) $n/2$ (B) $n - 1$
(C) $2n - 1$ (D) 2^n

23. Which of the following is/are undecidable?

(i) G is a CFG. Is $L(G) = \phi$?
(ii) G is a CFG, Is $L(G) = \Sigma^*$?
(iii) M is a Turing machine. Is $L(M)$ regular?
(iv) A is a DFA and N is an NFA. Is $L(A) = L(N)$? **[2013]**

(A) (iii) only
(B) (iii) and (iv) only
(C) (i), (ii) and (iii) only
(D) (ii) and (iii) only

24. Consider the following two sets of LR (1) items of an LR (1) grammar. **[2013]**

$X \to c.X,\ c/d$	$X \to c.X,\ \$$
$X \to .cX,\ c/d$	$X \to .cX,\ \$$
$X \to .d,\ c/d$	$X \to .d,\ \$$

Which of the following statements related to merging of the two sets in the corresponding LALR parser is/are FALSE?

(i) Cannot be merged since look - ahead are different.
(ii) Can be merged but will result in S-R conflict.
(iii) Can be merged but will result in R-R conflict.
(iv) Cannot be merged since goto on c will lead to two different sets.

(A) (i) only (B) (ii) only
(C) (i) and (iv) only (D) (i), (ii), (iii) and (iv)

25. A canonical set of items is given below

$S \to L. > R$
$Q \to R.$

On input symbol < the sset has **[2014]**

(A) A shift–reduce conflict and a reduce–reduce conflict.
(B) A shift–reduce conflict but not a reduce–reduce conflict.
(C) A reduce–reduce conflict but not a shift reduce conflict.
(D) Neither a shift–reduce nor a reduce–reduce conflict.

26. Consider the grammar defined by the following production rules, with two operators * and +

$S \to T * P$
$T \to U | T * U$
$P \to Q + P | Q$
$Q \to Id$
$U \to Id$

Which one of the following is TRUE? **[2014]**

(A) + is left associative, while * is right associative
(B) + is right associative, while * is left associative
(C) Both + and * are right associative.
(D) Both + and * are left associative

27. Which one of the following problems is undecidable? **[2014]**

(A) Deciding if a given context -free grammar is ambiguous.
(B) Deciding if a given string is generated by a given context-free grammar.
(C) Deciding if the language generated by a given context-free grammar is empty.
(D) Deciding if the language generated by a given context free grammar is finite.

28. Which one of the following is TRUE at any valid state in shift-reduce parsing? **[2015]**

(A) Viable prefixes appear only at the bottom of the stack and not inside.
(B) Viable prefixes appear only at the top of the stack and not inside.
(C) The stack contains only a set of viable prefixes.
(D) The stack never contains viable prefixes.

29. Among simple LR (SLR), canonical LR, and look-ahead LR (LALR), which of the following pairs identify the method that is very easy to implement and the method that is the most powerful, in that order? **[2015]**

(A) SLR, LALR
(B) Canonical LR, LALR
(C) SLR, canonical LR
(D) LALR, canonical LR

30. Consider the following grammar G

$S \to F \mid H$
$F \to p \mid c$
$H \to d \mid c$

Where S, F and H are non-terminal symbols, p, d and c are terminal symbols. Which of the following statement(s) is/are correct? **[2015]**

S_1. LL(1) can parse all strings that are generated using grammar G

S_2. LR(1) can parse all strings that are generated using grammar G

(A) Only S_1 (B) Only S_2
(C) Both S_1 and S_2 (D) Neither S_1 nor S_2

31. Match the following: **[2016]**

(P) Lexical analysis (i) Leftmost derivation
(Q) Top down parsing (ii) Type checking
(R) Semantic analysis (iii) Regular expressions
(S) Runtime environments (iv) Activation records

(A) $P \leftrightarrow$ i, $Q \leftrightarrow$ ii, $R \leftrightarrow$ iv, $S \leftrightarrow$ iii
(B) $P \leftrightarrow$ iii, $Q \leftrightarrow$ i, $R \leftrightarrow$ ii, $S \leftrightarrow$ iv
(C) $P \leftrightarrow$ ii, $Q \leftrightarrow$ iii, $R \leftrightarrow$ i, $S \leftrightarrow$ iv
(D) $P \leftrightarrow$ iv, $Q \leftrightarrow$ i, $R \leftrightarrow$ ii, $S \leftrightarrow$ iii

32. A student wrote two context - free grammars **G1** and **G2** for generating a single C-like array declaration. The dimension of the array is at least one.

For example, int a [10] [3];

The grammars use D as the start symbol, and use six terminal symbols int; id [ ] num. **[2016]**

Grammar **G1**	Grammar **G2**
D → **int** L;	D → **int**L;
L → **id** [E	L → **id** E
E → **num**]	E → E [**num**]
E → **num**] [E	E → [**num**]

Which of the grammars correctly generate the declaration mentioned above?

(A) Both **G1** and **G2**
(B) Only **G1**
(C) Only **G2**
(D) Neither **G1** nor **G2**

33. Consider the following grammar:

$$\boxed{\begin{array}{l} P \to xQRS \\ Q \to yz \mid z \\ R \to w \mid \varepsilon \\ S \to y \end{array}}$$

What is FOLLOW (Q)? **[2017]**

(A) $\{R\}$ (B) $\{w\}$
(C) $\{w, y\}$ (D) $\{w, \$\}$

34. Which of the following statements about parser is/are CORRECT? **[2017]**

I. Canonical LR is more powerful than SLR.
II. SLR is more powerful than LALR.
III. SLR is more powerful than Canonical LR.

(A) I only (B) II only
(C) III only (D) I and III only

35. Consider the following expression grammar G :

E – > E – T | T
T – > T + F | F
F – > (E) | id

Which of the following grammars is not left recursive, but is equivalent to G? **[2017]**

(A) E – >E – T | T
T – > T + F | F
F – > (E) | id

(B) E – > TE
E′ – > –TE | ∈
T – > T + F | F
F – > (E) | id

(C) E – > TX
X – > –TX | ∈
T – > FY
Y – > + FY | ∈
F – > (E) | id

(D) E – > TX | (TX)
X – > –TX | +TX | ∈
T – > id

36. Which one of the following statements is FALSE? **[2018]**

(A) Context-free grammar can be used to specify both lexical and syntax rules.
(B) Type checking is done before parsing.
(C) High-level language programs can be translated to different Intermediate Representations.
(D) Arguments to a function can be passed using the program stack.

37. A lexical analyzer uses the following patterns to recognize three tokens T_1, T_2, and T_3 over the alphabet $\{a, b, c\}$.

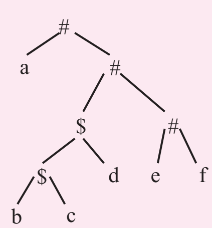
T_1: $a?(b|c)^*a$
T_2: $b?(a|c)^*b$
T_3: $c?(b|a)^*c$

Note that 'x?' means 0 or 1 occurrence of the symbol x. Note also that the analyzer outputs the token that matches the longest possible prefix.

If the string bbaacabc is processed by the analyzer, which one of the following is the sequence of tokens it outputs? **[2018]**

(A) $T_1T_2T_3$ (B) $T_1T_1T_3$
(C) $T_2T_1T_3$ (D) T_3T_3

38. Consider the following parse tree for the expression a#b\$c\$d#e#f, involving two binary operators \$ and #.



Which one of the following is correct for the given parse tree? **[2018]**

(A) \$ has higher precedence and is left associative; # is right associative
(B) # has higher precedence and is left associative; \$ is right associative
(C) \$ has higher precedence and is left associative; # is left associative
(D) # has higher precedence and is right associative; \$ is left associative

Chapter 2

Syntax Directed Translation

LEARNING OBJECTIVES

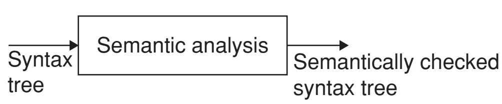
- *Syntax directed translation*
- *Syntax directed definition*
- *Dependency graph*
- *Constructing syntax trees for expressions*
- *Types of SDD's*
- *S-attributed definition*
- *L-attributed definitions*
- *Synthesized attributes on the parser*
- *Syntax directed translation schemes*
- *Bottom up evaluation of inherited attributes*

Syntax Directed Translation

To translate a programming language construct, a compiler may need to know the type of construct, the location of the first instruction, and the number of instructions generated…etc. So, we have to use the term 'attributes' associated with constructs.

An attribute may represent type, number of arguments, memory location, compatibility of variables used in a statement which cannot be represented by CFG alone.

So, we need to have one more phase to do this, i.e., 'semantic analysis' phase.



In this phase, for each production CFG, we will give some semantic rule.

Syntax directed translation scheme

A CFG in which a program fragment called output action (semantic action or semantic rule) is associated with each production is known as Syntax Directed Translation Scheme.

These semantic rules are used to

1. Generate intermediate code.
2. Put information into symbol table.
3. Perform type checking.
4. Issues error messages.

Notes:

1. Grammar symbols are associated with attributes.
2. Values of the attributes are evaluated by the semantic rules associated with production rules.

Notations for Associating Semantic Rules

There are two techniques to associate semantic rules:

Syntax directed definition (SDD) It is high level specification for translation. They hide the implementation details, i.e., the order in which translation takes place.

Attributes + CFG + Semantic rules = Syntax directed definition (SDD).

Translation schemes These schemes indicate the order in which semantic rules are to be evaluated. This is an input and output mapping.

Syntax Directed Definitions

A SDD is a generalization of a CFG in which each grammar symbol is associated with a set of attributes.

There are two types of set of attributes for a grammar symbol.

1. Synthesized attributes
2. Inherited attributes

Each production rule is associated with a set of semantic rules.

Semantic rules setup dependencies between attributes which can be represented by a dependency graph.

The dependency graph determines the evaluation order of these semantic rules.

Evaluation of a semantic rule defines the value of an attribute. But a semantic rule may also have some side effects such as printing a value.

Attribute grammar: An attribute grammar is a syntax directed definition in which the functions in semantic rules 'cannot have side effects'.

Annotated parse tree: A parse tree showing the values of attributes at each node is called an annotated parse tree.

The process of computing the attribute values at the nodes is called annotating (or decorating) of the parse tree.

In a SDD, each production $A \to \propto$ is associated with a set of semantic rules of the form:

$b = f(c_1, c_2, \ldots c_n)$ where

f : A function

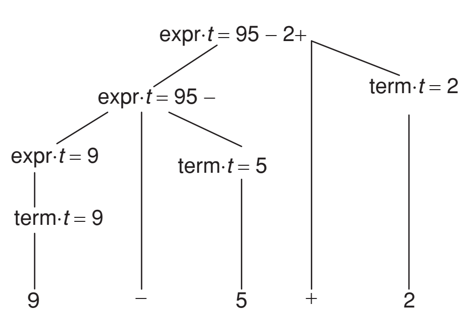
b can be one of the following:

b is a 'synthesized attribute' of A and $c_1, c_2, \ldots c_n$ are attributes of the grammar symbols in $A \to \propto$.

The value of a 'synthesized attribute' at a node is computed from the value of attributes at the children of that node in the parse tree.

Example:

Production	Semantic Rule
expr → expr1 + term	expr.t: = expr1.t||term.t||'+'
expr → expr1 – term	expr.t: = expr1.t||term.t||'–'
expr → term	expr.t: = term.t
term → 0	term.t: = '0'
term → 1	term.t: = '1'
⋮	⋮
term → 9	term.t: = '9'



b is an 'inherited attribute' of one of the grammar symbols on the right side of the production.

An 'inherited attribute' is one whose value at a node is defined in terms of attributes at the parent and/or siblings of that node. It is used for finding the context in which it appears.

Example: An inherited attribute distributes type information to the various identifiers in a declaration.

For the grammar

$D \to$ TL
$T \to$ int
$T \to$ real
$L \to L_1$, id
$L \to$ id

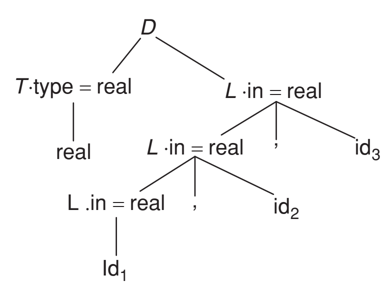
That is, The keyword int or real followed by a list of identifiers.

In this T has synthesized attribute type: T.type. L has an inherited attribute in L.in

Rules associated with L call for procedure add type to the type of each identifier to its entry in the symbol table.

Production	Semantic Rule
$D \to$ TL	L.in = T.type
$T \to$ int	T.type = integer
$T \to$ real	T.type = real
$L \to L_1$, id	addtype L_1.in = L.in(id.entry, L.in)
$L \to$ id	addtype (id.entry, L.in)

The annotated parse tree for the sentence real id_1, id_2, id_3 is shown below:



Synthesized Attribute

The value of a synthesized attribute at a node is computed from the value of attributes at the children of that node in a parse tree. Consider the following grammar:

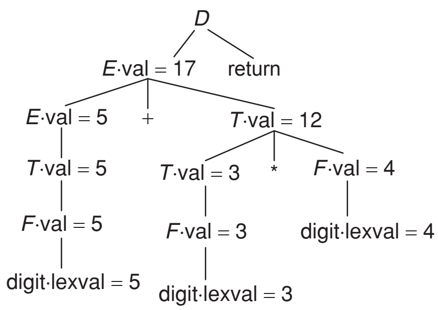
$L \to E_n$
$E \to E_1 + T$
$E \to T$
$T \to T_1 * F$
$T \to F$
$F \to (E)$
$F \to$ digit.

Let us consider synthesized attribute value with each of the non-terminals E, T and F.

Token digit has a synthesized attribute lexical supplied by lexical analyzer.

Production	Semantic Rule
$L \to E_n$	print (E.val)
$E \to E_1 + T$	E.val: = E_1.val + T.val
$E \to T$	E.val: = T_1.val
$T \to T_1 * F$	T.val: = T_1.val*F.val
$T \to F$	T.val: = F.val
$F \to (E)$	F.val: = E.val
$F \to$ digit	F.val: = digit.lexval

The Annotated parse tree for the expression 5 + 3 * 4 is shown below:



Example 1: Consider an example, which shows semantic rules for Infix to posfix translation:

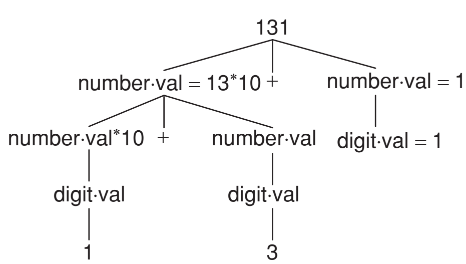
Production	Semantic Rules
expr → expr1 + term	expr.t: = expr1.t||term.t||'+'
expr → expr1 – term	expr.t: = expr1.t||term.t ||'–'
expr → term	expr.t: = term.t
term → 0	term.t: = '0'
⋮	⋮
term→ 9	term.t := '9'

Example 2: Write a SDD for the following grammar to determine number.val.

number → number digit
digit→ 0|1|...9

$$\left\{\begin{array}{l}\text{digit.val := '0'}\\ \text{digit.val := '1'}\\ \quad\vdots\\ \text{digit.val = '9'}\end{array}\right\}$$

number.val:=number.val * 10 + digit.val
Annotated tree for 131 is

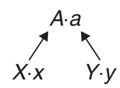


Dependency Graph

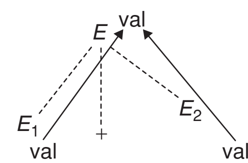
The interdependencies among the attributes at the nodes in a parse tree can be depicted by a directed graph called dependency graph.

- Synthesized attributes have edges pointing upwards.
- Inherited attributes have edges pointing downwards and/or sidewise.

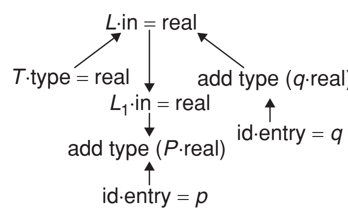
Example 1: $A.a := f(X.x,\ Y.y)$ is a semantic rule for $A \to XY$. For each semantic rule that consists of a procedure call:



Example 2:



Example 3: real p, q;



Evaluation order

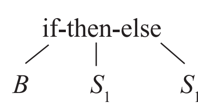
A topological sort of directed acyclic graph is an ordering $m_1, m_2, \ldots m_k$ of nodes of the graph S. t edges go from nodes earlier in the ordering to later nodes.

$m_i \to m_j$ means m_i appears before m_j in the ordering.

If $b: = f(c_1, c_2, \ldots, c_k)$, the dependent attributes $c_1, c_2, \ldots c_k$ are available at node before f is evaluated.

Abstract syntax tree

It is a condensed form of parse tree useful for representing language constructs.
Example



Constructing Syntax Trees for Expressions

Each node in a syntax tree can be implemented as a record with several fields.

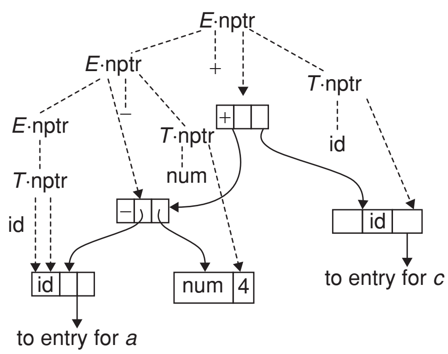
In the node for an operator, one field identifies the operator and the remaining fields contain pointers to the nodes for the operands.

1. mknode (op, left, right)
2. mkleaf (id, entry). Entry is a pointer to symbol table.
3. mkleaf (num, val)

Example:

Production	Semantic Rules
$E \to E_1 + T$	E.nptr := mknode ('+', E_1.nptr, T.nptr)
$E \to E_1 - T$	E.nptr := mknode ('–', E_1.nptr, T.nptr)
$E \to T$	E.nptr := T.nptr
$T \to (E)$	T.nptr := E.nptr
$T \to$ id	T.nptr := mkleaf(id, id.entry)
$T \to$ num	T.nptr := mkleaf(num, num.val)

Construction of a syntax tree for $a - 4 + c$



Types of SDD's

Syntax Directed definitions (SDD) are used to specify syntax directed translations. There are two types of SDD.

1. S-Attributed Definitions
2. L-Attributed Definitions.

S-attributed definitions

- Only synthesized attributes used in syntax direct definition.
- S-attributed grammars interact well with LR (K) parsers since the evaluation of attributes is bottom-up. They do not permit dependency graphs with cycles.

L-attributed definitions

- Both inherited and synthesized attribute are used.
- L-attributed grammar support the evaluation of attributes associated with a production body, dependency–graph edges can go from left to right only.
- Each S-attributed grammar is also a L-attributed grammar.
- L-attributed grammars can be incorporated conveniently in top down parsing.
- These grammars interact well with LL (K) parsers (both table driven and recursive descent).

Synthesized Attributes on the Parser Stack

A translator for an S-attributed definition often be implemented with LR parser generator. Here the stack is implemented by a pair of array state and val.

- Each state entry is pointed to a LR (1) parsing table.
- Each val[i] holds the value of the attributes associated with the node. For $A \to xyz$, the stack will be:

	State	Val
Top →	Z	$Z.z$
	Y	$Y.y$
	X	$X.x$

Example: Consider the following grammar:

$S \to E\,\$$	{print(E.val)}
$E \to E + E$	{E.val := E.val + E.val}
$E \to E * E$	{E.val := E.val * E.val}
$E \to (E)$	{E.val := E.val}
$E \to I$	{I.val := I.val * 10 + digit}
$I \to I$ digit	
$I \to$ digit	{I.val := digit}

Implementation

$S \to E\,\$$	print (val [top])
$E \to E + E$	val[ntop] := val[top] + val[top-2]
$E \to E * E$	val[ntop] := val[top] * val[top-2]
$E \to (E)$	val[ntop] := val[top-1]
$E \to I$	val[ntop] := val[top]
$I \to I$ digit	val[ntop] := 10*val[top] + digit
$I \to$ digit	val[ntop] := digit

L-attributed Definitions

A syntax directed definition is L-attributed if each inherited attribute of X_j, $1 \le j \le n$, on the right side of $A \to X_1 X_2 \ldots X_n$, depends only on

1. The attributes of symbols $X_1, X_2, \ldots, Xj_{-1}$ to the left of X_j in the production.
2. The inherited attributes of A.

Every S-attributed definition is L-attributed, because the above two rules apply only to the inherited attributes.

Syntax directed Translation Schemes

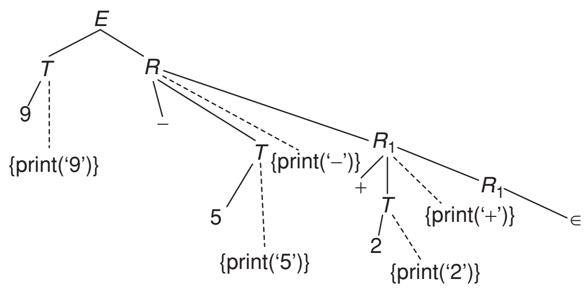
A translation scheme is a CFG in which attributes are associated with grammar symbols and semantic actions are enclosed between braces { } are inserted within the right sides of productions.

Example: $E \to TR$

$R \to$ op T {print (op.lexeme)} $R_1 | \in$

$T \to$ num {print (num.val)}

Using this, the parse tree for 9 – 5 + 2 is



If we have both inherited and synthesized attributes then we have to follow the following rules:

1. An inherited attribute for a symbol on the right side of a production must be computed in an action before that symbol.
2. An action must not refer to a synthesized attribute of a symbol on the right side of the action.
3. A synthesized attribute for the non–terminal on the left can only be computed after all attributes it references, have been computed.

Note: In the implementation of L-attributed definitions during predictive parsing, instead of syntax directed translations, we will work with translation schemes.

Eliminating left recursion from translation scheme

Consider following grammar, which has left recursion

$E \to E + T$ {print ('+') ;}

When transforming the grammar, treat the actions as if they were terminal symbols. After eliminating recursion from the above grammar.

$E \to TR$
$R \to +T$ {print ('+');} R
$R \to \in$

Bottom-up Evaluation of Inherited Attributes

- Using a bottom up translation scheme, we can implement any L-attributed definition based on LL (1) grammar.
- We can also implement some of L-attributed definitions based on LR (1) using bottom up translations scheme.
  - The semantic actions are evaluated during the reductions.
  - During the bottom up evaluation of S-attributed definitions, we have a parallel stack to hold synthesized attributes.

Where are we going to hold inherited attributes?

We will convert our grammar to an equivalent grammar to guarantee the following:

- All embedding semantic actions in our translation scheme will be moved to the end of the production rules.
- All inherited attributes will be copied into the synthesized attributes (may be new non-terminals).

Thus we will evaluate all semantic actions during reductions, and we find a place to store an inherited attribute. The steps are

1. Remove an embedding semantic action S_i, put new non-terminal M_i instead of that semantic action.
2. Put S_i into the end of a new production rule $M_i \to \in$.
3. Semantic action S_i will be evaluated when this new production rule is reduced.
4. Evaluation order of semantic rules is not changed. i.e., if

$$A \to \{S_1\}\ X_1\{S_2\}X_2 \ldots \{S_n\}X_n$$

After removing embedding semantic actions:

$A \to M_1X_1M_2X_2 \ldots M_nX_n$
$M_1 \to \in \{S_1\}$
$M_2 \to \in \{S_2\}$
⋮
$M_n \to \in\ \{S_n\}$

For example,

$E \to TR$
$R \to +T$ {print ('+')} R_1
$R \to \in$
$T \to$ id {print (id.name)}
⇓ remove embedding semantic actions
$E \to TR$
$R \to +TMR_1$
$R \to \in$
$T \to$ id {print (id.name)}
$M \to \in$ {print ('+')}

Translation with inherited attributes

Let us assume that every non-terminal A has an inherited attribute $A.i$ and every symbol X has a synthesized attribute $X.s$ in our grammar.

For every production rule $A \to X_1, X_2 \ldots X_n$, introduce new marker non-terminals

$M_1, M_2, \ldots M_n$ and replace this production rule with $A \to M_1X_1M_2X_2 \ldots M_nX_n$

The synthesized attribute of X_i will not be changed.

The inherited attribute of X_i will be copied into the synthesized attribute of M_i by the new semantic action added at the end of the new production rule

$$M_i \to \in$$

Now, the inherited attribute of X_i can be found in the synthesized attribute of M_i.

$A \to \{B.i = f_1(.\ .)\}\ B\ \{\ c.i = f_2(.\ .)\}\ c\ \{A.s = f_3(.\ .)\}$

⇓

$A \to \{M_1.i = f_1(.\ .)\}\ M_1\ \{B.i = M_1.s\}\ B\ \{M_2.i = f_2(.\ .)\}M_2$
$\{c.i = M_2.S\}\ c\ \{A.s = f_3\ (.\ .)\}$
$M_1 \to \in\ \{M_1.s = M_1.i\}$
$M_2 \to \in\ \{M_2.s = M_2.i\}$

Exercises

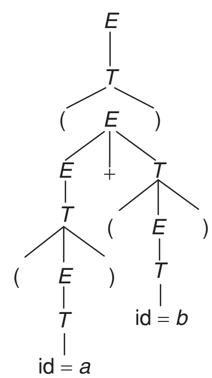
Practice Problems I

Directions for questions 1 to 13: Select the correct alternative from the given choices.

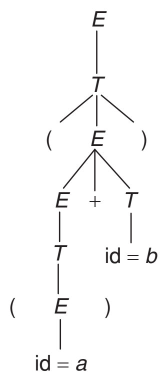
1. The annotated tree for input $((a) + (b))$, for the rules given below is

Production	Semantic Rule
$E \to E + T$	$ $ = mknode ('+', $1, $3)
$E \to E–T$	$ $ = mknode ('–', $1, $3)
$E \to T$	$ $ = $1;
$T \to (E)$	$ $ = $2;
$T \to$ id	$ $ = mkleaf (id, $1)
$T \to$ num	$ $ = mkleaf (num, $1)

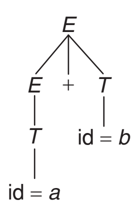
(A)



(B)



(C)



(D) None of these

2. Let synthesized attribute val give the value of the binary number generated by S in the following grammar.
$S \to L\ L$
$S \to L$
$L \to LB$
$L \to B$
$B \to 0$
$B \to 1$
Input 101.101, S.val = 5.625
use synthesized attributes to determine S.val
Which of the following are true?
(A) $S \to L_1.L_2$ {S.val = L_1.val + L_2.val/ (2**L_2.bits)
|L {S.val = L.val; S.bits = L.bits}
(B) $L \to L_1\ B$ {L.val = L_1.val*2 + B.val;
L.bits = L_1.bits + 1}
|B {L.val = B.val; L.bits = 1}
(C) $B \to 0$ {B.val = 0}
|1 {B.val = 1}
(D) All of these

3. Which of the following productions with translation rules converts binary number representation into decimal.

(A)

Production	Semantic Rule
$B \to 0$	B.trans = 0
$B \to 1$	B.trans = 1
$B \to B_0$	B_1.trans = B_2.trans*2
$B \to B_1$	B_1.trans = B_2.trans * 2 + 1

(B)

Production	Semantic Rule
$B \to 0$	B.trans = 0
$B \to B_0$	B_1.trans = B_2.trans*4

(C)

Production	Semantic Rule
$B \to 1$	B.trans = 1
$B \to B_1$	B_1.trans = B_2.trans*2

(D) None of these

4. The grammar given below is

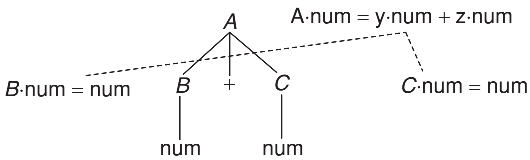
Production	Semantic Rule
$A \to$ LM	L.i := l(A. i)
	M.i := m(L.s)
	A.s := f(M.s)
$A \to$ QR	R.i := r(A.i)
	Q.i := q(R.s)
	A.s := f(Q.s)

(A) A L-attributed grammar
(B) Non-L-attributed grammar
(C) Data insufficient
(D) None of these

5. Consider the following syntax directed translation:
$S \to aS$ {$m := m + 3$; print (m);}
|bS {$m: = m$*2; print (m) ;}
|$\in$ {$m: = 0$;}
A shift reduce parser evaluate semantic action of a production whenever the production is reduced.
If the string is = $a\ a\ b\ a\ b\ b$ then which of the following is printed?
(A) 0 0 3 6 9 12
(B) 0 0 0 3 6 9 12
(C) 0 0 0 3 6 9 12 15
(D) 0 0 3 9 6 12

6. Which attribute can be evaluated by shift reduce parser that execute semantic actions only at reduce moves but never at shift moves?
(A) Synthesized attribute
(B) Inherited attribute
(C) Both (a) and (b)
(D) None of these

7. Consider the following annotated parse tree:



Which of the following is true for the given annotated tree?

(A) There is a specific order for evaluation of attribute on the parse tree.
(B) Any evaluation order that computes an attribute 'A' after all other attributes which 'A' depends on, is acceptable.
(C) Both (A) and (B)
(D) None of these.

Common data for questions 8 and 9: Consider the following grammar and syntax directed translation.

$E \to E + T$	E_1.val = E_2.val + T.val
$E \to T$	E.val = T.val
$T \to T^*P$	T_1.val = T_2.val * P.val * P.num
$T \to P$	T.val = P.val * P.num
$P \to (E)$	P.val = E.val
$P \to 0$	P.num = 1
	P.val = 2
$P \to 1$	P.num = 2
	P.val = 1

8. What is E.val for string 1*0?
(A) 8 (B) 6
(C) 4 (D) 12

9. What is the E.val for string 0 * 0 + 1?
(A) 8 (B) 6
(C) 4 (D) 12

10. Consider the following syntax directed definition:

Production	Semantic Rule
$S \to b$	$S.x = 0$ $S.y = 0$
$S \to S_1$ I	$S.x = S_1.x + I.dx$ $S.y = S_1.y + I.dy$
$I \to$ east	$I.dx = 1$ $I.dy = 0$
$I \to$ north	$I.dx = 0$ $I.dy = 1$
$I \to$ west	$I.dx = -1$ $I.dy = 0$
$I \to$ south	$I.dx = 0$ $I.dy = -1$

If Input = begin east south west north, after evaluating this sequence what will be the value of $S.x$ and $S.y$?
(A) (1, 0) (B) (2, 0)
(C) (–1, –1) (D) (0, 0)

11. What will be the values $s.x$, $s.y$ if input is 'begin west south west'?
(A) (–2, –1)
(B) (2, 1)
(C) (2, 2)
(D) (3, 1)

12. Consider the following grammar:

$S \to E$	S.val = E.val
	E.num = 1
$E \to E^*T$	E_1.val = 2 * E_2.val + 2 * T.val
	E_2.num = E_1.num + 1
	T.num = E_1.num + 1
$E \to T$	E.val = T.val
	T.num = E.num + 1
$T \to T + P$	T_1.val = T_2.val + P.val
	T_2.num = T_1.num + 1
	P.num = T_1.num + 1
$T \to P$	T.val = P.val
	P.num = T.num + 1
$P \to (E)$	P.val = E.val
$P \to i$	$\begin{Bmatrix} E.\text{num} = P.\text{num} \\ P.\text{val} = I \mid P.\text{num} \end{Bmatrix}$

Which attributes are inherited and which are synthesized in the above grammar?

(A) Num attribute is inherited attribute. Val attribute is synthesized attribute.
(B) Num is synthesized attribute. Val is inherited attribute.
(C) Num and val are inherited attributes.
(D) Num and value are synthesized attributes.

13. Consider the grammar with the following translation rules and E as the start symbol.

$E \to E_1 @ T$ {E.value = E_1.value*T.value}
 |T {E.value = T.value}
$T \to T_1$ and F {T.value = T_1.value + F.value}
 |F {T.value = F.value}
$F \to$ num {F.value = num.value}

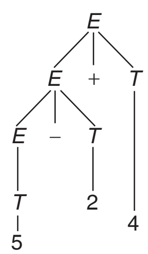
Compute E.value for the root of the parse tree for the expression: 2 @ 3 and 5 @ 6 and 4
(A) 200 (B) 180
(C) 160 (D) 40

Practice Problems 2

Directions for questions 1 to 10: select the correct alternative from the given choices.

1. Consider the following Tree:

Production	Meaning
$E \rightarrow E_1 + T$	$E.t = E_1.t{*}T.t$
$E \rightarrow E_1 - T$	$E.t = E_1.t + T.t$
$E \rightarrow T$	$E.t = T.t$
$t \rightarrow 0$	$T.t =$ ‘0’
$t \rightarrow 5$	$T.t =$ ‘5’
$t \rightarrow 2$	$T.t =$ ‘2’
$t \rightarrow 4$	$T.t =$ ‘4’



After evaluation of the tree the value at the root will be:
(A) 28 (B) 32
(C) 14 (D) 7

2. The value of an inherited attribute is computed from the values of attributes at the ________
(A) Sibling nodes (B) Parent of the node
(C) Children node (D) Both (A) and (B)

3. Consider an action translating expression:

expr → expr + term {print (‘+’)}
expr → expr – term {print (‘–’)}
expr → → term
term → 1 {print (‘1’)}
term → 2 {print (‘2’)}
term → 3 {print (‘3’)}

Which of the following is true regarding the above translation expression?
(A) Action translating expression represents infix notation.
(B) Action translating expression represents prefix notation.
(C) Action translating expression represents postfix notation.
(D) None of these

4. In the given problem, what will be the result after evaluating 9 – 5 + 2?
(A) + – 9 5 2 (B) 9 – 5 + 2
(C) 9 5 – 2+ (D) None of these

5. In a syntax directed translation, if the value of an attribute node is a function of the values of attributes of children, then it is called:
(A) Synthesized attribute (B) Inherited attribute
(C) Canonical attributes (D) None of these

6. Inherited attribute is a natural choice in:
(A) Keeping track of variable declaration
(B) Checking for the correct use of L-values and R-values.
(C) Both (A) and (B)
(D) None of these

7. Syntax directed translation scheme is desirable because
(A) It is based on the syntax
(B) Its description is independent of any implementation.
(C) It is easy to modify
(D) All of these

8. A context free grammar in which program fragments, called semantic actions are embedded within right side of the production is called,
(A) Syntax directed translation
(B) Translation schema
(C) Annotated parse tree
(D) None of these

9. A syntax directed definition specifies translation of construct in terms of:
(A) Memory associated with its syntactic component
(B) Execution time associated with its syntactic component
(C) Attributes associated with its syntactic component
(D) None of these

10. If an error is detected within a statement, the type assigned to the Statement is:
(A) Error type (B) Type expression
(C) Type error (D) Type constructor

Previous Years’ Questions

Common data for questions 1 (A) and 1 (B): Consider the following expression grammar. The semantic rules for expression evaluation are stated next to each grammar production: **[2005]**

$E \rightarrow$ number $\quad E$.val = number.val
$|E$ ‘+’ $E \quad E^{(1)}$.val = $E^{(2)}$.val + $E^{(3)}$.val
$|E \rightarrow E \quad E^{(1)}$.val = $E^{(2)}$.val × $E^{(3)}$.val

1. (A) The above grammar and the semantic rules are fed to a yacc tool (which is an LALR (1) parser generator) for parsing and evaluating arithmetic expressions. Which one of the following is true about the action of yacc for the given grammar?
(A) It detects recursion and eliminates recursion
(B) It detects reduce-reduce conflict, and resolves

(C) It detects shift-reduce conflict, and resolves the conflict in favor of a shift over a reduce action.
(D) It detects shift-reduce conflict, and resolves the conflict in favor of a reduce over a shift action.

(B) Assume the conflicts in Part (A) of this question are resolved and an LALR (1) parser is generated for parsing arithmetic expressions as per the given grammar. Consider an expression 3 × 2 + 1. What precedence and associativity properties does the generated parser realize?
(A) Equal precedence and left associativity; expression is evaluated to 7
(B) Equal precedence and right associativity; expression is evaluated to 9
(C) Precedence of '×' is higher than that of '+', and both operators are left associative; expression is evaluated to 7
(D) Precedence of '+' is higher than that of '×', and both operators are left associative; expression is evaluated to 9

2. In the context of abstract-syntax-tree (AST) and control-flow-graph (CFG), which one of the following is TRUE? **[2015]**
(A) In both AST and CFG, let node N_2 be the successor of node N_1. In the input program, the code corresponding to N_2 is present after the code corresponding to N_1.
(B) For any input program, neither AST nor CFG will contain a cycle.
(C) The maximum number of successors of a node in an AST and a CFG depends on the input program.
(D) Each node in AST and CFG corresponds to at most one statement in the input program.

3. Consider the following Syntax Directed Translation Scheme (SDTS), with non-terminals {S, A} and terminals {**a, b**}. **[2016]**

$S \to aA$	{ print 1 }
$S \to a$	{ print 2 }
$A \to Sb$	{ print 3 }

Using the above SDTS, the output printed by a bottom-up parser, for the input **aab** is:
(A) 1 3 2 (B) 2 2 3
(C) 2 3 1 (D) syntax error

4. Which one of the following grammars is free from *left recursion*? **[2016]**
(A) $S \to AB$
$A \to Aa/b$
$B \to c$
(B) $S \to Ab/Bb/c$
$A \to Bd/\varepsilon$
$B \to e$
(C) $S \to Aa/B$
$A \to Bb/Sc/\varepsilon$
$B \to d$
(D) $S \to Aa/Bb/c$
$A \to Bd/\varepsilon$
$B \to Ae/\varepsilon$

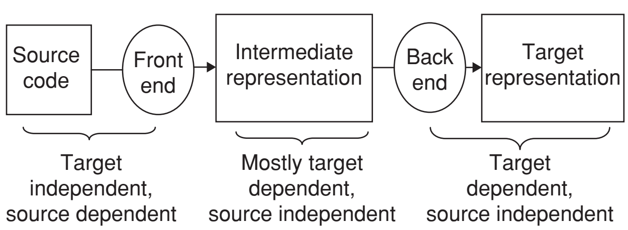
Intermediate Code Generation

LEARNING OBJECTIVES

- *Introduction*
- *Directed Acyclic Graphs (DAG)*
- *Three address code*
- *Symbol table operations*
- *Assignment statements*
- *Boolean expression*
- *Flow control of statements*
- *Procedure calls*
- *Code generation*
- *Next use information*
- *Run-time storage management*
- *DAG representations of basic blocks*
- *Peephole optimization*

Introduction

In the analysis–synthesis model, the front end translates a source program into an intermediate representation (IR). From IR the back end generates target code.



There are different types of intermediate representations:

- High level IR, i.e., AST (Abstract Syntax Tree)
- Medium level IR, i.e., Three address code
- Low level IR, i.e., DAG (Directed Acyclic Graph)
- Postfix Notation (Reverse Polish Notation, RPN).

In the previous sections already we have discussed about AST and RPN.

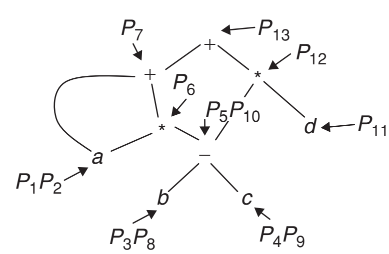
Benefits of Intermediate code generation: The benefits of ICG are

1. We can obtain an optimized code.
2. Compilers can be created for the different machines by attaching different backend to existing front end of each machine.
3. Compilers can be created for the different source languages.

Directed acyclic graphs for expression: (DAG)

- A DAG for an expression identifies the common sub expressions in the given expression.
- A node N in a DAG has more than one parent if N represents a common sub expression.
- DAG gives the compiler, important clues regarding the generation of efficient code to evaluate the expressions.

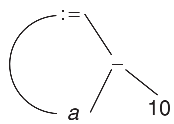
Example 1: DAG for $a + a*(b - c) + (b - c)*d$



P_1 = makeleaf (id, a)
P_2 = makeleaf (id, a) = P_1
P_3 = makeleaf (id, b)
P_4 = makeleaf (id, c)
P_5 = makenode (–, P_3, P_4)
P_6 = makenode (*, P_1, P_5)
P_7 = makenode (+, P_1, P_6)
P_8 = makeleaf (id, b) = P_3
P_9 = makeleaf (id, c) = P_4
P_{10} = makenode (–, P_8, P_9) = P_5

P_{11} = makeleaf (id, d)
P_{12} = makenode (*, P_{10}, P_{11})
P_{13} = makenode (+, P_7, P_{12})

Example 2: $a: = a - 10$



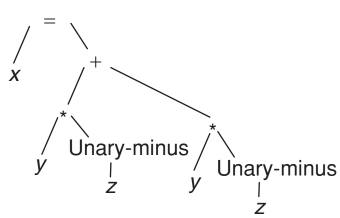
THREE-ADDRESS CODE

In three address codes, each statement usually contains 3 addresses, 2 for operands and 1 for the result.

Example: $-x = y$ OP z

- x, y, z are names, constants or complier generated temporaries,
- OP stands for any operator. Any arithmetic operator (or) Logical operator.

Example: Consider the statement $x = y * -z + y* -z$



The corresponding three address code will be like this:

Syntax Tree	DAG
$t_1 = -z$	$t_1 = -z$
$t_2 = y * t_1$	$t_2 = y * t_1$
$t_3 = -z$	$t_5 = t_2 + t_2$
$t_4 = y * t_3$	$X = t_5$
$t_5 = t_4 + t_2$	
$X = t_5$	

The postfix notation for syntax tree is: xyz unaryminus *yz unaryminus *+=.

- Three address code is a 'Linearized representation' of syntax tree.
- Basic data of all variables can be formulated as syntax directed translation. Add attributes whenever necessary.

Example: Consider below *SDD* with following specifications:
E might have E. place and E.code
E.place: the name that holds the value of E.
E.code: the sequence of intermediate code starts evaluating E.
Let Newtemp: returns a new temporary variable each time it is called.
New label: returns a new label.
Then the SDD to produce three–address code for expressions is given below:

Production	Semantic Rules
$S \rightarrow$ id ASN E	S. code = E.code \\ gen (ASN, id.place, E.place) E. Place = newtemp ();
$E \rightarrow E_1$ PLUS E_2	E. code = E_1. code || E_2. code || gen (PLUS, E. place, E_1. place, E_2. place); E. place = newtemp();
$E \rightarrow E_1$MUL E_2	E. code = E_1. code || E_2.code || gen (MUL, E. place, E_1. place, E_2. place); E. Place = Newtemp();
$E \rightarrow$ UMINUS E_1	E. code = E_1 code || gen (NEG, E. Place, E_1. place); E. code = E_1.code
$E \rightarrow$ LP E_1 RP	E. Place = E_1. Place
$E \rightarrow$ IDENT	E.place = id. place E. code = empty.list ();

Types of Three Address Statement

Assignment

- Binary assignment: $x: = y$ OP z Store the result of y OP z to x.
- Unary assignment: $x: =$ op y Store the result of unary operation on y to x.

Copy

- Simple Copy $x: = y$ Store y to x
- Indexed Copy $x: = y[i]$ Store the contents of $y[i]$ to x
- $x[i]:= y$ Store y to $(x + i)$th address.

Address and pointer manipulation

$x : = \&y$ Store address of y to x

$x : = *y$ Store the contents of y to x

$*x : = y$ Store y to location pointed by x .

Jump

- Unconditional jump:- goto L, jumps to L.
- Conditional:

```
if (x relop y)
goto L1;
else
```

```
{
goto L2;
}
```

Where relop is <, < =, >, > = , = or ≠.

Procedure call

Param x_1;

Param x_2;

.

.

.

Param x_n;

Call p, n, x;	Call procedure p with n parameters and store the result in x.
return x	Use x as result from procedure.

Declarations

- Global x, n_1, n_2: Declare a global variable named x at offset n_1 having n_2 bytes of space.
- Proc x, n_1, n_2: Declare a procedure x with n_1 bytes of parameter space and n_2 bytes of local variable space.
- Local x, m: Declare a local variable named x at offset m from the procedure frame.
- End: Declare the end of the current procedure.

Adaption for object oriented code

- $x = y$ field z: Lookup field named z within y, store address to x
- Class x, n_1, n_2: declare a class named x with n_1 bytes of class variables and n_2 bytes of class method pointers.
- Field x, n: Declare a field named x at offset n in the class frame.
- New x: Create a new instance of class name x.

Implementation of Three Address Statements

Three address statements can be implemented as records with fields for the operator and the operands. There are 3 types of representations:

1. Quadruples
2. Triples
3. Indirect triples

Quadruples

A quadruple has four fields: op, arg1, arg2 and result.

- Unary operators do not use arg2.
- Param use neither arg2 nor result.
- Jumps put the target label in result.
- The contents of the fields are pointers to the symbol table entries for the names represented by these fields.
- Easier to optimize and move code around.

Example 1: For the expression $x = y * - z + y * - z$, the quadruple representation is

	OP	Arg1	Arg2	Result
(0)	Uminus	z		t_1
(1)	*	y	t_1	t_2
(2)	Uminus	z		t_3
(3)	*	y	t_3	t_4
(4)	+	t_2	t_4	t_5
(5)	=	t_5		x

Example 2: Read (x)

	Op	Arg1	Arg2	Result
(0)	Param	x		
(1)	Call	READ	(x)	

Example 3: WRITE ($A*B$, x +5)

	OP	Arg1	Arg2	Result
(0)	*	A	B	t_1
(1)	+	x	5	t_2
(2)	Param	t_1		
(3)	Param	t_2		
(4)	Call	Write	2	

Triples

Triples have three fields: OP, arg1, arg2.

- Temporaries are not used and instead references to instructions are made.
- Triples are also known as two address code.
- Triples takes less space when compared with Quadruples.
- Optimization by moving code around is difficult.
- The DAG and triple representations of expressions are equivalent.
- For the expression $a = y* - z + y*-z$ the Triple representation is

	Op	Arg1	Arg2
(0)	Uminus	z	
(1)	*	y	(0)
(2)	Uminus	z	
(3)	*	y	(2)
(4)	+	(1)	(3)
(5)	=	a	(4)

Array – references

Example: For A [I]: = B, the quadruple representation is

	Op	Arg1	Arg2	Result
(0)	[ ] =	A	I	T_1
(1)	=	B		T_2

The same can be represented by Triple representation also.

[] = is called L-value, specifies the address to an element.

	Op	Arg1	Arg2
(0)	[ ] =	*A*	*I*
(1)	=	(0)	*B*

Example 2: $A := B[I]$

	Op	Arg1	Arg2
(0)	= [ ]	*B*	*I*
(1)	=	*A*	(0)

= [ ] is called r-value, specifies the value of an element.

Indirect Triples

- In indirect triples, pointers to triples will be there instead of triples.
- Optimization by moving code around is easy.
- Indirect triples takes less space when compared with Quadruples.
- Both indirect triples and Quadruples are almost equally efficient.

Example: Indirect Triple representation of 3-address code

	Statement
(0)	(14)
(1)	(15)
(2)	(16)
(3)	(17)
(4)	(18)
(5)	(19)

	Op	Arg1	Arg2
(14)	Uminus	*z*	
(15)	*	*y*	(14)
(16)	Uminus	*z*	
(17)	*	*y*	(16)
(18)	+	(15)	(17)
(19)	=	*x*	(18)

Symbol Table Operations

Treat symbol tables as objects.

- Mktable (previous);
  - create a new symbol table.
  - Link it to the symbol table previous.
- Enter (table, name, and type, offset)
  - insert a new identifier name with type and offset into table
  - Check for possible duplication.
- Add width (table, width);
  - increase the size of symbol table by width.
- Enterproc (table, name, new table)
  - Enter a procedure name into table.
  - The symbol table of name is new table.
- Lookup (name, table);
  - Check whether name is declared in the symbol table, if it is in the table then return the entry.

Example:

Declaration → $M_1 D$

$M_1 \rightarrow \in$ `{TOP (Offset): = 0 ;}`

$D \rightarrow D$ ID

$D \rightarrow$ id: T `{enter (top (tblptr), id.name, T.type top (offset)); top (offset): = top (offset) + T. width ;}`

$T \rightarrow$ integer `{T.type : = integer; T. width: = 4 :}`

$T \rightarrow$ double `{T.type: = double; T.width = 8 ;}`

$T \rightarrow * T_1$ `{T. type: = pointer (T. type); T.width = 4;}`

Need to remember the current offset before entering the block, and to restore it after the block is closed.

Example: Block → begin M4 Declarations statements end `{pop (tblptr); pop (offset) ;}`

$M_4 \rightarrow \in$ `{t: = mktable (top (tblptr); push (t, tblptr); push (top (offset), offset) ;`

Can also use the block number technique to avoid creating a new symbol table.

Field names in records

- A record declaration is treated as entering a block in terms of offset is concerned.
- Need to use a new symbol table.

Example: $T \rightarrow$ record M_5 D end

```
{T. type: = (top (tblptr));
 T. width = top (offset);
 pop (tblptr);
 pop (offset) ;}
```

$M_5 \rightarrow \in$

```
{t: = mktable (null);
push (t, tblptr);
push {(o, offset) ;}
```

Assignment Statements

Expressions can be of type integer, real, array and record. As part of translation of assignments into three address code, we show how names can be looked up in the symbol table and how elements of array can be accessed.

Code generation for assignment statements gen ([address # 1], [assignment], [address #2], operator, address # 3);

Variable accessing Depending on the type of [address # i], generate different codes.

Types of [address # i]:

- Local temp space
- Parameter
- Local variable
- Non-local variable
- Global variable
- Registers, constants,…

Error handling routine error – msg (error information);

The error messages can be written and stored in other file. Temp space management:

- This is used for generating code for expressions.
- newtemp (): allocates a temp space.
- freetemp (): free t if it is allocated in the temp space

Label management

- This is needed in generating branching statements.
- newlabel (): generate a label in the target code that has never been used.

Names in the symbol table

$S \to$ id: $= E$ {p: = lookup (id-name, top (tblptr));
If p is not null then gen (p, ":=", E.place);
Else error ("var undefined", id. Name) ;}
$E \to E_1 + E_2$ {E. place = newtemp ();
gen (E.place, ": = ", E_1.place, "+", E_2.Place); free temp (E1.pace); freetemp (E2. place) ;}
$E \to -E_1$ {E. place = newtemp ();
gen (E.place, ": =", "uminus", E_1.place);
Freetemp (E_1. place ;)}
$E \to (E_1)$ {E. place = E_1. place ;}
$E \to$ id {p: = lookup (id.name, top (tblptr);
If p ≠ null then E.place = p. place else error ("var undefined", id. name) ;}

Type conversions

Assume there are only two data types: integer, float.

For the expression,

$$E \to E_1 + E_2$$

If E_1. type = E_2. type then
generate no conversion code
E.type = E_1. type;

Else

E.type = float;
temp1 = newtemp ();
If E_1. type = integer then
gen (temp1,':=' int - to - float, E_1.place);
gen (*E*,':=' temp1, '+', E_2.place);

Else

gen (temp1,':=' int - to - float, E_2. place);
gen (*E*,':=' temp1, '+', E_1. place);
Free temp (temp1);

Addressing array elements

Let us assume

low: lower bound
w: element data width

Start_addr: starting address

1D Array: A[i]

- Start_addr + (i – low)* $w = i * w$ + (start_addr – low *w)
- The value called base, (start_addr – low * w) can be computed at compile time and then stored at the symbol table.

Example: array [–8 …100] of integer.

To declare [–8] [–7] … [100] integer array in Pascal.

2D Array A [i_1, i_2]

Row major order: row by row. A [i] means the ith row.

1st row A [1, 1]
A [1, 2]

2nd row A [2, 1]
A [2, 2]
A [i, j] = A [i] [j]

Column major: column by column.

A [1, 1] ¦ A [1, 2]
A [2, 1] ¦ A [2, 2]
1st Column 2nd column

Address for A [i_1, i_2]:

Start _ addr + ((i_1 – low$_1$) *n_2 + (i_2 – low$_2$))*w

Where low$_1$ and low$_2$ are the lower bounds of i_1 and i_2. n_2 is the number of values that i_2 can take. High$_2$ is the upper bound on the valve of i_2. n_2 = high$_2$ – low$_2$ + 1

We can rewrite address for A [i_1, i_2] as (($i_1 \times n_2$) + i_2) × w + (start _ addr - ((low$_1 \times n_2$) + low$_2$) × w). The value (start _ addr – low$_1 \times n_2 \times w$ – low$_2 \times w$) can be computed at compiler time and then stored in the symbol table.

Multi-Dimensional Array A [i_1, i_2,…i_k]

Address for A [i_1, i_2,…i_k]

$$= i_1 * \pi_{i=2}^{k} {}^{n_i} + i_2 * \pi_{i=3}^{k} {}^{n_i} + \cdots + i_k \Big) * w$$
$$+ \Big(start\_addr - low_1 * w * \pi_{i=2}^{k} ni$$
$$- low_2 * w * \pi_{i=3}^{k} {}^{n_i} - \cdots - low_k * w \Big)$$

It can be computed incrementally in grammar rules:

f (1) = i_1;
f (j) = f (j –1) * n_j + i_j;
f (k) is the value we wanted to compute.

Attributes needed in the translation scheme for addressing array elements:

Elegize: size of each element in the array

Array: a pointer to the symbol table entry containing information about the array declaration.

Ndim: the current dimension index

Base: base address of this array

Place: where a variable is stored.

Limit (array, n) = n_m is the number of elements in the mth coordinate.

Translation scheme for array elements

Consider the grammar

$S \to L := E$
$E \to L$

$L \rightarrow$ id

$L \rightarrow$ [Elist]

Elist$\rightarrow$ Elist$_1$, E

Elist$\rightarrow$ id [E]

$E \rightarrow$ id

$E \rightarrow E + E$

$E \rightarrow (E)$

- $S \rightarrow L{:}=E$ `{if L. offset = null then /* L is a simple id */ gen (L. place, ":=", E.place);`
```
Else
gen (L. place, "[", L. offset, "]",":=", E.place);
```
- $E \rightarrow E_1 + E_2$ `{E.place = newtemp ();`
```
gen (E. place, ":=", E1.place, "+", E2.place) ;}
```
- $E \rightarrow (E_1)$ `{E.place= E1.place}`
- $E \rightarrow L$ `{if L. offset = null then /* L is a simple id */ E.place:= L .place);`
```
Else begin
E.place:=newtemp();
gen (E.place, ":=",L.place, "[",L.offset, ']");
end }
```
- $L \rightarrow$ id `{P! = lookup (id.name, top (tblptr));`
```
If P ≠ null then
Begin
L.place: = P.place:
L.offset:= null;
End
Else
Error ("Var underfined", id. Name) ;}
```
- $L \rightarrow$ Elist `{L. offset: = newtemp ();`
```
gen (L. offset, ":=", Elist.elesize,
"*", Elist.place );
freetemp (Elist.place);
L.Place := Elist . base ;}
```
- Elist$\rightarrow$ Elist$_1$, E `{t: =newtemp (); m: = Elist1.ndim+1;`
```
gen (t, ":=" Elist1.place, "*", limit (Elist1.array, m));
Gen (t, ":=", t"+", E.place); freetemp (E.place);
Elist.array: = Elist.array;
Elist.place:= t; Elist.ndim:= m ;}
```
Elist $\rightarrow$ id [E `{Elist.Place:= E.place; Elist.ndim:=1;`
```
P! = lookup (id.name, top (tblptr)); check for id errors;
Elist.elesize:= P.size; Elist.base: = p.base;
Elist.array:= p.place ;}
```
- $E \rightarrow$ id `{P:= lookup (id,name, top (tblptr);`

```
Check for id errors; E. Place: = Populace ;}
```

Boolean Expressions

There are two choices for implementation of Boolean expressions:

1. Numerical representation
2. Flow of control

Numerical representation

Encode true and false values.
Numerically, 1:true 0: false.
Flow of control: Representing the value of a Boolean expression by a position reached in a program.

Short circuit code: Generate the code to evaluate a Boolean expression in such a way that it is not necessary for the code to evaluate the entire expression.

- If a_1 or a_2
  a_1 is true then a_2 is not evaluated.
- If a_1 and a_2
  a_1 is false then a_2 is not evaluated.

Numerical representation

$E \rightarrow$ id$_1$ relop id2

```
{B.place:= newtemp ();
gen ("if", id1.place, relop.op, id2.place,"goto", next stat +3);
gen (B.place,":=", "0");
gen ("goto", nextstat+2);
gen (B.place,":=", "1")'}
```

Example 1: Translate the statement (if $a < b$ or $c < d$ and $e < f$) without short circuit evaluation.

```
100: if a < b goto 103
101: t1:= 0
102: goto 104
103: t1:= 1 /* true */
104: if c < d goto 107
105: t2:= 0 /* false */
106: goto 108
107: t2:= 1
108: if e < f goto 111
109: t3:= 0
110: goto 112
111: t3 := 1
112: t4 := t2 and t3
113: t3:= t1 or t4
```

Flow of Control Statements

$B \rightarrow$ id$_1$ relop id$_2$

```
{
B.true: = newlabel ();
B.false:= newlabel ();
B.code:= gen ("if", id1. relop, id2, "goto",
```

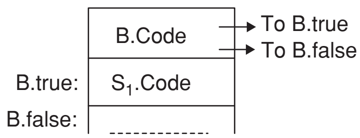
```
B.true, "else", "goto", B. false) ||
gen (B.true, ":")
}
```

$S \rightarrow$if B then S_1 S.code:= B.code || S_1 .code ||gen (B.false, ':')

|| is the code concatenation operator.

1. **If – then implementation:**

   $S \rightarrow$if B then $S1$ `{gen (Befalls," :");}`



2. **If – then – else**

   $P \rightarrow S$ `{S.next:= newlabel ();`

   `P.code:= S.code || gen (S.next," :")}`

   $S \rightarrow$ if B then S_1 else S_2 `{S`$_1$`.next:= S.next;`

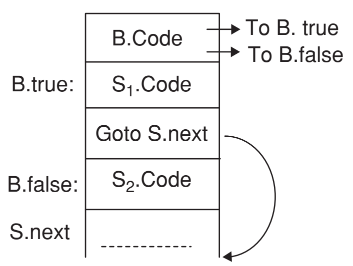
   `S`$_2$`.next:= S.next;`

   `Secede: = B.code || S`$_1$`.code ||.`

   `Gen ("goto" S.next) || B. false," :")`

   `||S`$_2$`.code}`

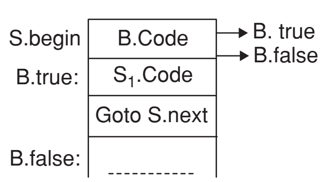
   Need to use inherited attributes of S to define the attributes of S_1 and S_2



3. **While loop:**

   $B \rightarrow$ id$_1$ relop id$_2$ B.true:= newlabel ();
   B.false:= newlabel ();
   B.code:=gen ('if', id.relop,
   id$_2$, 'goto', B.true 'else', 'goto', B. false) ||
   gen (B.true ':');

   $S \rightarrow$ while B do S_1 S.begin:= newlabel ();
   S.code:=gen (S.begin,':')||
   B.code||S1.code || gen
   ('goto', S.begin) || gen (B.false, ':');



4. **Switch/case statement:**

   The c - like syntax of switch case is

```
switch epr {
case V [1]: S [1]
.
.
.
case V [k]: S[k]
default: S[d]
        }
```

Translation sequence

- Evaluate the expression.
- Find which value in the list matches the value of the expression, match default only if there is no match.
- Execute the statement associated with the matched value.

How to find the matched value? The matched value can be found in the following ways:

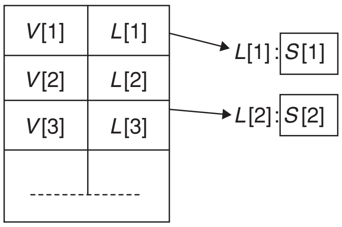
1. Sequential test
2. Lookup table
3. Hash table
4. Back patching

Two different translation schemes for sequential test are shown below:

1. Code to evaluate E into t
   Goto test
   $L[i]$: code for S [1]
   goto next

   $L[k]$: code for $S[k]$
   goto next
   $L[d]$: code for $S[d]$
   Go to next test:
   If $t = V$ [1]: goto L [1]
   .
   .
   .
   goto L[d]
   Next:
2. Can easily be converted into look up table
   If $t <> V[i]$ goto L [1]
   Code for S [1]
   goto next
   ....
   L [1]: if $t <> V$ [2] goto L [2]
   Code for S [2]
   Goto next
   L [k – 1]: if $t <> V$ [k] goto L[k]
   Code for S[k]
   Goto next
   .
   .
   .
   L[k]: code for S[d]
   Next:

Use a table and a loop to find the address to jump



3. **Hash table:** When there are more than two entries use a hash table to find the correct table entry.
4. **Back patching:**
   - Generate a series of branching statements with the targets of jumps temporarily left unspecified.
   - To determine label table: each entry contains a list of places that need to be back patched.
   - Can also be used to implement labels and gotos.

Procedure Calls

- Space must be allocated for the activation record of the called procedure.
- Arguments are evaluated and made available to the called procedure in a known place.
- Save current machine status.
- When a procedure returns:
  - Place returns value in a known place.
  - Restore activation record.

Example: $S \rightarrow$ call id (Elist)

```
{for each item P on the queue Elist.
Queue do gen ('PARAM', q);
gen ('call:', id.place) ;}
```

Elist $\rightarrow$ Elist, E {append E.place to the end of Elist.queue}

Elist $\rightarrow$ E {initialize Elist.queue to contain only E.place}

Use a queue to hold parameters, then generate codes for params.

Code for E_1, store in t_1

.

.

.

Code for E_k, store in t_k

PARAM $t1$

:

.

.

PARAM tk

Call P

Terminology:

Procedure declaration:

Parameters, formal parameters

Procedure call:

Arguments, actual parameters.

The values of a variable: $x = y$

r – value: value of the variable, i.e., on the right side of assignment. Ex: y, in above assignment.

l – value: The location/address of the variable, i.e., on the leftside of assignment. Ex: x, in above assignment.

There are different modes of parameter passing

1. call-by-value
2. call-by-reference
3. call-by-value-result (copy-restore)
4. call-by-name

Call by value

Calling procedure copies the r values of the arguments into the called procedure's Activation Record.

Changing a formal parameter has no effect on the actual parameter.

Example: void add (int C)

```
{
C = C+ 10;
printf ('\nc = %d', &C);
}
main ()
{
int a = 5;
printf ('a=%d', &a);
add (a);
printf ('\na = %d', &a);
}
```

In main a will not be affected by calling add (a)

It prints $a = 5$

$a = 5$

Only the value of C in add ( ) will be changed to 15.

Usage:

1. Used by PASCAL and C++ if we use non-var parameters.
2. The only thing used in C.

Advantages:

1. No aliasing.
2. Easier for static optimization analysis.
3. Faster execution because of no need for redirecting.

Call by reference

Calling procedure copies the l-values of the arguments into the called procedure's activation record. i.e., address will be passed to the called procedure.

- Changing formal parameter affects the corresponding actual parameter.
- It will have some side effects.

Example:

```
void add (int *c)
{
*c = *c + 10;
printf('\nc=%d', *c);
```

```
}
void main()
{
int a = 5;
printf ('\na = %d', a);
add (&a);
printf ('\na = %d', a);
```

output: a = 5
c = 15
a = 15

That is, here the actual parameter is also modified.

Advantages

1. Efficiency in passing large objects.
2. Only need to copy addresses.

Call-by-value-result

Equivalent to call-by-reference except when there is aliasing. That is, the program produces the same result, but not the same code will be generated.

Aliasing: Two expressions that have the same l-values are called aliases. They access the same location from different places.

Aliasing happens through pointer manipulation.

1. Call by reference with global variable as an argument.
2. Call by reference with the same expression as argument twice.

Example: test (x,y,x)

Advantages:

1. If there is no aliasing, we can implement it by using call – by – reference for large objects.
2. No implicit side effect if pointers are not passed.

Call by-name

used in Algol.

- Procedure body is substituted for the call in calling procedure.
- Each occurrence of a parameter in the called procedure is replaced with the corresponding argument.
- Similar to macro expansion.
- A parameter is not evaluated unless its value is needed during computation.

Example:

```
void show (int x)
{
for (int y = 0; y < 10; y++)
x++;
}
main ()
{
int j;
j = -1;
show (j);
}
Actually it will be like this
main ()
{
int j;
j = - 1;
For (in y= 0; y < 10; y ++)
x ++;
}
```

- Instead of passing values or address as arguments, a function is passed for each argument.
- These functions are called **thunks.**
- Each time a parameter is used, the thunk is called, then the address returned by the thunk is used.

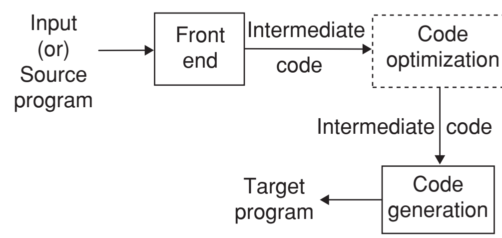
$y = 0$: use return value of thunk for y as the ℓ-value.

Advantages

- More efficient when passing parameters that are never used.
- This saves lot of time because evaluating unused parameter takes a longtime.

Code Generation

Code generation is the final phase of the compiler model.



The requirements imposed on a code generator are

1. Output code must be correct.
2. Output code must be of high quality.
3. Code generator should run efficiently.

Issues in the Design of a Code Generator

The generic issues in the design of code generators are

- Input to the code generator
- Target programs
- Memory Management
- Instruction selection
- Register Allocation
- Choice of Evaluation order

Input to the code generator

Intermediate representation with symbol table will be the input for the code generator.

- High Level Intermediate representation

Example: Abstract Syntax Tree (AST)

- Medium – level intermediate representation

Example: control flow graph of complex operations

- Low – Level Intermediate representation

Example: Quadruples, DAGS

- Code for abstract stack machine, i.e., postfix code.

Target programs

The output of the code generator is the target program. The output may take on a variety of forms:

1. Absolute machine language
2. Relocatable machine language
3. Assembly language

Absolute machine language

- Final memory area for a program is statically known.
- Hard coded addresses.
- Sufficient for very simple systems.

Advantages:

- Fast for small programs
- No separate compilation

Disadvantages: Can not call modules from other languages/ compliers.

Relocatable code It Needs

- Relocation table
- Relocating linker + loader (or) runtime relocation in Memory management Unit (MMU).

Advantage: More flexible.

Assembly language Generates assembly code and use an assembler tool to convert this to binary (object) code. It needs (i) assembler (ii) linker and loader.

Advantage: Easier to handle and closer to machine.

Memory management

Mapping names in the source program to addresses of data objects in runtime memory is done by the front end and the code generator.

- A name in a three address statement refers to a symbol entry for the name.
- Stack, heap, garbage collection is done here.

Instruction selection

Instruction selection depends on the factors like

- Uniformity
- Completeness of the instruction
- Instruction speed
- Machine idioms

- Choose set of instructions equivalent to intermediate representation code.
- Minimize execution time, used registers and code size.

Example: $x = y + z$ in three address statements:

MOV y, R_0 / * load y into R_0 * /

ADD z, R_0

MOV R_0, x /* store R_0 into x*/

Register allocation

- Instructions with register operands are faster. So, keep frequently used values in registers.
- Some registers are reserved.

Example: *SP*, *PC* … etc.
Minimize number of loads and stores.

Evaluation order

- The order of evaluation can affect the efficiency of the target code.
- Some orders require fewer registers to hold intermediate results.

Target Machine

Lets us assume, the target computer is

- Byte addressable with 4 bytes per word
- It has n general purpose registers $R_0, R_1, R_2, \ldots R_{n-1}$
- It has 2 address instructions of the form

  OP source, destination
  [cost: 1 + added]

Example: The op may be MOV, ADD, MUL.
Generally cost will be like this

Source	Destination	Cost
Register	Register	1
Register	Memory	2
Memory	Register	2
Memory	Memory	3

Addressing modes:

Mode	Form	Address	Cost
Absolute	M	M	2
Register	R	R	1
Indexed	C(R)	C+contents(R)	2
Indirect register	*R	Contents (R)	1
Indirect indexed	*C(R)	Contents (C+contents (R))	2

Example: $x: = y - z$

MOV y, R0 $\rightarrow$ cost = 2

SUB z, R0 $\rightarrow$ cost = 2

MOV R_0, $x \rightarrow$ cost = 2

6

Runtime Storage Management

Storage Organization

To run a compiled program, compiler will demand the operating system for the block of memory. This block of memory is called runtime storage.

This run time storage is subdivided into the generated target code, Data objects and Information which keeps track of procedure activations.

The fixed data (generated code) is stored at the statically determined area of the memory. The Target code is placed at the lower end of the memory.

The data objects are stored at the statically determined area as its size is known at the compile time. Compiler stores these data objects at statically determined area because these are compiled into target code. This static data area is placed on the top of the code area.

The runtime storage contains stack and the heap. Stack contains activation records and program counter, data object within this activation record are also stored in this stack with relevant information.

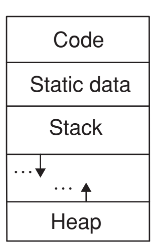
The heap area allocates the memory for the dynamic data (for example some data items are allocated under the program control)

The size of stack and heap will grow or shrink according to the program execution.

Activation Record

Information needed during an execution of a procedure is kept in a block of storage called an activation record.

- Storage for names local to the procedures appears in the activation record.
- Each execution of a procedure is referred as activation of the procedure.
- If the procedure is recursive, several of its activation might be alive at a given time.
- Runtime storage is subdivided into
  1. Generated target code area
  2. Data objects area
  3. Stack
  4. Heap



- Sizes of stack and heap can change during program execution.

For code generation there are two standard storage allocations:

1. **Static allocation:** The position of an activation record in memory is fixed at compile time.
2. **Stack allocation:** A new activation record is pushed on to the stack for each execution of the procedure.

The record is poped when the activation ends.

Control stack The control stack is used for managing active procedures, which means when a call occurs, the execution of activation is interrupted and status information of the stack is saved on the stack.

When control is returned from a call, the suspended activation is resumed after storing the values of relevant registers it also includes program counter which sets to point immediately after the call.

The size of stack is not fixed.

Scope of declarations Declaration scope refers to the certain program text portion, in which rules are defined by the language.

Within the defined scope, entity can access legally to declared entities.

The scope of declaration contains immediate scope always. Immediate scope is a region of declarative portion with enclosure of declaration immediately.

Scope starts at the beginning of declaration and scope continues till the end of declaration. Whereas in the over loadable declaration, the immediate scope will begin, when the callable entity profile was determined.

The visible part refers text portion of declaration, which is visible from outside.

Flow Graph

A flow graph is a graph representation of three address statement sequences.

- Useful for code generation algorithms.
- Nodes in the flow graph represents computations.
- Edges represent flow of control.

Basic Blocks

Basic blocks are sequences of consecutive statements in which flow of control enters at the beginning and leaves at the end without a halt or branching.

1. First determine the set of leaders
   - First statement is leader
   - Any target of goto is a leader
   - Any statement that follows a goto is a leader.
2. For each leader its basic block consists of the leader and all statements up to next leader.

Initial node: Block with first statement is leader.

Example: consider the following fragment of code that computes dot product of two vectors x and y of length 10.

begin

Prod: = 0;

i: = 1;
repeat
begin
Prod: = Prod + x [i] * y [i];
i: = i + 1;
end
until i < = 10;
end

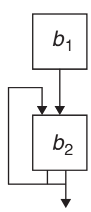
B_1

(1)	Prod : = 0
(2)	I: = 1

B_2

(3)	t_1:= 4*i
(4)	t_2: =x[t_1]
(5)	t_3: =4 * i
(6)	t_4: =y [t_3]
(7)	t_5: =t_2* t_4
(8)	t_6; =Prod + t_5
(9)	Prod := t_6
(10)	t_7: = i+1
(11)	i:= t_7
(12)	if i < = 10 goto (3)

∴The flow graph for this code will be



Here b_1 is the initial node/block.

- Once the basic blocks have been defined, a number of transformations can be applied to them to improve the quality of code.
    1. **Global:** Data flow analysis
    2. **Local:**
        - Structure preserving transformations
        - Algebraic transformations
- Basic blocks compute a set of expressions. These expressions are the values of the names live on exit from the block.
- Two basic blocks are equivalent if they compute the same set of expressions.

Structure preserving transformations:

1. *Common sub-expression elimination:*

$$\begin{array}{l} a := b + c \\ b := a - d \\ c := b + c \\ d := a - d \end{array} \Rightarrow \begin{array}{l} a := b + c \\ b := a - d \\ c := b + c \\ d := b \end{array}$$

2. *Dead code elimination:* Code that computes values for names that will be dead i.e., never subsequently used can be removed.
3. *Renaming of temporary variables*
4. *Interchange of two independent adjacent statements*

Algebraic Transformations

Algebraic identities represent other important class optimizations on basic blocks. For example, we may apply arithmetic identities, such as $x + 0 = 0 + x = x$,

$$x * 1 = 1 * x = x$$
$$x - 0 = x$$
$$x/1 = x$$

Next-Use Information

- Next-use info used in code generation and register allocation.
- Remove variables from registers if not used.
- Statement of the form $A = B$ or C defines A and uses B and C.
- Scan each basic block backwards.
- Assume all temporaries are dead or exit and all user variables are live or exit.

Algorithm to compute next use information

Suppose we are scanning
i: x: = y op z
in backward scan

- attach to i, information in symbol table about x, y, z.
- set x to not live and no next-use in symbol table
- set y and z to be live and next-use in symbol table.

Consider the following code:
1: $t_1 = a * a$
2: $t_2 = a * b$
3: $t_3 = 2 * t_2$
4: $t_4 = t_1 + t_2$
5: $t_5 = b * b$
6: $t_6 = t_4 + t_5$
7: $x = t_6$
Statements:
7: no temporary is live
6: t_6: use (7) t_4 t_5 not live
5: t_5: use (6)
4: t_4: use (6), t_1 t_3 not live
3: t_3: use (4) t_2 not live
2: t_2: use (3)
1: t_1: use (4)
Symbol Table:
t_1 dead use in 4

t_2 dead use in 3
t_3 dead use in 4
t_4 dead use in 6
t_5 dead use in 6
t_6 dead use in 7
The six temporaries in the basic block can be packed into two locations t_1 and t_2:
1: $t_1 = a * a$
2: $t_2 = a * b$
3: $t_2 = 2 * t_2$
4: $t_1 = t_1 + t_2$
5: $t_2 = b * b$
6: $t_1 = t_1 + t_2$
7: $x = t_1$

Code Generator

- Consider each statement
- Remember if operand is in a register
- Descriptors are used to keep track of register contents and address for names
- There are 2 types of descriptors
  1. Register Descriptor
  2. Address Descriptor

Register Descriptor

Keep track of what is currently in each register. Initially all registers are empty.

Address Descriptors

- Keep track of location where current value of the name can be found at runtime.
- The location might be a register, stack, memory address or a set of all these.

Issues in design of code generation The issues in the design of code generation are

1. Intermediate representation
2. Target code
3. Address mapping
4. Instruction set.

Intermediate Representation It is represented in post fix, 3-address code (or) quadruples and syntax tree (or) DAG.

Target Code The Target Code could be absolute code, relocatable machine code (or) assembly language code. Absolute code will execute immediately as it is having fixed address relocatable, requires linker and loader to get the code from appropriate location for the assembly code, assemblers are required to convert it into machine level code before execution.

Address mapping In this, mapping is defined between intermediate representations to target code address.

It is based on run time environment like static, stack or heap.

Instruction set It should provide a complete set in such a way that all its operations can be implemented.

Code Generation Algorithm

For each three address statement $x = y$ op z do

- Invoke a function getreg to determine location L where x must be stored. Usually L is a register.
- Consult address descriptor of y to determine y'. Prefer a register for y'. If value of y is not already in L generate MOV y', L.
- Generate
  OP z', L
  Again prefer a register for z. Update address descriptor of x to indicate x is in L. If L is a register update its descriptor to indicate that it contains x and remove x from all other register descriptors.
- If current value of y and/or z have no next use and are dead or exit from block and are in registers then change the register descriptor to indicate that it no longer contain y and /or z.

Function getreg

1. If y is in register and y is not live and has no next use after $x = y$ OP z then return register of y for L.
2. Failing (1) return an empty register.
3. Failing (2) if x has a next use in the block or OP requires register then get a register R, store its contents into M and use it.
4. Else select memory location x as L.

Example: $D: = (a - b) + (a - c) + (a - c)$

Stmt	Code Generated	reg desc	addr desc
$t = a - b$	MOV a, R_0 SUB b, R_0	R_0 contains t	t in R_0
$u = a - c$	MOV a, R_1 SUB c, R_1	R_0 contains t R_1 contains u	t in R_0 u in R_1
$v = t + u$	ADD R_1, R_0	R_0 contains v R_1 contains u	u in R_0 v in R_0
$d = v + u$	ADD R_1, R_0 MOV R_0,d	R_o contains d	d in R_0 d in R_0 and memory

Conditional Statements

Machines implement conditional jumps in 2 ways:

1. Based on the value of the designated register (R)
   Branch if values of R meets one of six conditions.
   (i) Negative (ii) Zero
   (iii) Positive (iv) Non-negative
   (v) Non-zero (vi) Non-positive

Example: Three address statement: if $x < y$ goto z
It can be implemented by subtracting y from x in R, then jump to z if value of R is negative.

2. Based on a set of **condition codes** to indicate whether last quantity computed or loaded into a location is negative (or) Zero (or) Positive.
   - compare instruction set codes without actually computing the value.

Example: CMP x, y
CJL Z.

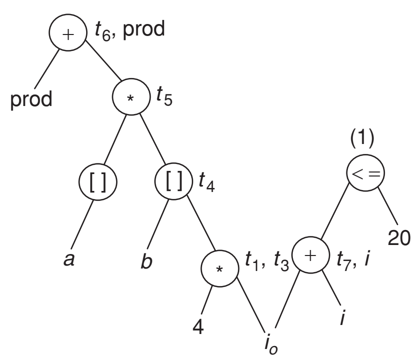
- Maintains a condition code descriptor, which tells the name that last sets the condition codes.

Example: $X: = y + z$
If $x < 0$ goto z
By
MOV y, R_o
ADD z, R_o
MOV R_o, x
CJN z.

DAG Representation of Basic Blocks

- DAGS are useful data structures for implementing transformations on basic blocks.
- Tells, how value computed by a statement is used in subsequent statements.
- It is a good way of determining common sub expressions.
- A DAG for a basic block has following labels on the nodes:
  - Leaves are labeled by unique identifiers, either variable names or constants.
  - Interior nodes are labeled by an operator symbol.
  - Nodes are also optionally given as a sequence of identifiers for labels.

Example: 1: $t_1 := 4 * i$
2: $t_2 := a\ [t_1]$
3: $t_3 := 4 * i$
4: $t_4 := b\ [t_3]$
5: $t_5 := t_2 * t_4$
6: $t_6 :=$ prod $+ t_5$
7: prod: $= t_6$
8: $t_7 := i + 1$
9: $i = t_7$
10: if $i < = 20$ got (1)

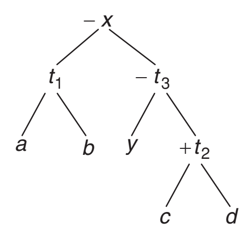


Code Generation from DAG:

$S_1 = 4 * i$	$S_1 = 4 * i$
$S_2 = \text{add(A)} - 4$	$S_2 = \text{add(A)} - 4$
$S_3 = S_2\ [S_1]$	$S_3 = S_2\ [S_1]$
$S_4 = 4 * i$	
$S_5 = \text{add(B)} - 4$	$S_5 = \text{add(B)} - 4$
$S_6 = S_5[S_4]$	$S_6 = S_5[S_4]$
$S_7 = S_3 * S_6$	$S_7 = S_3 * S_6$
$S_8 = \text{prod} + S_7$	$\text{prod} = \text{prod} + S_7$
$\text{prod} = S_8$	
$S_9 = I + 1$	
$I = S_9$	$I = I + 1$
if $I < = 20$ got (1)	if $I < = 20$ got (1)

Rearranging order of the code

Consider the following basic block
$t_1 := a + b$
$t_2 := c + d$
$t_3 := e - t_2$
$x = t_1 - t_3$ and its DAG



Three address code for the DAG:
(Assuming only two registers are available)
MOV a, R_o
ADD b, R_o
MOV c, R_1
MOV R_o, t_1 Register Spilling
MOV e, R_o Register Reloading
SUB R_1, R_o
MOV t_1, R_1
SUB R_o, R_1
MOV R_1, x

Rearranging the code as
$t_2 := c + d$
$t_3 := e - t_2$
$t_1 := a + b$
$x = t_1 - t_3$
The rearrangement gives the code:
MOV c, R_o
ADD d, R_o
MOV e, R_1
SUB R_o, R_1

MOV a, R_o
ADD b, R_o
SUB R_1, R_0
MOV R_1, x

Error detection and Recovery The errors that arise while compiling

1. Lexical errors
2. Syntactic errors
3. Semantic errors
4. Run-time errors

Lexical errors If the variable (or) constants are declared (or) defined, not according to the rules of language, special symbols are included which were not part of the language, etc is the lexical error.

Lexical analyzer is constructed based on pattern recognizing rules to form a token, when a source code is made into tokens and if these tokens are not according to rules then errors are generated.

Consider a c program statement
printf ('Hello World');

Main printf, (, ', Hello world,' ,),; are tokens.

Printf is not recognizable pattern, actually it should be printf. It generates an error.

Syntactic error These errors include semi colons, missing braces etc. which are according to language rules.

The parser reports the errors

Semantic errors This type of errors arises, when operation is performed over incompatible type of variables, double declaration, assigning values to undefined variables etc.

Runtime errors The Runtime errors are the one which are detected at runtime. These include pointers assigned with NULL values and accessing a variable which is out of its boundary, unlegible arithmetic operations etc.

After the detection of errors. The following recovery strategies should be implemented.

1. Panic mode recovery
2. Phrase level recovery
3. Error production
4. Global correction.

Peephole Optimization

- Target code often contains redundant instructions and suboptimal constructs.
- Improving the performance of the target program by examining a short sequence of target instructions (peephole) and replacing these instructions by a shorter or faster sequence is peephole optimization.
- The peephole is a small, moving window on the target program. Some well known peephole optimizations are

1. Eliminating redundant instructions
2. Eliminating unreachable code
3. Flow of control optimizations or Eliminating jumps over jumps
4. Algebraic simplifications
5. Strength reduction
6. Use of machine idioms

Elimination of Redundant Loads and stores

Example 1: (1) MOV R_o, a
(2) MOV a, R_o

We can delete instruction (2), because the value of a is already in R_0.

Example 2: Load x, R_0
Store R_0, x

If no modifications to R_0/x then store instruction can be deleted

Example 3: (1) Load x, R_0
(2) Store R_0, x

Example 4: (1) store R_0, x
(2) Load x, R_0

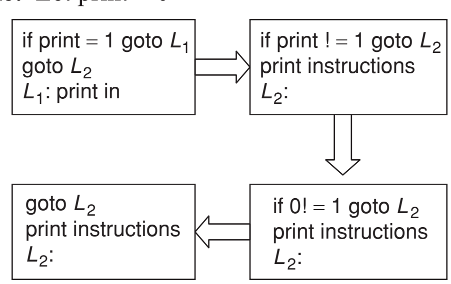
Second instruction can be deleted from both examples 3 and 4.

Example 5: Store R_0, x
Load x, R_0
Here load instruction can be deleted.

Eliminating Unreachable code
An unlabeled instruction immediately following and unconditional jump may be removed.

- May be produced due to debugging code introduced during development.
- May be due to updates in programs without considering the whole program segment.

Example: Let print = 0



In all of the above cases print instructions are unreachable.
∴ Print instructions can be eliminated.

Example: goto L_2
…
L_2:

Flow of control optimizations The unnecessary jumps can be eliminated.
Jumps like:
Jumps to jumps,
Jumps to conditional jumps,
Conditional jumps to jumps.

Example 1: we can replace the jump sequence

goto L_1

…

L_1: got L_2

By the sequence

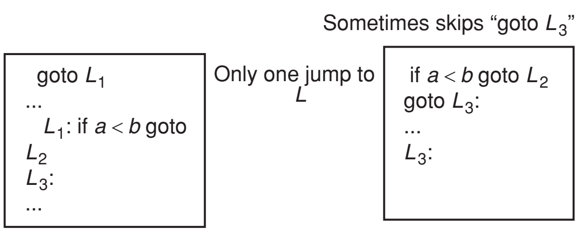
Got L_2

L_1: got $L_{2,}$

…

If there are no jumps to L_1 then it may be possible to eliminate the statement L_1: goto L_2.

Example 2:



Reduction in strength

- x^2 is cheaper to implement as $x * x$ than as a call to exponentiation routine.
- Replacement of multiplication by left shift.

Example: $x * 2^3 \Rightarrow x << 3$

- Replace division by right shift.

Example: $x >> 2$ (is $x/2^2$)

Use of machine Idioms

- Auto increment and auto decrement addressing modes can be used whenever possible.

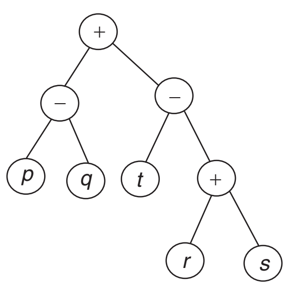
Example: replace add #1, R by INC R

Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices

1. Consider the following expression tree on a machine with bad store architecture in which memory can be accessed only through load and store instructions. The variables p, q, r, s and t are initially stored in memory. The binary operators used in this expression tree can be evaluated by the machine only when the operands are in registers. The instructions produce result only in a register if no intermediate results can be stored in memory, what is the minimum number of registers needed to evaluate this expression?



(A) 2 (B) 9
(C) 5 (D) 3

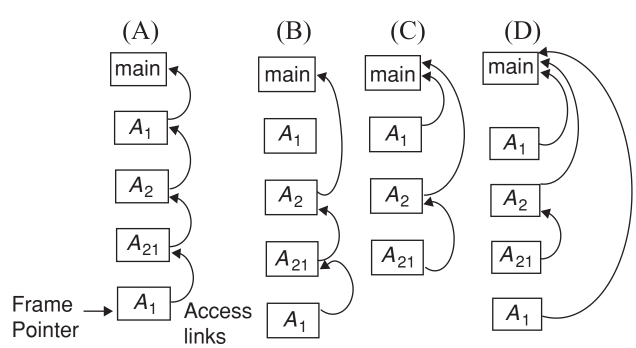
2. Consider the program given below with lexical scoping and nesting of procedures permitted.

Program main ( )

```
{
Var …
Procedure A1 ( )
{
Var …
call A2;
}
Procedure A2 ( )
{
Var..
Procedure A21 ( )
{
Var…
call A21 ( );
}
Call A1;
}
Call A1;
}
```

Consider the calling chain: main ( )→ A_1 ( ) → A_2 ( ) → A_{21} ( ) → A_1 ( ).

The correct set of activation records along with their access links is given by



3. Consider the program fragment:

```
sum = 0;
For (i = 1; i < = 20; i++)
sum = sum + a[i] +b[i];
```

How many instructions are there in the three-address code for this?

(A) 15 (B) 16
(C) 17 (D) 18

4. Suppose the instruction set of the processor has only two registers. The code optimization allowed is code motion. What is the minimum number of spills to memory in the complied code?

$c = a + b;$

$d = c*a;$

$e = c + a;$

$x = c*c;$

```
If (x > a)
{
y = a*a;
Else
{
d = d*d; e = e*e;
}
```

(A) 0 (B) 1
(C) 2 (D) 3

5. What is the minimum number of registers needed to compile the above problem's code segment without any spill to memory?

(A) 3 (B) 4
(C) 5 (D) 6

6. Convert the following expression into postfix notation:

$a = (-a + 2*b)/a$

(A) $aa - 2b$ *+a/= (B) $a - 2ba$ */+ =
(C) $a2b * a$/+ (D) $a2b - * a$/+

7. In the quadruple representation of the following program, how many temporaries are used?

int $a = 2$, $b = 8$, $c = 4$, d;

For ($j = 0$; $j< = 10$; j++)

$a = a * (j* (b/c));$

$d = a * (j* (b/c));$

(A) 4 (B) 7
(C) 8 (D) 10

8. Let $A = 2$, $B = 3$, $C = 4$ and $D = 5$, what is the final value of the prefix expression: + * $AB - CD$

(A) 5 (B) 10
(C) –10 (D) –5

9. Which of the following is a valid expression?

(A) $BC * D - +$ (B) $* ABC -$
(C) BBB ***– + (D) $-*/bc$

10. What is the final value of the postfix expression $B\ C\ D\ A\ D - + - +$ where $A = 2$, $B = 3$, $C = 4$, $D = 5$?

(A) 5 (B) 4
(C) 6 (D) 7

11. Consider the expression $x = (a + b)* -C/D$. In the quadruple representation of this expression in which instruction '/' operation is used?

(A) 3rd (B) 4th
(C) 5th (D) 8th

12. In the triple representation of $x = (a + b)*- c/d$, in which instruction $(a + b) * - c/d$ result will be assigned to x?

(A) 3rd (B) 4th
(C) 5th (D) 8th

13. Consider the three address code for the following program:

While ($A < C$ and $B > D$) do

If ($A = = 1$) then $C = C + 1$;

Else

While ($A < = D$) do

$A = A + 3$;

How many temporaries are used?

(A) 2 (B) 3
(C) 4 (D) 0

14. Code generation can be done by

(A) DAG (B) Labeled tree
(C) Both (A) and (B) (D) None of these

15. Live variables analysis is used as a technique for

(A) Code generation (B) Code optimization
(C) Type checking (D) Run time management

Practice Problems 2

Directions for questions 1 to 19: Select the correct alternative from the given choices

1. Match the correct code optimization technique to the corresponding code:

(i) $i = i * 1$ $j = 2 * i$	$\Rightarrow j = 2 * i$	(p) Reduction in strength
(ii) $A = B + C$ $D = 10 + B + C$	$\Rightarrow A = B + C$ $D = 10 + A$	(q) Machine Idioms
(iii) For $i = 1$ to 10 $A[i] = B + C$	$\Rightarrow$ for $i = 1$ to 10 $t = B + C$ $A[i] = t$;	(r) Common sub expression elimination.
(iv) $x = 2 * y \Rightarrow y << 2$;		(s) Code motion

(A) i – r, iii – s, iv – p, ii – q
(B) i – q, ii – r, iii – s, iv –p
(C) i – s, iii – p, iii – q, iv – r
(D) i – q, ii – p, iii – r, iv – s

2. What will be the optimized code for the following expression represented in DAG?

$a = q * -r + q * -r$

(A) $t_1 = -r$
$t_2 = q * t_1$
$t_3 = a * t_1$
$t_4 = t_2 + t_3$
$a = t_4$

(B) $t_1 = -r$
$t_2 = q * t_1$
$t_3 = t_2 + t_2$
$a = t_3$

(C) $t_1 = -r$
$t_2 = q$
$t_3 = t_1 * t_2$
$t_4 = t_3 + t_3$
$a = t_4$

(D) All of these

3. In static allocation, names are bound to storage at _______ time.

(A) Compile (B) Runtime
(C) Debugging (D) Both (A) and (B)

4. The actual parameters are evaluate d and their r-values are passed to the called procedure is known as

(A) call-by-reference
(B) call-by-name
(C) call-by-value
(D) copy-restore

5. If the expression $-(a + b) *(c + d) + (a + b + c)$ is translated into quadruple representation, then how many temporaries are required?

(A) 5 (B) 6
(C) 7 (D) 8

6. If the above expression is translated into triples representation, then how many instructions are there?

(A) 6 (B) 10
(C) 5 (D) 8

7. In the indirect triple representation for the expression $A = (E/F) * (C - D)$. The first pointer address refers to

(A) $C - D$
(B) E/F
(C) Both (A) and (B)
(D) $(E/F) * (C - D)$

8. For the given assembly language, what is the cost for it?

MOV b, a

ADD c, a

(A) 3 (B) 4
(C) 6 (D) 2

9. Consider the expression

((4 + 2 * 3 + 7) + 8 * 5). The polish postfix notation for this expression is

(A) 423* + 7 + 85*+ (B) 423* + 7 + 8 + 5*
(C) 42 + 37 + *85* + (D) 42 + 37 + 85** +

Common data for questions 10 to 15: Consider the following basic block, in which all variables are integers, and ** denotes exponentiation.

$a: = b + c$
$z: = a * * 2$
$x: = 0 * b$
$y: = b + c$
$w: = y * y$
$u: = x + 3$
$v: = u + w$

Assume that the only variables that are live at the exit of this block are v and z. In order, apply the following optimization to this basic block.

10. After applying algebraic simplification, how many instructions will be modified?

(A) 1 (B) 2
(C) 4 (D) 5

11. After applying common sub expression elimination to the above code. Which of the following are true?

(A) $a: = b + c$ (B) $y: = a$
(C) $z = a + a$ (D) None of these

12. Among the following instructions, which will be modified after applying copy propagation?

(A) $a: = b + c$ (B) $z: = a * a$
(C) $y: = a$ (D) $w: = y * y$

13. Which of the following is obtained after constant folding?

(A) $u: = 3$ (B) $v: = u + w$
(C) $x: = 0$ (D) Both (A) and (C)

14. In order to apply dead code elimination, what are the statements to be eliminated?

(A) $x = 0$
(B) $y = b + c$
(C) Both (A) and (B)
(D) None of these

15. How many instructions will be there after optimizing the above result further?

(A) 1 (B) 2
(C) 3 (D) 4

16. Consider the following program:

L_0: $e: = 0$
$b: = 1$
$d: = 2$
L_1: $a: = b + 2$
$c: = d + 5$
$e: = e + c$
f: $a*a$
If $f < c$ goto L_3
L_2: $e: = e + f$
goto L_4
L_3: $e: = e + 2$
L_4: $d: = d + 4$
$b: = b - 4$
If $b! = d$ goto 4
L_5:

How many blocks are there in the flow graph for the above code?

(A) 5
(B) 6
(C) 8
(D) 7

17. A basic block can be analyzed by

(A) Flow graph
(B) A graph with cycles
(C) DAG
(D) None of these

18. In call by value the actual parameters are evaluated. What type of values is passed to the called procedure?

(A) l-values
(B) r-values
(C) Text of actual parameters
(D) None of these

19. Which of the following is FALSE regarding a Block?

(A) The first statement is a leader.
(B) Any statement that is a target of conditional / unconditional goto is a leader.
(C) Immediately next statement of goto is a leader.
(D) The last statement is a leader.

Previous Years' Questions

1. The least number of temporary variables required to create a three-address code in static single assignment form for the expression $q + r/3 + s - t * 5 + u * v/w$ is ________ **[2015]**

2. Consider the intermediate code given below.

(1) $i = 1$
(2) $j = 1$
(3) $t_1 = 5 * i$
(4) $t_2 = t_1 + j$
(5) $t_3 = 4 * t_2$
(6) $t_4 = t_3$
(7) $a[t_4] = -1$
(8) $j = j + 1$
(9) if $j <= 5$ goto (3)
(10) $i = i + 1$
(11) if $i < 5$ goto (2)

The number of nodes and edges in the control-flow-graph constructed for the above code, respectively, are **[2015]**

(A) 5 and 7 (B) 6 and 7
(C) 5 and 5 (D) 7 and 8

3. Consider the following code segment. **[2016]**

$x = u - t;$
$y = x * v;$
$x = y + w;$
$y = t - z;$
$y = x * y;$

The minimum number of total variables required to convert the above code segment *to static single assignment form is* _____ .

4. What will be the output of the following pseudo-code when parameters are passed by reference and dynamic scoping is assumed? **[2016]**

$a = 3;$
void $n(x)$ { $x = x * a$; print (x);}
void $m(y)$ {$a = 1$; $a = y - a$; $n(a)$; print (a)}
void main( ) {$m(a)$;}

(A) 6,2 (B) 6,6
(C) 4,2 (D) 4,4

5. Consider the following intermediate program in three address code

$p = a - b$
$q = p * c$
$p = u * v$
$q = p + q$

Which one of the following corresponds to a *static single assignment* form of the above code? **[2017]**

(A) $p_1 = a - b$
$q_1 = p_1 * c$
$p_1 = u * v$
$q_1 = p_1 + q_1$

(B) $p_3 = a - b$
$q_4 = p_3 * c$
$p_4 = u * v$
$q_5 = p_4 + q_4$

(C) $p_1 = a - b$
$q_1 = p_2 * c$
$p_3 = u * v$
$q_2 = p_4 + q_3$

(D) $p_1 = a - b$
$q_1 = p * c$
$p_2 = u * v$
$q_2 = p + q$

Code Optimization

LEARNING OBJECTIVES

- *Code optimization basics*
- *Principle sources of optimization*
- *Loop invariant code motion*
- *Strength reduction on induction variables*
- *Loops in flow graphs*
- *Pre-header*
- *Global data flow analysis*
- *Definition and usage of variables*
- *Use-definition (u-d) chaining*
- *Data flow equations*

Code Optimization Basics

The process of improving the intermediate code and the target code in terms of both speed and the amount of memory required for execution is known as code optimization.

Compilers that apply code–improving transformations are called optimizing compilers.

Properties of the transformations of an optimizing compiler are

1. A transformation must preserve the meaning of programs.
2. It must speed up programs by a measurable amount.
3. A transformation must be worth the effort.

Places for improvements

1. Source Code:
   User can – profile a program
   – change an algorithm
   – transform loops
2. Intermediate code can be improved by improving
   – Loops
   – Procedure calls
   – Address calculations
3. Target code can be improved by
   – Using registers
   – Selecting instructions
   – Peephole transformations

Optimizing compiler organization

This applies

- Control flow analysis
- Data flow analysis
- Transformations

Issues in design of code optimization The issues in the design of code optimization are

1. Target machine characteristics
2. Target CPU architecture
3. Functional units

Target machine Optimization is done, according to the target machine characteristics. Altering the machine description parameters, one can optimize single piece of compiler code.

Target CPU architecture The issues to be considered for the optimization with respect to CPU architecture

1. Number of CPU registers
2. RISC Instruction set
3. CISC instruction set
4. Pipelining

Functional units Based on number of functional units, optimization is done. So that instructions can be executed simultaneously.

Principle Sources of Optimization

Some code improving transformation is Local transformations and some are Global transformations.

Local Transformations can be performed by looking only at a statement in a basic block. Otherwise it is global transformation.

Function Preserving Transformations

These transformations improve the program without changing the function it computes. Some of these transformations are

1. Common sub expression elimination
2. Copy propagation
3. Dead-code elimination
4. Loop optimization
   - Code motion
   - Induction variable elimination
   - Reduction in strength

Common sub expression elimination The process of identifying common sub expressions and eliminating their computation multiple times is known as common sub expression elimination.

Example: Consider the following program segment:

```
int sum_n, sum_n2, sum_n3;
int sum (int n)
{
Sum_n = ((n)*(n+1))/2;
sum_n2 = ((n)*(n+1)*(2n+1))/6;
sum_n3 = (((n)*(n+1))/2)*(((n)*(n+1))/2;
}
```

Three Address code for the above input is

(0) Proc-begin sum
(1) t_0: = $n + 1$
(2) t_1: = $n * t_0$
(3) t_2: = $t_1/2$
(4) sum_$n = t_2$
(5) t_3: = $n + 1$
(6) t_4: = $n *$ t_3
(7) t_5: $2 * n$
(8) t_6: = $t_5 + 1$
(9) t_7: = $t_4 * t_6$
(10) t_8: = $t_7/6$
(11) sum_n_2: = t_8
(12) t_9: = $n + 1$
(13) t_{10}: $n * t_9$
(14) t_{11}: $t_{10}/2$
(15) t_{12}: = $n + 1$
(16) t_{13}: = $n * t_{12}$
(17) t_{14}: = $t_{13}/2$
(18) t_{15}: = $t_{11} * t_{14}$
(19) sum_n_3: = t_{15}
(20) label L_o
(21) Proc end sum

The computations made in quadruples

(1) – (3), (12) – (14), (15) – (17) are essentially same. That is, $((n)*(n + 1))/2$ is computed.

It is the common sub expression.

This common sub expression is computed four times in the above example.

It is possible to optimize the code to have common sub expressions computed only once and then reuse the computed values further.

∴ Optimized intermediate code will be

(0) proc-begin sum
(1) t_0: = $n + 1$
(2) t_1: = $n * t_0$
(3) sultan: = $t_1/2$
(4) t_5: = $2 * n$
(5) t_6: = $t_5 + 1$
(6) t_7: = $t_1 * t_6$
(7) sum_n2: = $t_7/6$
(8) sum_n3: sum_n * sum_n
(9) proc-end sum

Constant folding The constant expressions in the input source are evaluated and replaced by the equivalent values at the time of compilation.

For example 10*3, 6 + 101 are constant expressions and they are replaced by 30, 107 respectively.

Example: Consider the following ‘*C*’ code:

```
int arr1 [10];
int main ( )
{
    arr1 [0] = 3;
    arr1 [1] = 4;
}
```

Unoptimized three address code equivalent to the above ‘*C*’ code is

(0) proc-begin main
(1) t_0: = 0*4
(2) t_1: = &arr1
(3) t_1 [t_0]: = 3
(4) t_2: = 1*4
(5) t_3: = &arr1
(6) t_3 [t_2]: = 4
(7) Label L_0
(8) Proc – end main

In the above code, 0*4 is a constant expression its value = 0. 1*4 is a constant expression, its value = 4.

∴ After applying constant folding, optimized code will be

(0) proc-begin main
(1) t_0: = 0
(2) t_1: = &arr1
(3) t_1 [t_0]: = 3
(4) t_2: = 4

(5) t_3: = &arr1
(6) t_3 [t_2]: = 4
(7) label L_0
(8) proc – end main

Copy propagation In copy propagation, if there is an expression $x = y$ then use the variable 'y' instead of 'x'. This propagated in the statements following $x = y$.

Example: In the previous example, there are two copy statements.

(1) $t_0 = 0$
(2) $t_2 = 4$

After applying copy propagation, the optimized code will be

(0) proc-begin main
(1) t_0: = 0
(2) t_1: = &arr1
(3) t_1 [0]: = 3
(4) t_2: = 4
(5) t_3: = &arr1
(6) t_3 [4]: = 4
(7) Label L_0
(8) proc-end main

In the three address code shown above, quadruples (1) and (4) are no longer used in any of the following statements.

∴ (1) and (4) can be eliminated.

Three address code after dead store elimination

(0) proc-begin main
(1) t_1: = &arr1
(2) t_1 [0]: = 3
(3) t_3: = &arr1
(4) t_3 [4]: = 4
(5) Label L_0
(6) proc-end main

In the above example, we are propagating constant values. It is also known as constant propagation.

Variable propagation Propagating another variable instead of the existing one is known as variable propagation.

Example: int func(int a, int b, int c)

```
{
    int d, e, f;
    d = a;
    If (a > 10)
    {
       e = d + b;
    }
    Else
    {
       e = d + c;
    }
    f = d*e;
    return (f);
}
```

Three address code (unoptimized):

(0) proc-begin func
$\boxed{(1)\ d := a}$
(2) if a >10 goto L_0
(3) goto L_1
(4) label : L_0
$\boxed{(5)\ e := d + b}$
(6) goto L_2
(7) label : L_1
$\boxed{(8)\ e := d + c}$
(9) label : L_2
$\boxed{(10)\ f := d * e}$
(11) return f
(12) goto L_3
(13) label : L_3
(14) proc-end func

Three address code after variable (copy) propagation:

(0) proc-begin func
(1) d: = a
(2) If a >10 goto .L_0
(3) goto L_1
(4) label: L_0
(5) e: = $a + b$
(6) goto L_2
(7) label: L_1
(8) e: = $a + c$
(9) label: L_2
(10) f: = a*e
(11) return f
(12) goto L_3
(13) label: L_3
(14) proc-end func

After dead store elimination:
In the above code (1) d: = a is no more used
∴ Eliminate the dead store d: = a

(0) proc-begin func
(1) If a > 10 goto L_0
(2) goto L_1
(3) label: L_0
(4) e: = $a + b$
(5) goto L_2
(6) label: L_1
(7) e: $a + c$
(8) label: L_2
(9) f: = a*e
(10) return f
(11) goto L_3
(12) label: L_3
(13) proc-end func

Dead code elimination Eliminating the code that never gets executed by the program is known as Dead code elimination. It reduces the memory required by the program

Example: Consider the following Unoptimized Intermediate code:

(0) proc-begin func
(1) debug: = 0
(2) If debug = = 1 goto L_0
(3) goto L_1
(4) label: L_0
(5) param c
(6) param b
(7) param a
(8) param lc1
(9) call printf 16
(10) retrieve to
(11) label: L_1
(12) $t_1 := a + b$
(13) $t_2 := t_1 + c$
(14) $v_1 := t_2$
(15) Return v_1
(16) goto L_2
(17) label: L_2
(18) proc-end func

In copy propagation, debug is replaced with 0, wherever debug is used after that assignment.

∴ Statement 2 will be changed as

If 0 = = 1 goto L_0

0 = = 1, always returns false.

∴ The control cannot flow to label: L_0

This makes the statements (4) through (10) as dead code. (2) Can also be removed as part of dead code elimination. (1) Cannot be eliminated, because 'debug' is a global variable. The optimized code after elimination of dead code is shown below.

(0) proc-begin func
(1) debug: = 0
(2) goto L_1
(3) label: L_1
(4) $t_1 := a + b$
(5) $t_2 := t_1 + c$
(6) $v_1 := t_2$
(7) return v_1
(8) goto L_2
(9) label: L_2
(10) proc-end func

Algebraic transformations We can use algebraic identities to optimize the code further. For example

Additive Identity: $a + 0 = a$

Multiplicative Identity: $a*1 = a$

Multiplication with 0: $a*0 = 0$

Example: Consider the following code fragment:

```
struct mystruct
{
int a [20];
int b;
} xyz;
int func(int i)
{
xyz.a[i] = 34;
}
```

The Unoptimized three address code:

(0) proc-begin func
(1) $t_0 := \&xyz$
$\boxed{(2)\ \ t_1 := 0}$
(3) $t_2 := i*4$
(4) $t_1 := t_2 + t_1$
(5) $t_0\,[t_1] = 34$
(6) label: L_0
(7) proc-end func

Optimized code after copy propagation and dead code elimination is shown below:

The statement $t_1 := 0$ is eliminated.

(0) proc-being func
(1) $t_0 =: = \&xyz$
(2) $t_2 := i*4$
$\boxed{(3)\ t_1 := t_2 + 0}$
(4) $t_0\,[t_1]: = 34$
(5) label: L_0
(6) proc-end func

After applying additive identity:

(0) proc-begin func
(1) $t_0 := \&xyz$
(2) $t_2 := i*4$
$\boxed{(3)\ t_1 := t_2}$
(4) $t_0\,[t_1]: = 34$
(5) label: L_0
(6) proc-end func

After copy propagation and dead store elimination:

(0) proc-begin func
(1) $t_0 := \&xyz$
(2) $t_2 := i*4$
(3) $t_0\,[t_2]: = 34$
(4) label: L_0
(5) proc-end func

Strength reduction transformation This transformation replaces expensive operators by equivalent cheaper ones on the target machine.

For example $y: = x*2$ is replaced by $y: = x + x$ as addition is less expensive than multiplication.

Similarly
Replace $y: = x*32$ by $y: = x << 5$
Replace $y: = x/8$ by $y: = x >> 3$

Loop optimization We can optimize loops by

(1) Loop invariant code motion transformation.
(2) Strength reduction on induction variable transformation.

Loop invariant code motion

The statements within a loop that compute value, which do not vary throughout the life of the loop are called loop invariant statements.

Consider the following program fragment:

```
int a [100];
int func(int x, int y)
{
int i;
int n1, n2;
i = 0;
n1 = x*y;
n2 = x - y;
while (a[i] > (n1*n2))
i = i + 1;
return(i);
}
```

The Three Address code for above program is

(0) proc-begin func
(1) $i := 0$
(2) $n_1 := x*y$
(3) $n_2 := x - y$
(4) label : L_0
(5) $t_2 := i*4$
$\boxed{(6)\ t_3 := \&arr}$
(7) $t_4 := t_3[t_2]$
$\boxed{(8)\ t_5 := n_1 * n_2}$
(9) if $t_4 > t_5$ goto L_1
(10) goto L_2
(11) label : L_1
(12) $i := i + 1$
(13) goto L_0
(14) label : L_2
(15) return i
(16) goto L_3
(17) label : L_3
(18) proc-end func

In the above code statements (6) and (8) are invariant.

After loop invariant code motion transformation the code will be

(0) proc-begin func
(1) $i := 0$
(2) $n_1 := x*y$
(3) $n_2 := x\text{-}y$
(4) $t_3 := \&arr$
(5) $t_5 : n_1*n_2$
(6) label : L_0
(7) $t_2 := i*4$
(8) $t_4 := t_3[t_2]$
(9) if $t_4 > t_5$ goto L_1
(10) goto L_2
(11) label : L_1
(12) $i := i + 1$
(13) goto L_0
(14) label : L_2
(15) return i
(16) goto L_3
(17) label : L_3
(18) proc-end func

Strength reduction on induction variables

Induction variable: A variable that changes by a fixed quantity on each of the iterations of a loop is an induction variable.

Example: Consider the following code fragment:

```
int i;
int a[20];
int func( )
{
    while(i<20)
    {
    a[i] = 10;
    i = i + 1;
    }
}
```

The three-address code will be

(0) proc-begin func
(1) label : L_0
(2) if $i < 20$ goto L_1
(3) goto L_2
(4) label : L_1
(5) $t_0 := i*4$
(6) $t_1 := \&a$
(7) $t_1[t_0] := 10$
(8) $i := i + 1$
(9) goto L_0
(10) label : L_2
(11) label : L_3
(12) proc-end func

After reduction of strength the code will be
Here (5) $t_0 = i*4$ is moved out of the loop and (8) is followed by $t_0 = t_0 + 4$.

(0) proc-begin func
(0a) $t_0 := i*4$
(1) label : L_0
(2) if $i < 20$ goto L_1
(3) goto L_2
(4) label:L_1
(5)
(6) $t_1 := \&a$
(7) $t_1[t_0] := 10$
(8) $i := i + 1$
(8a) $t_0 := t_0 + 4$
(9) goto L_0
(10) label : L_2
(11) label : L_3
(12) proc-end func

Loops in Flow Graphs

Loops in the code are detected during the data flow analysis by using the concept called 'dominators' in the flow graph.

Dominators

A node d of a flow graph dominates node n, if every path from the initial node to 'n' goes through 'd'.

It is represented as d dom n.

Notes:

1. Each and every node dominates itself.
2. Entry of the loop dominates all nodes in the loop.

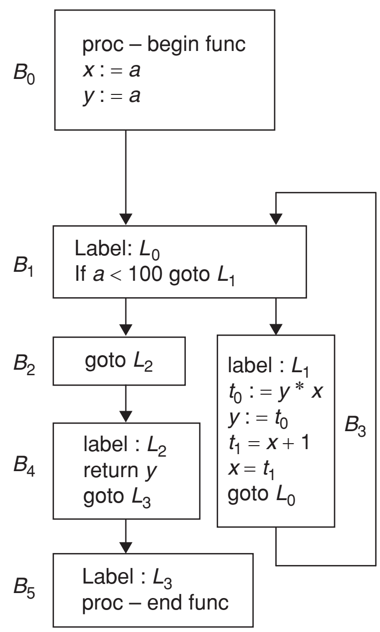
Example: Consider the following code fragment:

```
int func(int a)
{
int x, y;
x = a;
y = a;
While (a < 100)
{
y = y*x;
x = x+1;
}
return(y);
}
```

The Three Address code after local optimization will be

(0) proc-begin func
(1) $x := a$
(2) $y := a$
(3) label: L_0
(4) if $a < 100$ goto L_1
(5) goto L_2
(6) label: L_1
(7) $t_0 := y*x$
(8) $y := t_0$
(9) $t_1 := x + 1$
(10) $x := t_1$
(11) goto L_0
(12) label: L_2
(13) return y
(14) goto L_3
(15) label: L_3
(16) proc-end func

The Flow Graph for above code will be:



To reach B_2, it must pass through B_1

$\therefore$ B_1 dominates B_2. Also B_0 dominates B_2.

dominators $[B_1] = \{B_0, B1\}$ (or) dominators $[1] = \{0, 1\}$

The dominators for each of the nodes in the flow graph are

dominators [0] = {0}
dominators [1] = {0, 1}
dominators [2] = {0, 1, 2}
dominators [3] = {0, 1, 3}
dominators [4] = {0, 1, 2, 4}
dominators [5] = {0, 1, 2, 4, 5}

Edge

An edge in a flow graph represents a possible flow of control.

In the flow graph, B_0 to B_1 edge is represented as $0 \rightarrow 1$.

Head and tail: In the edge $a \rightarrow b$, the node b is called head and the node a is called as tail.

Back edges: There are some edges in which dominators [tail] contains the head.

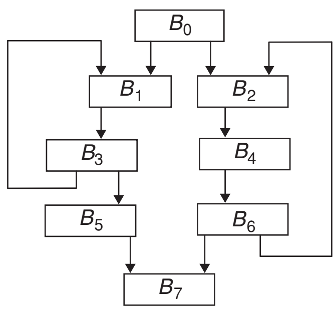
The presence of a back edge indicates the existence of a loop in a flow graph.

In the previous graph, $3 \rightarrow 1$ is a back edge.

Consider the following table:

Edge	Head	Tail	Dominators [head]	Dominators [tail]
$0 \rightarrow 1$	1	0	{0, 1}	{0}
$1 \rightarrow 2$	2	1	{0, 1, 2}	{0, 1}
$1 \rightarrow 3$	3	1	{0, 1, 3}	{0, 1}
$3 \rightarrow 1$	1	3	{0, 1}	{0, 1, 3}
$2 \rightarrow 4$	4	2	{0, 1, 2, 4}	{0, 1, 2}
$4 \rightarrow 5$	5	4	{0, 1, 2, 4, 5}	{0, 1, 2, 4}

Example: Consider below flow graph:



The dominators of each node are

dominators [0] = {0}
dominators [1] = {0, 1}
dominators [2] = {0, 2}
dominators [3] = {0, 1, 3}
dominators [4] = {0, 2, 4}
dominators [5] = {0, 1, 3, 5}
dominators [6] = {0, 2, 4, 6}
dominators [7] = {0, 7}

Edge	Head	Tail	Dominators [head]	Dominators [tail]
$0 \rightarrow 1$	1	0	{0, 1}	{0}
$0 \rightarrow 2$	2	0	{0, 2}	{0}
$1 \rightarrow 3$	3	1	{0, 1, 3}	{0, 1}
$3 \rightarrow 1$	1	3	{0, 1}	{0, 1, 3}
$3 \rightarrow 5$	5	3	{0, 1, 3, 5}	{0, 1, 3} Backedge
$5 \rightarrow 7$	7	5	{0, 7}	{0, 1, 3, 5}
$2 \rightarrow 4$	4	2	{0, 2, 4}	{0, 2}
$6 \rightarrow 2$	2	6	{0, 2}	{0, 2, 4, 6} Backedge
$4 \rightarrow 6$	6	4	{0, 2, 4, 6}	{0, 2, 4}
$6 \rightarrow 7$	7	6	{0, 7}	{0, 2, 4, 6}

Here $\{B_6, B_2, B_4\}$ form a loop (L_1), $\{B_3, B_1\}$ form another loop (L_2)

In a loop, the entry of the loop dominates all nodes in the loop.

Header of the loop The entry of the loop is also called as the header of the loop.

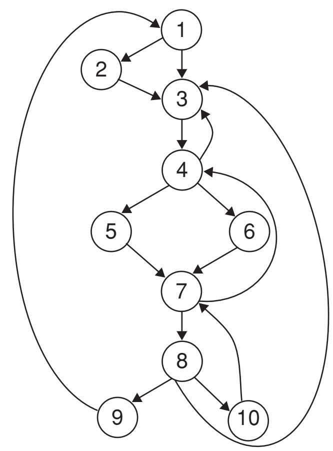
Loop exit block In loop L_1 can be exited from the basic block B_6. It is called loop exit block. The block B_3 is the loop exit block for the loop L_2. It is possible to have multiple exit blocks in a loop.

Dominator tree

A tree, which represents dominate information in the form of tree is a dominator tree. In this,

- The initial node is the root.
- Each node d dominates only its descendents in the tree.

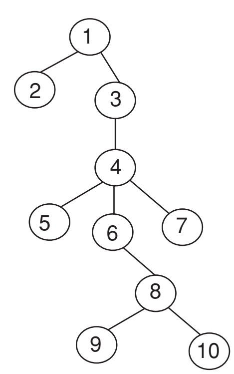
Consider the flow graph



The dominators of each node are

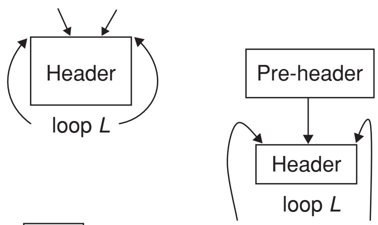
dominators [1] = {1}
dominators [2] = {1, 2}
dominators [3] = {1, 3}
dominators [4] = {1, 3, 4}
dominators [5] = {1, 3, 4, 5}
dominators [6] = {1, 3, 4, 6}
dominators [7] = {1, 3, 4, 7}
dominators [8] = {1, 3, 4, 7, 8}
dominators [9] = {1, 3, 4, 7, 8, 9}
dominators [10] = {1, 3, 4, 7, 8, 10}

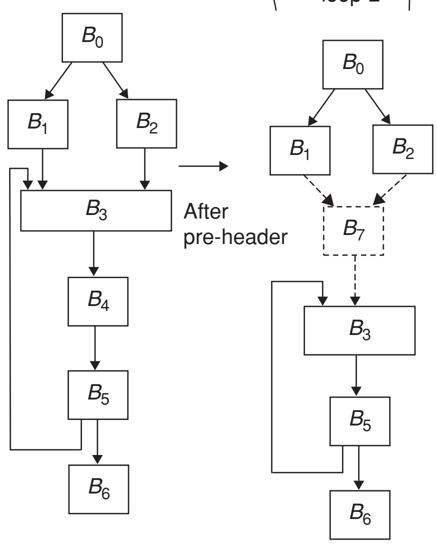
The dominator tree will be:



Pre-header

A pre-header is a basic block introduced during the loop optimization to hold the statements that are moved from within the loop. It is a predecessor to the header block.





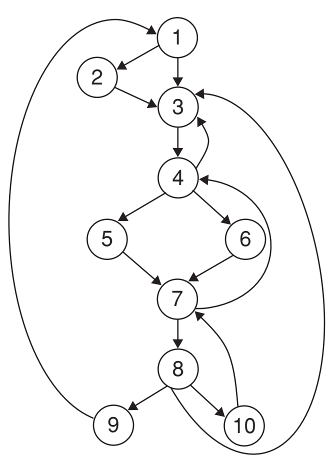
Reducible Flow Graphs

A flow graph G is reducible if and only if we can partition the edges into two disjoint groups:

(1) Forward edges
(2) Backward edges with the following properties.

(i) The forward edges form an acyclic graph in which every node can be reached from the initial node of G.
(ii) The back edges consist only of edges whose heads dominates their tails.

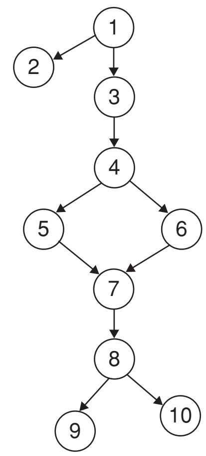
Example: Consider previous flow graph



In the above flow graph, there are five back edges

$$4 \to 3,\ 7 \to 4,\ 8 \to 3,\ 9 \to 1 \text{ and } 10 \to 7$$

Remove all backedges.
The remaining edges must be the forward edges.
The remaining graph is acyclic.



∴ It is reducible.

Global Dataflow Analysis

Point: A point is a place of reference that can be found at

1. Before the first statement in a basic block.
2. After the last statement in a basic block.
3. In between two adjacent statements within a basic block.

Example 1:

$a' = 10$
$b' = 20$
$c' = a * b$ $\quad B_1$

Here, In B_1 there are 4 points

Example 2:

B_1

• $P_1 - B_1$
proc-begin func
• $P_2 - B_1$
$v_3 = v_1 + v_2$
• $P_3 - B_1$
if $c > 100$ goto L_0
• $P_4 - B_1$

There is 4 point in the basic block B_1, given by $P_1 - B_1$, $P_2 - B_1$, $P_3 - B_1$ and $P_4 - B_1$.

Path: A path is a sequence of points in which the control can flow.

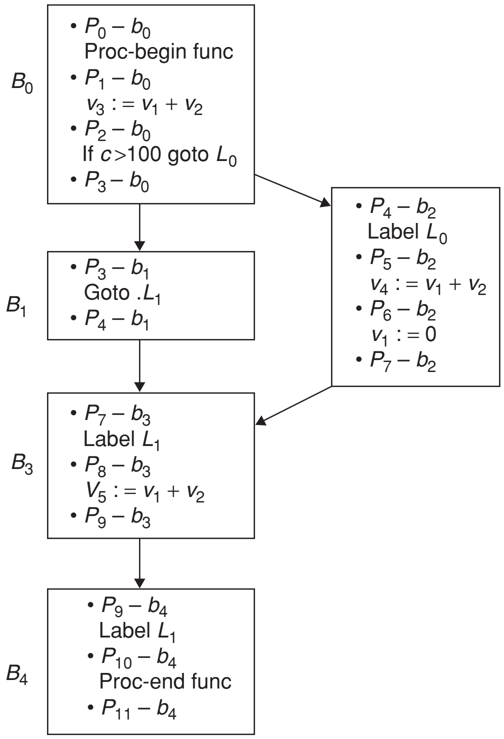
A path from P_1 to P_n is a sequence of points $P_1, P_2, \ldots, P_n$ such that for each i between 1 and n-1, either

(a) P_i is the point immediately preceding a statement and P_{i+1} is the point immediately following that statement in the same block.

(OR)

(b) P_i is the end of some block and P_{i+1} is the beginning of a successor block.

Example:



Path is between the points $P_0 - b_0$ and $P_6 - b_2$:

The sequence of points $P_0 - b_0$, $P_1 - b_0$, $P_2 - b_0$, $P_3 - b_0$, $P_4 - b_2$, $P_5 - b_2$ and $P_6 - b_2$.

Path between $P_3 - b_1$ and $P_6 - b_2$: There is no sequence of points.

Path between $P_0 - b_0$ and $P_7 - b_3$: There are two paths.

(1) Path 1 consists of the sequence of points, $P_0 - b_0$, $P_1 - b_0$, $P_2 - b_0$, $P_3 - b_0$, $P_3 - b_0$, $P_4 - b_1$ and $P_7 - b_3$.

(2) Path 2 consists of the sequence of points $P_0 - b_0$, $P_1 - b_0$, $P_2 - b_0$, $P_3 - b_0$, $P_4 - b_2$, $P_5 - b_2$, $P_6 - b_2$, $P_7 - b_2$ and $P_7 - b_3$

Definition and Usage of Variables

Definitions

It is either an assignment to the variable or reading of a value for the variable.

Use

Use of identifier x means any occurrence of x as an operand.

Example: Consider the statement

$$x = y + z;$$

In this statement some value is assigned to x. It defines x and used y and z values.

Global Data-Flow-Analysis

Data Flow Analysis (DFA) is a technique for gathering information about the possible set of values calculated at various points in a program.

- An example of a data-flow analysis is reaching definitions.
- A single way to perform data-flow analysis of program is to setup data flow equations for each node of the control flow graph.

Use definition (U-d) chaining

The use of a value is any point where that variable or constant is used in the right hand side of an assignment or is evaluating an expression.

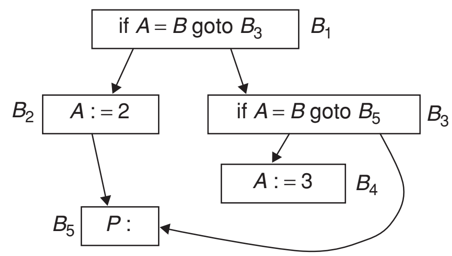
The definition of a value occurs implicitly at the beginning of the whole program for a variable.

A point is defined either prior to or immediately after a statement.

Reaching definitions

A definition of a variable A reaches a point P if there is a path in the flow graph from that definition to P, such that no other definitions of A appear on the path.

Example:



The definition A: = 3 can reach point p in B_5.

To determine the definitions that can reach a given program first assign distinct numbers to each definition, since it is associated with a unique quadruple.

- For each simple variable A, make a list of all definitions of A anywhere in the program.
- Compute two sets for each basic block B.

Gen [B] is the set of generated definitions within block B and that reach the end of the block.

1. Kill [B], which is the set of definitions outside of B that define identifiers that also have definitions within B.
2. IN [B], which are all definitions reaching the point just before B's first statement.

Once this is known, the definitions reaching any use of A within B are found by:

Let u be the statement being examined, which uses A.

1. If there are definitions of A within B before u, the last is the only one reaching u.
2. If there is no definition of A within B prior to u, those reaching u are in IN [B].

Data Flow Equations

1. For all blocks B,

$$\text{OUT }[B] = (\text{IN }[B] - \text{KILL }[B]) \text{ U GEN }[B]$$

A definition d, reaches the end of B if

(a) $d \in$ IN [B] and is not killed by B.
(or)
(b) d is generated in B and is not subsequently redefined here.

2. IN [B] = U OUT [P]
$\forall P$ preceding B
A definition reaches the beginning of B iff it reaches the end of one of its predecessors.

Computing U-d Chains

If a use of variable 'a' is preceded in its block by a definition of 'a', this is the only one reaching it.

If no such definition precedes its use, all definitions of 'a' in IN [B] are on its chain.

Uses of U-d Chains

1. If the only definition of 'a' reaching this statement involves a constant, we can substitute that constant for 'a'.
2. If no definitions of 'a' reaches this point, a warning can be given.
3. If a definition reaches nowhere, it can be eliminated. This is part of dead code elimination.

Exercises

Practice Problems I

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. Replacing the expression 2 * 3.14 by 6.28 is
(A) Constant folding
(B) Induction variable
(C) Strength reduction
(D) Code reduction

2. The expression (a*b)*c op … where 'op' is one of '+', '*' and '↑' (exponentiation) can be evaluated on CPU with a single register without storing the value of (a*b) if
(A) 'op' is '+' or '*'
(B) 'op' is '↑' or '+'
(C) 'op' is '↑' or '*'
(D) not possible to evaluate without storing

3. Machine independent code optimization can be applied to
(A) Source code
(B) Intermediate representation
(C) Runtime output
(D) Object code

4. In block B if S occurs in B and there is no subsequent assignment to y within B, then the copy statement $S : x = y$ is
(A) Generated (B) Killed
(C) Blocked (D) Dead

5. If E was previously computed and the value of variable in E have not changed since previous computation, then an occurrence of an expression E is
(A) Copy propagation
(B) Common sub expression
(C) Dead code
(D) Constant folding

6. In block B, if x or y is assigned there and s is not in B, then $s : x = y$ is
(A) Generated (B) Killed
(C) Blocked (D) Dead

7. Given the following code
$A = x + y$;
$B = x + y$;
Then the corresponding optimized code as
_____
_____
$C = x + y$;
_____
$A = C$;
_____
$B = C$;
When will be optimized code pose a problem?
(A) When C is undefined.
(B) When memory is consideration.
(C) C may not remain same after some statements.
(D) Both (A) and (C).

8. Can the loop invariant $X = A - B$ from the following code be moved out?
For i = 1 to 10
```
{
A = B * C;
X = A - B;
}
```
(A) No
(B) Yes
(C) $X = A - B$ is not invariant
(D) Data insufficient

9. If every path from the initial node goes through a particular node, then that node is said to be a
(A) Header (B) Dominator
(C) Parent (D) Descendant

Common data for questions 10 and 11: Consider the following statements of a block:

$a: = b + c$
$b: = a - d$
$c: = b + c$
$d: = a - d$

10. The above basic block contains, the value of b in 3rd statement is
(A) Same as b in 1st statement
(B) Different from b in 1st statement
(C) 0
(D) 1

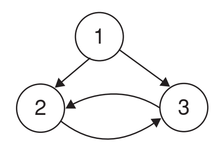
11. The above basic block contains
(A) Two common sub expression
(B) Only one common sub expression
(C) Dead code
(D) Temporary variable

12. Find the induction variable from the following code:
$A = -0.2;$
$B = A + 5.0;$
(A) A
(B) B
(C) Both A and B are induction variables
(D) No induction variables

13. The analysis that cannot be implemented by forward operating data flow equations mechanism is
(A) Interprocedural
(B) Procedural
(C) Live variable analysis
(D) Data

14. Which of the following consist of a definition, of a variable and all the uses, U, reachable from that definition without any other intervening definitions?
(A) Ud-chaining (B) Du-chaining
(C) Spanning (D) Searching

15. Consider the graph



The graph is
(A) Reducible graph
(B) Non-reducible graph
(C) Data insufficient
(D) None of these

Practice Problems 2

Directions for questions 1 to 15: Select the correct alternative from the given choices.

1. In labeling algorithm, let n is a binary node and its children have L_1 and L_2, if $L_1 = L_2$ then LABEL (n):
(A) $L_1 - 1$ (B) $L_2 + 1$
(C) $L_1 + L_1$ (D) $L_1 + 1$

2. The input for the code generator is a:
(A) Tree at lexical level
(B) Tree at semantic level
(C) Sequence of assembly language instructions
(D) Sequence of machine idioms

3. In labeling algorithm, let n is a binary node and its children have i_1 and i_2, LABEL (n) if $i_1 \neq i_2$ is
(A) Max (i_1, i_2)
(B) $i_2 + 1$
(C) $i_2 - 1$
(D) $i_2 - i_1$

4. The following tries to keep frequently used value in a fixed register throughout a loop is:
(A) Usage counts
(B) Global register allocation
(C) Conditional statement
(D) Pointer assignment

5. Substitute y for x for copy statement $s : x = y$ if the following condition is met
(A) Statements s may be the only definition of x reaching u
(B) x is dead
(C) y is dead
(D) x and y are aliases

6. Consider the following code

```
for (i=0; i<m; i++)
{
for (j=0; j<m; j ++)
If (i%2)
{
a = a + (14*j+5*i);
b = b + (9 + 4*j);
}
}
```

Which of the following is false?
(A) There is a scope of common reduction in this code
(B) There is a scope of strength reduction in this code.
(C) There is scope of dead code elimination in this code
(D) Both (A) and (C)

7. S_1: In dominance tree, the initial node is the root.
S_2: Each node d dominates only its ancestors in the tree.
S_3: if $d \neq n$ and d dom n then d dom m.

Which of the statements is/are true?
(A) S_1, S_2 are true
(B) S_1, S_2 and S_3 are true

(C) Only S_3 is true
(D) Only S_1 is true

8. The specific task storage manager performs:
(A) Allocation/Deallocation of storage to programs
(B) Protection of storage area allocated to a program from illegal access by other programs in the system
(C) The status of each program
(D) Both (A) and (B)

9. Concept which can be used to identify loops is:
(A) Dominators
(B) Reducible graphs
(C) Depth first ordering
(D) All of these

10. A point cannot be found:
(A) Between two adjacent statements
(B) Before the first statement
(C) After the last statement
(D) Between any two statements

11. In the statement, $x = y*10 + z$; which is/are defined?
(A) x (B) y
(C) z (D) Both (B) and (C)

12. Consider the following program:

```
void main ( )
{
    int x, y;
    x = 3; y = 7;
    --------
    --------
    if (x<y)
    {
    int x;
    {
    int y;
    y = 9;
    ------
    x = 2*y;
    }
    -------
    -------
    x = x + y;
    printf ("%d", x);
    }
    ------
    printf ("%d", x);
}
```

The output is
(A) 3 – 25 (B) 25 – 3
(C) 3 – 3 (D) 25 – 25

13. The evaluation strategy which delays the evaluation of an expression until its value is needed and which avoids repeated evaluations is:
(A) Early evaluation (B) Late evaluation
(C) Lazy evaluation (D) Critical evaluation

14. If two or more expressions denote same memory address, then the expressions are:
(A) Aliases (B) Definitions
(C) Superiors (D) Inferiors

15. Operations that can be removed completely are called:
(A) Strength reduction
(B) Null sequences
(C) Constant folding
(D) None of these

Previous Years' Questions

1. In a compiler, keywords of a language are recognized during: **[2011]**
(A) parsing of the program
(B) the code generation
(C) the lexical analysis of the program
(D) dataflow analysis

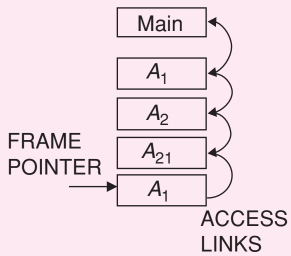
2. Consider the program given below, in a block structured pseudo-language with lexical scoping and nesting of procedures permitted. **[2012]**

Program main;
Var …
Procedure A_1;
Var …
Call A_2;
End A_1
Procedure A_2;
Var …
Procedure A_{21};
Var …
Call A_1;
End A_{21}
Call A_{21};
End A_2
Call A_1;
End main

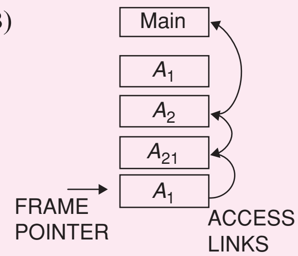
Consider the calling chain: Main $\rightarrow A_1 \rightarrow A_2 \rightarrow A_{21} \rightarrow A_1$

The correct set of activation records along with their access links is given by:

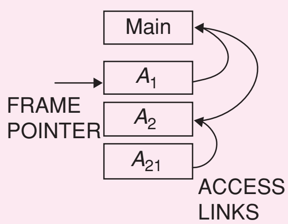
(A)



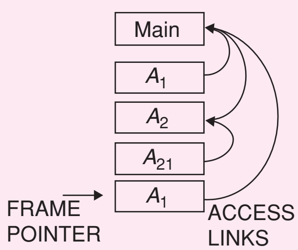
(B)



(C)



(D)



Common data for questions 3 and 4: The following code segment is executed on a processor which allows only register operands in its instructions. Each instruction can have atmost two source operands and one destination operand. Assume that all variables are dead after this code segment.

```
c = a + b;
d = c * a;
e = c + a;
x = c * c;
If (x > a) {
   y = a * a;
}
Else {
      d = d * d;
      e = e * e;
}
```

3. What is the minimum number of registers needed in the instruction set architecture of the processor to compile this code segment without any spill to memory? Do not apply any optimization other than optimizing register allocation. **[2013]**

(A) 3 (B) 4
(C) 5 (D) 6

4. Suppose the instruction set architecture of the processor has only two registers. The only allowed compiler optimization is code motion, which moves statements from one place to another while preserving correctness. What is the minimum number of spills to memory in the compiled code? **[2013]**

(A) 0 (B) 1
(C) 2 (D) 3

5. Which one of the following is NOT performed during compilation? **[2014]**

(A) Dynamic memory allocation
(B) Type checking
(C) Symbol table management
(D) Inline expansion

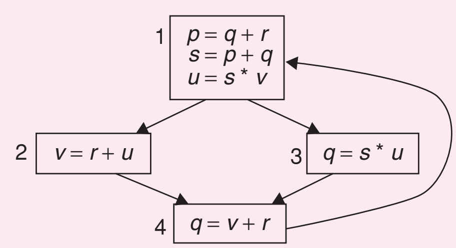
6. Which of the following statements are CORRECT? **[2014]**

(i) Static allocation of all data areas by a compiler makes it impossible to implement recursion.
(ii) Automatic garbage collection is essential to implement recursion.
(iii) Dynamic allocation of activation records is essential to implement recursion.
(iv) Both heap and stack are essential to implement recursion.

(A) (i) and (ii) only (B) (ii) and (iii) only
(C) (iii) and (iv) only (D) (i) and (iii) only

7. A variable x is said to be live at a statement S_i in a program if the following three conditions hold simultaneously: **[2015]**

1. There exists a statement S_j that uses x
2. There is a path from S_i to S_j in the flow graph corresponding to the program.
3. The path has no intervening assignment to x including at S_i and S_j.



The variables which are live both at the statement in basic block 2 and at the statement in basic block 3 of the above control flow graph are

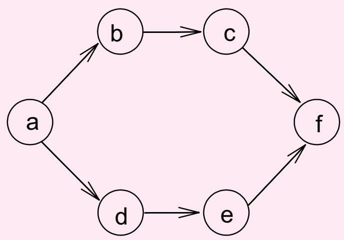
(A) p, s, u (B) r, s, u
(C) r, u (D) q, v

8. Match the following **[2015]**

P. Lexical analysis	1. Graph coloring
Q. Parsing	2. DFA minimization
R. Register allocation	3. Post-order traversal
S. Expression evaluation	4. Production tree

(A) P–2, Q–3, R–1, S–4 (B) P–2, Q–1, R–4, S–3
(C) P–2, Q–4, R–1, S–3 (D) P–2, Q–3, R–4, S–1

9. Consider the following directed graph:



The number of different topological orderings of the vertices of the graph is _______ . **[2016]**

10. Consider the following grammar:

stmt –> **if** expr **then** expr **else** expr; stmt | Ò
expr –> term **relop** term | term
term –> id | number
id –> **a** | **b** | **c**
number –> **[0 – 9]**

where **relop** is a relational operator (e.g., <, >,…), Ò refers to the empty statement, and **if, then, else** are terminals.

Consider a program *P* following the above grammar containing ten **if** terminals. The number of control flow paths in *P* is__________. For example, the program

if e_1 **then** e_2 **else** e_3

has 2 control flow paths, $e_1 \rightarrow e_2$ and $e_1 \rightarrow e_3$. **[2017]**

11. Consider the expression $(a—1) * (((b + c)/3) + d))$. Let X be the minimum number of registers required by an *optimal* code generation (without any register spill) algorithm for a load/store architecture, in which *(i) only load and store instruction can have memory operands and (ii) arithmetic instructions can have only register or immediate operands*. The value of X is _____. **[2017]**

12. Match the following according to input (from the left column) to the compiler phase (in the right column) that processes it: **[2017]**

(P) Syntax tree	(i) Code generator
(Q) Character stream	(ii) Syntax analyzer
(R) Intermediate representation	(iii) Semantic analyzer
(S) Token stream	(iv) Lexical analyzer

(A) P → (ii), Q → (iii), R → (iv), S → (i)
(B) P → (ii), Q → (i), R → (iii), S → (iv)
(C) P → (iii), Q → (iv), R → (i), S → (ii)
(B) P → (i), Q → (iv), R → (ii), S → (iii)

Test

Compiler Design

Time: 45 min.

Directions for questions 1 to 30: Select the correct alternative from the given choices.

1. The most powerful parsing method is
(A) LALR (B) LR
(C) CLR (D) LL (1)

2. In which phase 'type checking' is done?
(A) Lexical analysis
(B) Code optimization
(C) Syntax analysis
(D) Semantic analysis

3. A shift reduces parser carries out the actions specified within braces immediately after reducing the corresponding rule of grammar, as below:
$S \to aaD$ {Print "1"}.
$S \to b$ {Print "2"}
$D \to Sc$ {Print "3"}
What is the translation of 'aaaabcc' using the syntax directed translation scheme described by the above rules?
(A) 33211 (B) 11233
(C) 11231 (D) 23131

4. $E \to TE'$
$E' \to +TE'/\in$
$T \to FT'$
$T' \to *FT'/\in$
$F \to (E)/id$
From above grammar, FOLLOW (E) is
(A) {), $} (B) {$, *)}
(C) {(, id} (D) {+,), $}

5. To eliminate backtracking, which one is used?
(A) Left Recursion
(B) Left Factoring
(C) Right Recursion
(D) Right Factoring

6. Consider the grammar
$T \to (T) \mid \in$
Let the number of states in SLR (1), LR (1) and LALR (1) parsers for the grammar be n_1, n_2 and n_3 respectively. Which relationship holds well?
(A) $n_1 = n_2 = n_3$
(B) $n_1 \geq n_3 \geq n_2$
(C) $n_1 = n_3 < n_2$
(D) $n_1 < n_2 < n_3$

7. If w is a string of terminals and A, B are two non-terminals then which of the following are left-linear grammars?
(A) $A \to wB/w$
(B) $A \to Bw/w$
(C) $A \to wB$
(D) None of the above

8. The grammar $E \to E * E/E + E/a$, is
(A) Ambiguous
(B) Unambiguous
(C) Will not depend on the given sentence
(D) None of these

9. Shift-reduce parsers are
(A) Bottom up parsers
(B) Top down parsers
(C) Both (A) and (B)
(D) None of these

10. Consider the following grammars:
I. $E \to TE'$
$E' \to +TE'/\in$
$T \to FT'$
$T' \to *FT'/\in$
$F \to (E)/id$
II. $S \to iCtSS' \mid a$
$S' \to eS \mid \in$
$C \to b$
Which of the following is true?
(A) II is LL (1) (B) I is LL (1)
(C) Both (A) and (B) (D) None of these

11. Consider the following grammar:
$S \to iCtSS'/a$
$S' \to eS/\in$
$C \to b$
First (S') is
(A) $\{i, a\}$ (B) $\{\$, e\}$
(C) $\{e, \in\}$ (D) $\{b\}$

12. From the above grammar Follow(S) is.
(A) $\{\$, e\}$ (B) $\{\$\}$
(C) $\{e\}$ (D) $\{\$,), e\}$

13. Find the LEADING (S) from the following grammar:
$S \to a \mid \wedge \mid (T)$
$T \to T, S / S$
(A) $\{a, \wedge, (\,\}$ (B) $\{, a,)\}$
(C) $\{, a, (\,\}$ (D) $\{, a, \wedge,)\}$

14. From above grammar find the TRAILING (T).
(A) $\{a,)\}$ (B) $\{a, \wedge,)\}$
(C) $\{),\}$ (D) $\{, a,)\}$

15. Which of the following remarks logically follows?
(A) FIRST $(\in) = \{\in\}$.
(B) If FOLLOW (A) contains $, then A may or may not be the start symbol.
(C) If $A \to w$, is a production in the given grammar G, then $FIRST_k$ (A) contains $FIRST_k$ (w).
(D) All of the above

16. Consider the following grammar:
$S \rightarrow AB$
$B \rightarrow ab$
$A \rightarrow aa$
$A \rightarrow a$
$B \rightarrow b.$
The grammar is
(A) Ambiguous
(B) Unambiguous
(C) Can't predictable
(D) None of these

17. If a handle has been found but there is no production with this handle as a right side, then we discover
(A) Logical error
(B) Runtime error
(C) Syntactic error
(D) All of the above

18. The function of syntax phase is
(A) To build a literal table
(B) To build an uniform symbol table
(C) To parse the tokens produced by lexical analyzer
(D) None of these

19. Which of the following are cousins of compilers?
(A) Pre-processor and Assembler
(B) Assembler and LEX
(C) Pre-processor and YACC
(D) LEX and YACC.

20. Error is detected in predictive parsing when ____ hold(s).
(i) 'a' on top of stack and next input symbol is 'b'.
(ii) When 'a' is on top of stack, 'a' is next input symbol and parsing table entry $M[A, a]$ is empty.
(A) Neither (i) nor (ii)
(B) Both (i) and (ii)
(C) only (i)
(D) only (ii)

21. Which one indicates abstract syntax tree (AST) of "$a * b + c$" with following grammar:
$E \rightarrow E * T/T$
$T \rightarrow T + F/F$
$F \rightarrow id$

(A) 
(B) 
(C) 
(D) 
22. The parse tree is constructed and then it is traversed and the semantic rules are evaluated in a particular order by a
(A) Recursive evaluator
(B) Bottom up translation
(C) Top down translation
(D) Phase tree method

23. The following grammar indicates
$S \rightarrow a\ \alpha\ b | b\ \alpha\ c | a\ b$
$S \rightarrow \alpha\ S\ | b$
$S \rightarrow \alpha\ b\ b/a\ b$
$S \rightarrow \alpha\ b\ d\ b/b$
(A) LR (0) grammar
(B) SLR grammar
(C) Regular grammar
(D) None of these

24. If the attributes of the child depends on the attributes of the parent node then it is ____ attribute.
(A) Inherited
(B) Directed
(C) Synthesised
(D) TAC

25. The semantic rule is evaluated and the intermediate code is generated when the production is expanded in ____
(A) Parse tree method
(B) Bottom up translation
(C) Top down translation
(D) Recursive evaluator model

26. Consider the grammar shown below:
$S \rightarrow CC$
$C \rightarrow cC/a$
The grammar is
(A) LL (1)
(B) SLR (1) But not LL (1)
(C) LALR (1) but not SLR (1)
(D) LR (1) but not LALR

27. The class of grammars for which we can construct predictive parsers looking k-symbols ahead in the input is called
(A) LR (k)
(B) CLR (k)
(C) LALR (k)
(D) LL (k)

28. A compiler is a program that
(A) Places programs into memory and prepares them for execution.
(B) Automates the translation of assembly language into machine language.
(C) Accepts a program written in a high level language and produces an object program.
(D) Appears to execute a source program as if it were machine language.

Common data for questions 29 and 30:

Consider the grammar
$E \rightarrow TE'$
$E' \rightarrow + TE' \mid \in$
$T \rightarrow FT'$
$T^{1} \rightarrow * FT' \mid \in$
$F \rightarrow (E) \mid id.$

29. Which one is FOLLOW (F)?
(A) {+,), $}
(B) {+, (,), *}
(C) {*,), $}
(D) {+, *,), $}

30. FIRST (E) will be as same as
(A) FIRST (T)
(B) FIRST (F)
(C) Both (A) and (B)
(D) None of these

Compiler Design Test 1

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Which of the following implementation of Lexical analyzer is easy to modify and faster?
(i) Lexical-analyzer by hand
(ii) Lexical-analyzer generator
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

2. Which of the following tasks are performed by a Lexical analyzer?
(i) Identification of Lexemes
(ii) Stripping-out Comments
(iii) Stripping-out white spaces
(iv) Correlating error messages generated by the compiler with the source program.
(A) (i), (ii) (B) (i), (ii), (iii)
(C) (iii), (iv) (D) (i), (ii), (iii), (iv)

3. Which of the following statement is TRUE?
(i) Every LL(k) language is deterministic context-free language.
(ii) Every deterministic context free language is LL(k) language.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

4. Which of the following grammar is LL(3) grammar but not LL(2) and not LL(1)?
(A) $S \rightarrow aS|b$ (B) $S \rightarrow aaS \mid ab \mid b$
(C) $S \rightarrow aaaS \mid aab \mid ab \mid b$ (D) None of the above

5. On errorneous input,
(A) LALR parser makes more moves than LR parser.
(B) LR parser makes more moves than LALR parser.
(C) LALR parser makes equal number of moves as an LR parser.
(D) Unpredictable

6. What kind of conflict does the following grammar leads to?
$S \rightarrow A$
$A \rightarrow xA \mid yA \mid y$
(A) Shift-reduce conflict
(B) Reduce-reduce conflict
(C) No conflict exist
(D) Both (A) and (B)

7. Which of the following statement(s) is/are TRUE?
(i) Synthesized attributes may be calculated only from attributes of children.
(ii) Inherited attributes may be calculated only from attributes of parents.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

8. Which of the following action is not performed by an LL parser?
(i) Matching top of the parser stack with next input token.
(ii) Predicting a production and apply it in a derivation step.
(iii) Accept and terminate the parsing of a sequence of tokens.
(iv) Reporting an error message.
(A) (i), (iv) (B) (iii), (iv)
(C) (ii), (iii) (D) None of the above

9. Consider the following grammar:
$S \rightarrow AcB$
$A \rightarrow aA \mid \varepsilon$
$B \rightarrow bBS \mid \varepsilon$
For this grammar, FOLLOW(B) is
(A) $\{a, \$\}$ (B) $\{a, c\}$
(C) $\{a, c, \$\}$ (D) $\{c\}$

10. Which of the following statements is FALSE?
(A) Every LR(0) grammar is in SLR (1).
(B) Every SLR (1) grammar is in LR (0).
(C) Every SLR(1) grammar is a canonical LR(1) grammar.
(D) Every LR(1) grammar is not necessarily SLR(1).

11. Which of the following grammars for $\{a^n b^{n+k} | n, k \in N\}$ are in LL(1)?
(i) $S \rightarrow PQ$
$P \rightarrow aPb \mid \varepsilon$
$Q \rightarrow bQ \mid \varepsilon$
(ii) $S \rightarrow aSb| T$
$T \rightarrow bT| \varepsilon$
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

12. Based on which of the following parameters does a LR(k) parser performs reduction?
(i) The complete left context
(ii) The reducible phrase itself
(iii) The k-terminal symbols to its right
(A) (i), (iii) only (B) (ii), (iii) only
(C) (i), (ii),(iii) (D) (i) only

13. After removing left-recursion from the following grammar the resultant grammar will be:
$P \rightarrow P + Q \mid Q$
$Q \rightarrow \text{int} \mid (P)$
(A) $P \rightarrow Q + Q$
$Q \rightarrow \text{int} \mid (P)$
(B) $P \rightarrow QP^1$
$P^1 \rightarrow +QP^1 \mid \varepsilon$
$Q \rightarrow \text{int} \mid (P)$

(C) $P \rightarrow QP^1$
$P^1 \rightarrow +QP^1$
$Q \rightarrow \text{int} \mid (P)$

(D) $P \rightarrow Q + P^1$
$P^1 \rightarrow Q + P^1 \mid \varepsilon$
$Q \rightarrow \text{int} \mid (P)$

14. Consider the following grammar:
$S \rightarrow PQRt$
$P \rightarrow a \mid b \mid \varepsilon$
$Q \rightarrow c \mid d \mid \varepsilon$
$R \rightarrow e \mid f$
For this grammar, FIRST(S) is
(A) $\{a, b, c, d, e, f, \varepsilon\}$ (B) $\{a, b, c, d, e, f\}$
(C) $\{a, b, t\}$ (D) $\{a, b, c, d\}$

15. Consider the following grammar, G:
$S \rightarrow (L) \mid a$
$L \rightarrow L, S \mid S$
Which of the following is TRUE?
(i) G is not suitable to be parsed using recursive descent parsing.
(ii) FIRST (S) = FIRST (L) = $\{(, a\}$
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

16. Consider the following configuration:
$A \rightarrow X_1\, X_2 \ldots X_j, a$
Then which of the following is TRUE?
(i) With SLR(1) parsing we would reduce if the next token was any of those in FOLLOW (A).
(ii) With LR(1) parsing, we reduce only if the next token is exactly 'a'.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

17. Which of the following is FALSE?
(A) An LALR(1) grammar is one which allows a LALR(1) parse table to be constructed with no more than one action per cell.
(B) LALR(1) grammar allow a wider set of structures than SLR(1) grammar.
(C) LALR(1) grammars do not handle some cases allowed in LR(1) grammars.
(D) None of these

18. Identify the correct statements from the following:
(i) LALR(1) is a subset of LR(1).
(ii) LALR(1) is a super set of SLR(1).
(iii) A grammar that is not LR(1) may LALR(1).
(A) (i), (ii) only (B) (ii), (iii) only
(C) (i), (iii) only (D) (i), (ii), (iii)

19. Based on the following grammar,
$E \rightarrow E + T \mid T$
$T \rightarrow T * F \mid F$
$F \rightarrow (E) \mid id$
What is the closure $(\{T \rightarrow T \bullet * F\}$?
(A) $\{T \rightarrow T \bullet * F\}$
(B) $\{T \rightarrow T \bullet * F\ T \rightarrow \bullet F\}$
(C) $\{T \rightarrow T * \bullet F\ F \rightarrow \bullet (E)\ F \rightarrow \bullet\, id\}$
(D) $\{T \rightarrow \bullet\, T * F\}$

20. Consider the following grammar:
Stmts' $\rightarrow$ Stmts
Stmts $\rightarrow$ Stmt | Stmts; Stmt
Stmt $\rightarrow$ $Id = E$ | Print E
$E \rightarrow Id \mid E + E \mid (E)$
What does the closure set of the following rule will include?
Stmts' $\rightarrow \bullet$ Stmts
(A) Stmts' $\rightarrow \bullet$ Stmts
(B) Stmt's $\rightarrow \bullet$ Stmts
Stmts $\rightarrow \bullet$ Stmt
Stmts $\rightarrow \bullet$ Stmts ; Stmt
Stmt $\rightarrow \bullet$ $id = E$
Stmt $\rightarrow \bullet$ Print E
(C) Stmts' $\rightarrow \bullet$ Stmts
Stmts $\rightarrow \bullet$ Stmt
Stmts $\rightarrow \bullet$ Stmts ; Stmt
Stmt $\rightarrow \bullet$ $id = E$
Stmt $\rightarrow \bullet$ Print E
$E \rightarrow \bullet\, id$
$E \rightarrow \bullet\, E + E$
$E \rightarrow \bullet\, (E)$
(D) Stmts' $\rightarrow \bullet$ Stmts
Stmts $\rightarrow \bullet$ Stmt
Stmts $\rightarrow \bullet$ Stmts; Stmt

21. For the following grammar:
$A \rightarrow BCD$
$B \rightarrow Bb \mid \varepsilon$
$C \rightarrow cC \mid \varepsilon$
$D \rightarrow d$
What is FOLLOW (B)?
(A) $\{b, \$\}$ (B) $\{b, c\}$
(C) $\{b, d\}$ (D) $\{b, c, d\}$

22. Consider the following grammar, G:
$S \rightarrow AB$
$A \rightarrow aAa \mid \varepsilon$
$B \rightarrow bBb \mid \varepsilon$
Which of the following statements is TRUE?
(i) G is ambiguous.
(ii) G is not in LL(1).
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

23. Consider the following grammar:
$S \rightarrow a \mid AbC$
$A \rightarrow a$
$C \rightarrow A \mid c$
Which of the following is FALSE?
(A) FOLLOW(S) = $\{\$\}$
(B) FOLLOW(A) = $\{b, \$\}$
(C) FOLLOW(C) = $\{\$\}$
(D) The grammar is in SLR(1).

24. Which of the following is TRUE about LR-attributed grammar?

(i) Attributes can be evaluated in LR parsing
(ii) LR-Attribute grammars are a subset of L-attributed grammars
(iii) LR-attribute grammars are a subset of S-attributed grammars.

(A) (i), (ii) only (B) (ii), (iii) only
(C) (i), (iii) only (D) (i), (ii), (iii) only

25. Which of the following conditions must hold to call a grammar is in SLR(1)?

(i) For any production $A \to x.yz$ in the set, with terminal y, there is no complete item $B \to W$. In that set with 'y' in FOLLOW (B).
(ii) For any two complete productions $A \to X$ and $B \to Y$. In the set, the follow sets must be disjoint.

(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

Answer Keys

1. B	**2.** D	**3.** A	**4.** C	**5.** A	**6.** A	**7.** A	**8.** D	**9.** C	**10.** B

Hints and Explanations

1. Lexical-analyzer generator makes the code easier to modify a lexical analyzer (Since we have to rewrite only the affected patterns).
It also speeds up the process of implementing the analyzer (Since the programmer specifies the software at the very high level of patterns and relies on generator to produce code). Choice (B)

3. LL(k) languages are Deterministic CFLs but there are Deterministic CFL's that are not LL(k). Choice (A)

4. $S \to aS/b$ is in LL(1)
($\because$ By looking single look-ahead, we can decide whether to shift or reduce).
$S \to aaS|ab|b$ is in LL(2).
$S \to aaaS|\ aab|\ ab|\ b$ is in LL(3). Choice (C)

5. On errorneous input, LALR parser makes more moves (i.e., reductions) than the LR parser. Choice (A)

6. Given grammar,
$S \to A$
$A \to xA \mid yA \mid y$
This grammar has shift-reduce conflict.
$A \to y\,.\,A$ || leads to shift
$A \to y.$ || leads of reduce
These productions leads to shift-reduce conflict.
Choice (A)

7. Synthesized attributes are calculated from attributes of children.
Inherited attributes are calculated from attributes of parents or siblings. Choice (A)

8. An LL parser perform the following actions:
(i) Match (ii) Predict
(iii) Accept (iv) Error Choice (D)

9. Given grammar,
$S \to AcB$
$A \to a\,A \mid \varepsilon$
$B \to bBS|\ \varepsilon$
FOLLOW (B) = FIRST (S) U FOLLOW (S)
FIRST (S) = {FIRST (A) – ε} ∪ {c} = {a, c}
Follow (S) = {\$}
∴ Follow (B) = {a, c, \$} Choice (C)

10. LR(0) ⊂ SLR (1) ⊂ CLR (1) Choice (B)

11. Given language:
$\{a^n\, b^{n+k} \mid n, k \in N\}$
(i) $S \to PQ$
$P \to aPb|\ \varepsilon$
$Q \to bQ|\ \varepsilon$
This is LL(1) (No ambiguity, no left recursion).
To derive 'ab':
$S \to PQ$
$\to aPbQ$
$\to ab$.
(ii) $S \to aSb \mid T$
$T \to bT \mid \varepsilon$
To derive 'ab' :
$S \to aSb$
$\to aTb$
$\to abTb$ ($T \to bT$)
(Back track)
(or)
$S \to aSb$
$\to aTb$
$\to ab(T \to \varepsilon)$
∴ (ii) not in LL(1) (as which production to use in some derivation is unknown). Choice (A)

12. All the three parameters are required during reduction in LR(k) parser. Choice (C)

13. Given grammar,
$P \to P + Q \mid Q$

$Q \rightarrow \text{int} \mid (P)$
To avoid left-recursion, replace recursive term with other terms and introduce a new variable as shown below.
$P \rightarrow P + Q \mid Q$ can be written as
$P \rightarrow QP^1$
$P^1 \rightarrow +QP^1 \mid \varepsilon$ Choice (B)

14. FIRST (S) = {FIRST (P) – ε} U {FIRST (Q) – ε} U {FIRST (R)}
$= \{a, b, c, d, e, f\}$. Choice (B)

15. Given grammar is not parsed using recursive descent parsing as the grammar is left recursive.
FIRST (S) = {(, a}
FIRST (L) = FIRST (S) = {(, a} Choice (C)

16. For the configuration,
$A \rightarrow X_1, X_2, \ldots X_j, a$
If 'a' is in FOLLOW(A) then reduce in SLR(1).
If the next token is exactly 'a' then reduce in LR(1).
Choice (C)

18. SLR(1) ⊂ LALR (1) ⊂ LR(1)
If a grammar is not in LR(1) then it is not in LALR(1).
(∵ Conflict exist in LALR also) Choice (A)

19. Given grammar
$E \rightarrow E + T \mid T$
$T \rightarrow T * F \mid F$
$F \rightarrow (E) \mid id$
Closure ({$T \rightarrow T \bullet * F$}) will be {$T \rightarrow T \bullet * F$} only.
To calculate closure we add new productions to the set if the • is before a non-terminal.
(Here • is before '∗' which is a terminal)
Choice (A)

20. Given grammar,
Stmts' → Stmts
Stmts → Stmt | Stmts; Stmt
Stmt → id = E| Print E
$E \rightarrow id \mid E + E \mid (E)$
Closure ({Stmts' → • Stmts}),
will include the productions of Stmts (∵ • is before Stmts)
Stmts → • Stmt
Stmts → •Stmts; Stmt
Now production of 'Stmt' will be included (∵ • is before Stmt)
Stmt → •id = E
Stmt → • Print E Choice (B)

21. Follow (B) = {b} ∪ {FIRST (C) – ∈} ∪ {FIRST (D)}
$= \{b\} \cup \{c\} \cup \{d\}$
$= \{b, c, d\}$ Choice (D)

22. Given grammar G:
$S \rightarrow AB$
$A \rightarrow aAa\mid \varepsilon$
$B \rightarrow bBb \mid \varepsilon$
G is not ambiguous.
(∵ To derive any string only one possible method exists)
G is not in LL(1).
To derive aa.
$S \rightarrow AB$
$\rightarrow aA\ aB$
$\rightarrow aa\ A\ aaB$ (or) $S \rightarrow AB$
(Back track) $\rightarrow aA\ aB$
$\rightarrow aAa\ B$ $\rightarrow aaB$
$\rightarrow aa$ $\rightarrow aa$
∴ G is not in LL(1).
[OR]
To check whether G is in LL(1) or not:
Check whether for all $A \in N$ with $A \rightarrow \alpha_1 \mid \alpha_2 \mid \ldots \alpha_n$ being all A-Productions in G, the following holds:
(i) FIRST(α_1),………FIRST(α_n) are pairwise disjoint.
(ii) If ∈ ∈ FIRST(α_j) for some $j \in [1, n]$ then FOLLOW (A) η FIRST (α_i) = ϕ for all $1 \le i \le n, j \ne i$.
(i) is satisfied.
FIRST (aAa) = {a}
FIRST (ε) = {ε}
(ii) is failed.
FIRST ($aA\ a$) = {a}
FOLLOW (A) = {a, b, \$}
These are not disjoint.
∴ G is not in LL(1). Choice (B)

23. Given grammar,
$S \rightarrow a \mid AbC$
$A \rightarrow a$
$C \rightarrow A|c$
FOLLOW (S) = {\$}
FOLLOW (A) = {b} ∪ follow (C) = {b, \$}
FOLLOW (C) = FOLLOW (S) = {\$}
The grammar is not in SLR(1) , since there is reduce/reduce conflict with the productions.
$S \rightarrow a$.
$A \rightarrow a$. Choice (D)

24. LR-attribute grammar is a special type of attribute grammar. It allows the attributes to be evaluated on LR parsing.
LR-attribute grammar ⊂ L-attributed grammar.
S-attributed grammar ⊂ LR-attributed grammar.
Choice (A)

25. (i) avoids shift-reduce conflict.
(ii) avoids reduce-reduce conflict. Choice (C)

Compiler Design Test 2

Number of Questions: 25 **Section Marks: 30**

Directions for questions 1 to 25: Select the correct alternative from the given choices.

1. Which of the following issues are considered by the run-time environment of a compiler?
(i) Allocation of storage locations for the objects
(ii) Mechanisms to access variables
(iii) Linkages between procedures
(A) (i), (ii) only (B) (ii), (iii) only
(C) (iii) only (D) (i), (ii), (iii)

2. Program data objects (such as global constants) and data generated by the compiler (such as the information to support garbage collection) are placed in which of the following areas of run-time memory?
(A) Code area (B) Static area
(C) Heap area (D) Stack area

3. If an activation of procedure '*A*' calls procedure '*B*' then which of the following is TRUE?
(A) Activation of *B* must end before the activation of *A* can end.
(B) Activation of *A* must end before the activation of *B* can end.
(C) Activation of *A* must end before the activation of *B* can start.
(D) Activation of *B* must start after the activation of *A* can end.

4. Consider the activation of procedure *X* which calls procedure *Y*. the activation of *Y* aborts (i.e., it becomes impossible for execution to continue). Then which of the following is TRUE?
(A) *X* continues execution
(B) *X* ends simultaneously with *Y*
(C) *X* makes '*Y*' to execute
(D) None of these

5. Which of the following is true with respect to an "activation tree"?
(i) Root of the tree is the activation of "main" procedure.
(ii) Nodes of the tree corresponds to an activation.
(iii) At a node for an activation of procedure *P*, the children correspond to activations of the procedures called by this activation of *P*.
(A) (i), (ii), only (B) (ii) only
(C) (iii) only (D) (i), (ii), (iii)

6. The sequence of procedure calls of a program corresponds to which traversal of the activation tree?
(A) In order traversal (B) Pre order traversal
(C) Post order traversal (D) Level-order traversal

7. The sequence of returns of procedures corresponds to which traversal of the activation tree?
(A) In order traversal
(B) Pre order traversal
(C) Post order traversal
(D) Level-order traversal

8. Consider an activation tree '*T*'. Also assumes that the control lies within a particular activation of some procedure, corresponding to a node *N* of the activation tree.
Then the activations that are currently live (or open) are those that correspond to
(A) Node *N* only
(B) Node *N* and its ancestors only
(C) Node *N* and its children only
(D) Ancestors of node *N* only

9. Which of the following tasks is managed by a control stack (i.e., run-time stack)?
(A) Static data and functions
(B) Garbage collection
(C) Procedure calls and returns
(D) All of the above

10. Which of the following field of an activation record will point to the activation record of the caller?
(A) Returned values (B) Access link
(C) Temporaries (D) Control link

11. Consider the following statement :
"It is possible to allocate objects, arrays or other structures of unknown size on the stack".
Which of the following is TRUE with respect to given statement?
(i) This avoids the expense of garbage collection.
(ii) The array or the object needs to be local of a procedure.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

12. Consider the languages which do not allow nested procedure declarations. Then which of the following is FALSE?
(i) Global variables are placed on stack.
(ii) Access links are used for accessing local variables of a procedure.
(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

13. Consider the following procedure:
```
q( )
{
.
.
.
p ( )
```

```
{ .
 .
 .
.
r( )
{
 .
 .
 }
s( )
{ .
 .
 .
}
 }
 t( )
 {
 .
 .
 .
 }
 }
```

What is the nesting depth of procedure '*s*'?

(A) 2 (B) 3
(C) 4 (D) 5

14. Which of the following is attached to each activation record to use normal static scope rule for nested functions?

(A) Access link (B) Control link
(C) Process link (D) Data link

15. Consider a procedure '*P*' which is at the top of the stack with nesting depth 'n_p' and '*P*' needs to access '*x*', which is defined with in some procedure '*Q*' that surrounds '*P*' and has nesting depth 'n_q'. To find '*x*' initially top of the stack is checked and then how many times access links are followed?

(A) $n_q - n_p$ (B) $n_p - n_q$
(C) $n_q - n_p + 1$ (D) $n_p - n_q + 1$

16. Consider a procedure '*p*' which is passed to another procedure '*q*' as a parameters. And *q* calls its parameter. Then which of the following things are passed from caller to called?

(i) Name of the procedure parameter
(ii) Access link of the parameter

(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) None of these

17. Which of the following is FALSE with respect to reference counting?

(i) The reference count of a new object is set to 1.
(ii) The reference count of each object passed into a procedure is incremented.
(iii) Reference counting can be used to collect unreachable cyclic data structures.

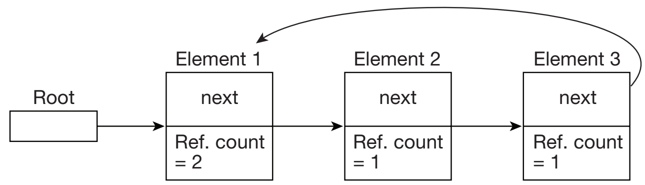
(A) (ii) only (B) (iii) only
(C) (ii), (iii) only (D) (i), (ii), (iii)

18. Which of the following statements is TRUE?

(i) If no references are found to an object then that object is considered as 'garbage'.
(ii) Reference counting garbage collector works in 'incremental' fashion.

(A) (i) only (B) (ii) only
(C) Both (i) and (ii) (D) Neither (i) nor (ii)

19. Consider the following figure:



Each object has its Reference count. If the 'Root' assigned 'NULL' value then which of the following is true?

(i) The reference counts of element 1, 2, 3 will be respectively 1, 1, 1.
(ii) The reference counting garbage collector can consider the elements as garbage.

(A) (i) only
(B) (ii) only
(C) Both (i) and (ii)
(D) Neither (i) nor (ii)

20. Which of the following task is not related to code generator?

(i) Instruction selection
(ii) Register Allocation
(iii) Instruction ordering

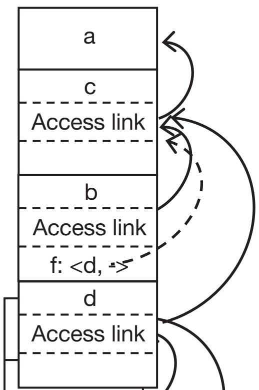
(A) (i), (ii) only (B) (ii), (iii) only
(C) (iii) only (D) None of these

21. Consider the following function:

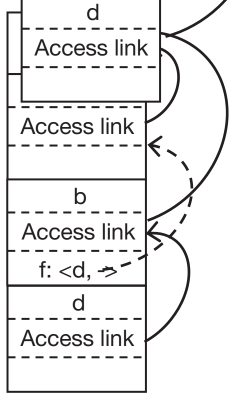
```
fun a(x) =
    Let
      fun b(f) =
      ….f….;
      fun c(y) =
        Let
      fun d(z) = ……
      in
      …..b(d)……….
      end
    in
    ……..c(1)…….
    end;
```

Here function '*a*' consists the functions '*b*' and '*c*' within it. Function '*b*' has function-valued parameter *f*, which is called by '*b*'. Function '*c*' defines within it self a function '*d*' and then '*c*' calls '*b*' with actual parameter '*d*'. Then which of the following correctly shows the access links between the functions?

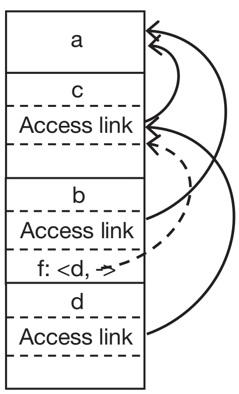
(A)



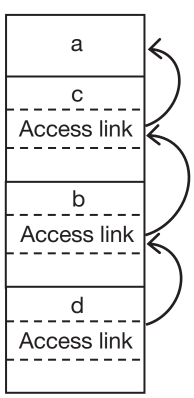
(B)



(C)



(D)



22. The number of non-leaf nodes present in the DAG representation of the following block is:

1. $x = y + z$
2. $y = x - w$
3. $z = y + z$
4. $w = x - w$

(A) 2 (B) 3
(C) 4 (D) 5

23. Consider the following block:

1. $p = q + r$;
2. $q = q + s$;
3. $r = r - s$;
4. $t = q + r$;

Which of the following is TRUE with respect to given block?

(i) DAG representation of given block can identify the common sub-expression of the block.
(ii) The DAG has 4 non-leaf nodes

(A) (i) only
(B) (ii) only
(C) Both (i) and (ii)
(D) Neither (i) nor (ii)

24. Consider the following expression:

$(c + d) - (-(f + g))$

To evaluate the given expression (All operands must be in registers). What is the minimum number of registers required?

(A) 1 (B) 2
(C) 3 (D) 4

25. Construct a syntax-directed translation scheme that takes strings of a's, b's and c's as input and produces as output the number of substrings in the input string that correspond to the pattern $a(a + b)^*c + (a + b)^*b$. For example, the input string '*abbcabcababc*' translation scheme outputs 3(*abbc*, *abc*, *ababc*).

(A) $S_1 \to S_2 a$ $\{S_1.n_1 = S_2..n_1 + 1;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \to S_2 b$ $\{S_1.\ n_1 = S_2.\ n_1 + 1;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3 + S_2.n_2;\}$
$S_1 \to S_2 c$ $\{S_1.n_1 = 0;$
$S_1.n_2 = S_2.n_2;$
$S_1.\ n_3 = S_2.n_3;\}$
$S_1 \to a$ $\{S_1.n_1 = 1;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$
$S_1 \to b$ $\{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0\}$
$S_1 \to c$ $\{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0\}$

(n_1 = count of number of a's to the left of c
n_2 = count of number of a's to the right of 'c',
n_3 = total number of required substrings.)

(B) $S_1 \to S_2 a$ $\{S_1.n_1 = S_2.n_1 + 1;$
$S_1.\ n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \to S_2\ b$ $\{S_1.n_1 = S_2.n_1 + 1;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \to S_2\ c$ $\{S_1.n_1 = 0;$

$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \rightarrow a\ \{S_1.n_1 = 1;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$
$S_1 \rightarrow b\ \{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0\}$
$S_1 \rightarrow c\ \{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$

(C) $S_1 \rightarrow S_2 a\ \{S_1.n_1 = S_2.n_1 + 1;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \rightarrow S_2 b\ \{S_1.n_1 = S_2.n_1;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \rightarrow S_2 c\ \{S_1.n_1 = 0;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \rightarrow a\ \{S_1.n_1 = 1;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$
$S_1 \rightarrow b\ \{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$
$S_1 \rightarrow c\ \{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$

(D) $S_1 \rightarrow S_2\ a\ \{S_1.n_1 = S_2.n_1 + 1;$
$S_1.n_2 = S_1.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \rightarrow S_2\ b\ \{S_1.n_1 = S_2.n_1;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \rightarrow S_2\ c\ \{S_1.n_1 = 0;$
$S_1.n_2 = S_2.n_2;$
$S_1.n_3 = S_2.n_3;\}$
$S_1 \rightarrow a\ \{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$
$S \rightarrow b\ \{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$
$S \rightarrow c\ \{S_1.n_1 = 0;$
$S_1.n_2 = 0;$
$S_1.n_3 = 0;\}$

Hints and Explanations

1. The run-time environment of a complier deals with the issues such as:
(1) Allocation of storage locations for the objects
(2) Linkages between procedures
(3) Mechanisms used by the target program to access variables
(4) Mechanisms for passing parameters etc.
Choice (D)

2. The size of some program data objects and data generated by the compiler can be known at compile time. So they can be placed in static area of run-time memory.
Choice (B)

3. Given, that *A* and *B* are procedures and

```
A ( )
{
.
.
B ( ) ;
.
.
.
}
```

Each time a procedure is called, space for its local variables is pushed on to a stack and when the procedure terminates, that space is popped off the stack.
In given scenario, Activation record of '*A*' created initially. Next *B*'s activation record is created and *B* must end before the termination of '*A*'. Choice (A)

4. If *Y* aborts then *X* also ends simultaneously with *Y*.
Choice (B)

5. Choice (D)

6. The preorder traversal of an activation tree corresponds to the sequence of procedure calls. Choice (B)

7. The sequence of returns corresponds to a post-order traversal of the activation tree. Choice (C)

8. The live nodes are *N* and its ancestors. ($\because$ After return of child nodes only parent nodes will terminate.)
Choice (B)

9. Control stack (run-time stack, manages procedure calls and returns). Choice (C)

10. Control link points to the activation record of the caller. Access link is used to locate data needed by the called procedure. Choice (D)

11. It is possible to allocate objects, whose size cannot be determined at compile time on a stack. This avoids the expense of garbage collecting their space.
But the stack can be used only for an object if it is local to a procedure. (∵ The local data will be inaccessible when the procedure returns). Choice (C)

12. Global variables are allocated in static storage.
Local variables are placed in stack (and accessed using top of the stack). Choice (C)

13. Nesting depth of a procedure is '1' if it is not nested within any other procedure.
If a procedure P is defined immediately with in a procedure Q then the nesting depth of $P = 2$
Here, in given code,
Nesting depth of 'q' = 1
Nesting depth of 'p = 2
Nesting depth of 'r' = 3
Nesting depth of 's' = 3
Nesting depth of 't' = 2 Choice (B)

14. Access links are attached to activation records to use static scope rules for nested procedures. Choice (A)

15. P is defined with in Q. Nesting depth of P is n_p. Nesting depth of 'Q' is n_q.
As P is inside Q,
$N_p \geq n_q$
We need to check $n_p - n_q + 1$ records to identify 'x'.
(one access is already given in problem). Choice (B)

16. The name of the procedure parameter and access link of the parameters needs to passed by caller. Choice (C)

17. Reference counting cannot collect unreachable, cyclic data structures. Choice (B)

18. An object is considered as garbage if it has no references.
